HIGH EXPLOSIVE SHELL MANUFACTURE

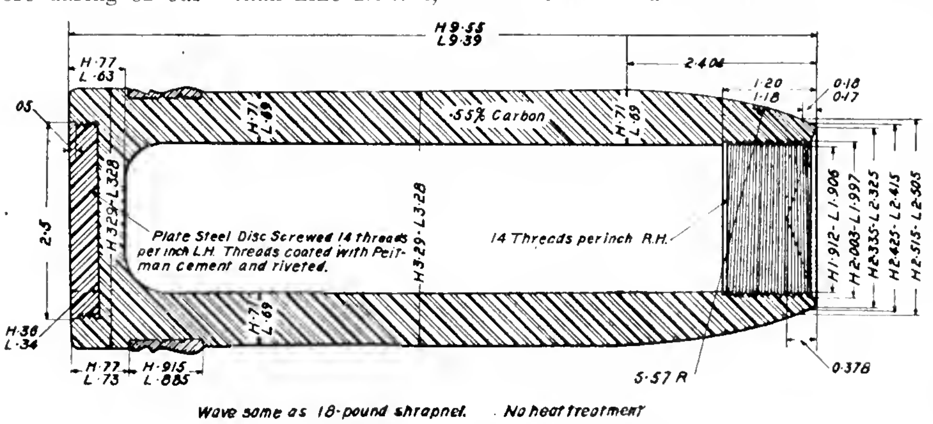
The sudden call from the manufacture of articles of a peaceful commerce to that of supplying the gods of war with provender of a prodigious amount and such as we never dreamed of producing, has been met by the administrations of our iron and steel industries in a manner that demands whole-hearted admiration for their enterprise, capacity, resourcefulness.

THE problems facing machine shops in Canada to-day are perhaps greater than any they have previously had to solve. Even the layman is not very hard pressed to imagine the troubles, difficulties, disappointments, and reverses that beset the inauguration of a new industry. When, however, this industry has to be developed on a large scale against odds that have combined themselves in such a way as to make the successful outcome almost impossible, it is surely a rare tribute to our manufacturers, their executive staffs and the workmen who have put the plans into being, that highly satisfactory results have been and are being attained.

The proposal to make shells for the British guns was placed before the Canadian engineering community with but scant notice. The more daring of our mechanical men, however, jumped at the opportunity to get into this work, being spurred on by two primary motives—first, the pariotic, and, secondly, the chance to get their plants running again at full capacity. Canada had been in the throes of a very dull industrial period, and thus, when new equipment came to be ordered, it was found that the machine tool manufacturers had but little to offer from stock, besides being in no way prepared to make good deliveries, because their plants were mostly all working on short time, and could not be put on full time at a moment's notice.

The large number of Canadian shops that went into the shell business fairly swamped the machine tool manufacturers with orders for equipment. Canadian orders were not, however, the only ones upon which the machine tool people were working, because huge orders from the European belligerent powers were also being placed with them. The result was that Canada found herself dependent upon her own resources more or less. Realizing this, our engineers and plant superintendents rose to the occasion and fitted up lathes and various other machines at their disposal to take care of shrapnel shell contracts.

Here, after a period of not longer than nine months, we find that the difficulties of making shrapnel shells have not only been surmounted, but our organization has been so perfected that a wonderful output is now being obtained. The ingenious methods adopted by our men in attaining this end have excited much admiration on the part of our American cousins, who themselves have earned a considerable reputation for smartness. However, the modesty of the Canadian engineer does not permit him to congratulate himself unduly, and anyway, were he so inclined now, it would be well-nigh impossible, because his shops are going night and day. Any spare time that falls to his lot is usually spent in obtaining a well-earned rest, and he is not much disposed to talk "shop."



BRITISH 18-POUNDER HIGH EXPLOSIVE SHELL.

High Explosive Shells.

Lately a new problem has been presented to our machine shops, involving the manufacture of the lyddite or high explosive shell. It must not be thought because the lyddite shell is in some cases of like diameter that it is similar in manufacture to the shrapnel. It is an entirely different proposition, and the purpose of this article is to point out the main differences. There are two sizes of lyddite shells now being manufactured in Canada—the 3.3-in. and the 4.5-in. shell. The former is known as an 18-pounder and the latter as a 35-pounder. These two shells each require a vastly different plant to that for shrapnel, also they are being machined along entirely different lines.

Let us take first the "three-point-

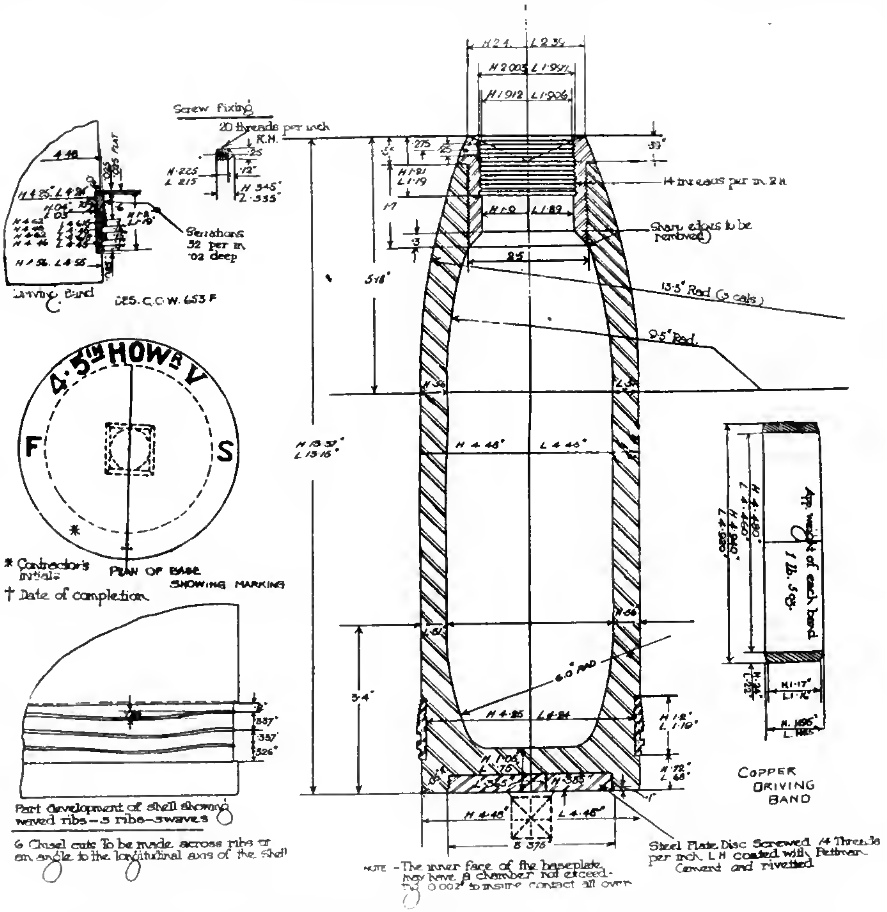
three'' lyddite shell. This finds its way to the machine shops, not as a forging, but as a piece of bar stock cut to rough length. The preliminary operations now in vogue in the various shops are almost identical, but differ from each other in sequence. The order of these operations, however, makes but little difference; therefore one of the most common series will be outlined.

The shell is centred, and is rough-turned the whole length with the exception of that portion upon which a driving dog is placed or a chuck grips it. The bar stock is about $3\frac{3}{4}$ inches in diameter, and the finished diameter is "three-point three" inches, so that nearly a quarter of an inch cut of metal has to be removed from each side of the bar. This metal is taken off and the base of the shell finish faced as far in as the tail centre will allow. The base end of the shell is then finish turned for a short distance, which distance is sufficiently far up to meet the driving band recess. Forming the radius on the corner of the base follows. All of the foregoing is done usually on one lathe.

The next operation is the machining of the driving band groove. Sometimes this operation is accomplished on the same lathe as the rough-turning, and in other cases it is accomplished on another machine. The groove is exactly similar to that on the eighteen-pounder shrapnel.

If this method of taking care of the primary operations has been followed, the next procedure is that of drilling out the shell interior. Rigid drill presses are used almost universally in this process. Sometimes a small drill is used to take a preliminary cut, but in many instances the large roughing drill is put down first.

In some shops drilling out the body is the first operation, the rough-turning being done with the shell mounted on an expanding arbor. When this plan is adopted, another operation is also accomplished, i.e., the machining of the recess in the base. This is possible because the end of the shell is not carried on a tail-stock centre.



Q.F. HIGH EXPLOSIVE 4.5 INCH HOWITZER SHELL, MARK V/L/, FORMED FROM STEEL BILLET 4.8 INS. DIA. BY $9\frac{1}{2}$ INS. LONG AND WEIGHING 49 LBS. WEIGHT OF FILLED SHELL 35 LBS. PLUS OR MINUS 9 DRS. WEIGHT OF BURSTING CHARGE (TROTYL), 4 LBS.

The reason for machining a recess in the base is not apparent to the casual observer, the idea, however, being to reinforce the base with a forged base plate. The shell case, it must be remembered, is made from bar stock, and there might be a pipe in the central portion. If this pipe did exist, it might, upon firing, ignite the high explosive charge in the shell before it left the muzzle of the gun, such a result being naturally very disastrous to not only the gun, but the gunners. The base plate is, therefore, a forging, and is screwed in the base recess very securely.

The next operation is the finish boring, the shell being bored the required depth and the bottom of the bore formed. A thread is also cut on the inside of the nose for about a distance of an inch and a half. This thread is cut from a bore the same size as the straight bore, therefore a recess has to be formed to relieve the thread cutter. The specifications call for this, and practice also demands it. This is a right-hand thread cut with fourteen threads to the inch. Taps have not been found to give equal satisfaction on this operation as they have done on the inside of the noses of shrapnel shells. As a consequence, the practice of milling the threads is receiving considerable attention at present, and gives promise of handling the job satisfactorily. Some firms have built small millers for this purpose, and a number of Canadian firms are also putting on the market a line of machines to accomplish this milling.

After being bored and the nose tapped, the shell passes on for the finishing and tapping of the recess in the base. The latter is tapped out for about three threads, and, here again, relief must be provided for the cutter. This base recess thread is left-hand, of fourteen threads to the inch, and is also being milled out rather than tapped. As an extra precaution, however, sizing taps are run down into both the nose and the base, these taps being usually specially made. The shanks are long and round, and pass through a guide bearing which is bored out of the same casting at the same setting as the locating portion of the chuck which clamps the shell solidly for this particular operation. Thus the tap can never get across a thread or spoil a shell.

Rough turning and forming the taper in nose of the shell, when the boring and the tapping of the nose is accomplished, are being featured; but this is, of course, determined by the nature of the tooling placed on the various machines.

The next operation is the finish turning and forming of the shell nose. This is accomplished on engine lathes in like manner to that employed on similar operations on the shrapnel shell. A forming cam is bolted to the back of the lathe and the cross-feed is disconnected. The cross slide has a fixture attached to it which registers against the formed cam, the cross slide being kept always in register by means of springs or by weights suspended from an attached wire rope. All adjustments of the tool are made by means of the compound rest of the machines.

No heat treatment is necessary with this shell. To many manufacturers this will be welcome, as considerable difficulty has been experienced with same in the production of shrapnel. However,

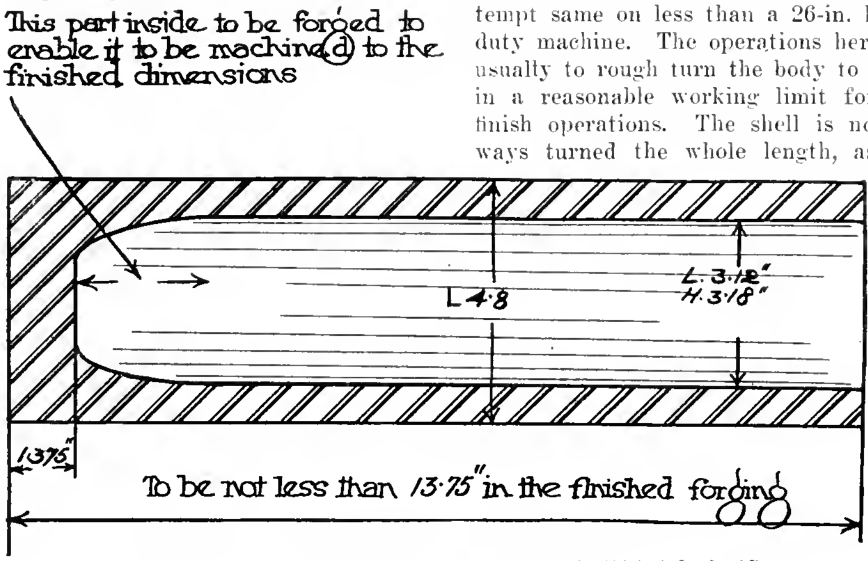
another operation is substituted which, to a certain extent, is as great a source of trouble, as far as the loss of time, at least, is concerned. This consists of varnishing the interior bore of the shell and placing the latter in an oven for a period of eight hours, during which period the shell must be kept at an even temperature of 300 degrees F. Various types of furnaces are in use, some of which are electric, others oil, and others gas, etc. As the heat is not excessive, no very great difficulties are experienced in the operation of these furnaces.

The copper driving bands are pressed on in a manner similar to that practised in the 18-pounder shrapnel shell, and the band turning is accomplished likewise.

4.5-in. Shell Production.

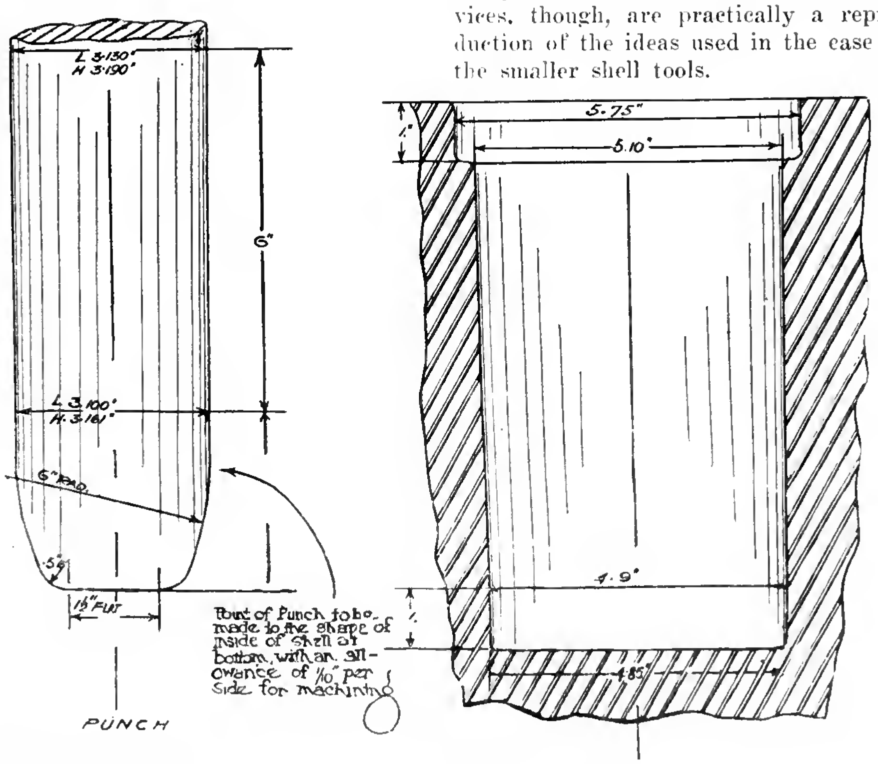
The "four-point-five" lyddite shell is received by the shops in the form of a forging and not as bar stock. The preliminary operations consist of cutting off the open end of the forging and rough facing the base end. This forging is heavier than one would imagine, and an especially heavy cutting off machine is required. A heavy lathe fitted with a special chuck very strongly made gives about as good service as any.

The facing of the base is done in two ways. If an expanding arbor be used in the rough-turning operation it is not probably necessary to have a centre in the base end, but, if the rough turning is done with a self-centering chuck, the outer end must be carried in a centre of some description. The outer end is often carried in a tail-stock centre, even if an expanding arbor be used to hold the shell in the case of the rough turning. The base of the shell must thus be faced in a lathe if a centre is to be carried. This operation cannot be performed on a milling machine or boring mill in a jig, as has been the practice with shrapnel shells.



Q. F. HIGH EXPLOSIVE 4.5 HOWITZER SHELL FORGING.

On account of the heavy turning, it is better to work with the outer end carried in a centre to absorb all spring of the tool and fixtures. The rough turning is accomplished on an engine lathe, and it does not seem very practical to attempt same on less than a 26-in. heavy duty machine. The operations here are usually to rough turn the body to within a reasonable working limit for the finish operations. The shell is not always turned the whole length, as the open end may be grasped in a chuck. The base end is usually finish turned up to the metal left on the base in which the centre is carried. This finish operation is, of course, carried far enough to be in that portion of the metal which is later removed when the recess in the base is cut out.



APPROXIMATE SIZES OF PUNCH AND DIE FOR 4.5 HOWITZER SHELL FORGINGS.

The shell is finish turned up as far as the driving band groove, then the radius of the corner of the base of the shell is formed. The driving band groove can be rough turned and formed here if wished. The tools are carried in a heavy revolving tool holder.

The shell is next bored, a heavy chuck being used for this work, placed on, say, a heavy duty 30-in. lathe. It is not advisable to use a smaller machine. Engine lathes are by far the best to use, a heavy turret being mounted on the cross slide. There should be four bars for boring. A roughing cutter should be put in to bore the straight portion of the bore from the nose inward. It may here be noted that 4.5-in. lyddite shells are bored all the way to the base and finished all over.

A roughing cutter should next be put in to form the bottom of the bore, these being formed cutters with two cutting edges. It helps to have them gashed for chip clearance. The finish cutters should not, of course, have chip clearances provided. The bars should be as rigid as possible, and it is right here, in this boring operation, that the greatest power and rigidity is needed.

After boring, the driving band groove is cut, the groove being considerably wider than the "three-point-three" groove. There are three waved lines in the bottom of the groove, these being formed from a three-point face cam on the face plate of the lathe. Quite as many devices for machining this groove have been developed and operated as have been in the case of the 18-pounder shrapnel and lyddite shells. All the devices, though, are practically a reproduction of the ideas used in the case of the smaller shell tools.

The next operation is that of nosing the shell. It has been found that it is rather expensive to heat the big shell in a lead pot. There is something in the neighborhood of three-quarters of an

inch of metal to heat and a great deal of lead is lost by oxidation. Oil furnaces seem to have become popular to accomplish this work, several being now on the market. To nose the shell, various sizes of presses have been recommended. It seems that a press of about 100 tons capacity is necessary, although some makers are advocating a press of 150 tons. Bulldozers and steam hammers have been more or less successfully employed, but just what type of machine will be the most popular is hard to suggest at the moment. However, the man who buys a hydraulic press of 125 tons capacity will not be left very far behind in the work, although there are no doubt many other press specialties that will give quite as good results. It is not considered necessary to even semi-anneal the noses after the bottling-in process, as the metal is so thick that there is not much tendency to chill.

The nosing of the shell is immediately followed by the finish machine operations on the nose. For a distance of an inch and one-half back, the nose is bored straight, then the shell is turned and formed inside. This has to be performed with much greater accuracy than the similar operation on shrapnel shells. The interior curve has to run into the straight bore very smoothly, and not the slightest semblance of a shoulder must be shown. The interior of the shell is later varnished and baked. This varnish or enamel is to keep the explosive lyddite from coming in contact with the steel shell, for when lyddite comes in contact with the steel a chemical action ensues, which destroys the explosive properties of the lyddite. Hence, all shoulders are to be avoided in the inside of the shell, these having a tendency to cause the varnish to flake and expose the steel.

The nose of the shell is finally faced and the outside of it rough turned and formed. To accomplish this, the shell is usually held in a chuck, which grasps it for nearly its whole length, and holds it rigidly. These operations are very similar to those on shrapnel shell. The straight bore of the shell is, however, much deeper than in the case of shrapnel, and this feature makes it rather difficult to tap-thread nose with a collapsible tap. As in the case of the recess in the base, the thread miller is here used to advantage.

In the boring out of the base, the shell is simply grasped in a long chuck and held there securely. Various types of tools are used to accomplish this work, which amounts to a simple recess about three-eights of an inch deep and 3⅜ inches in diameter. The thread is milled in the recess after a relieving groove has been cut.

Next the shell is finish-turned, a collet chuck being generally employed to grasp the shell base, and a threaded centre being screwed into the nose. This centre is supported by the tail spindle. The base of the shell has been finish-turned, as may be remembered, as far up as the driving band recess. A formed cam is attached to the rear of the lathe, and the cross slide disconnected. Weights suspended from wires attached to the cross slide keep the cross slide, which carries the tool, in register with the forming cam, and thus the profile of the nose is turned.

The copper band is next pressed on in machines similar to those used for the smaller lyddite and shrapnel shells. Then the bands are turned. The shell is chucked and a roughing copper band cutter is put into the work. Next a formed finish tool is used.

CANADIAN SHELL COMMITTEE.

The personnel of the committee entrusted with the placing of orders for shells, etc., and the inspection and shipment of same is representative of both Canadian military and manufacturing interests, and is individually as follows:

David Carnegie, M.I.C.E., Ordnance Advisor.

Col. Alexander Bertram, Chairman of Committee.

Brig. Gen. T. Benson, Master General of Ordnance.

Lieut.Col. Thomas Cantley.

Lieut.-Col. C. G. Harston, Chief Inspector of Arms and Ammunition.

George W. Watts.

Lieut.-Col. F. D. Lafferty, R.C.A., Supt. Dominion Arsenal.

E. Carnegie.

The Shell Committee Headquarters is Ottawa.

The base plates are next screwed in place, but first let us make mention of the machining of these forgings. The back of the disc is faced, leaving the centre about two thousandths higher than the edge, the latter being turned straight. Next the edge is threaded. Machines to accomplish this work at one setting are being designed. The thread is being in many cases milled, followed by sizing dies.

The base plates are screwed home with huge wrenches working on the square shank of the forging. Next the base plate is faced off flush with the base of the shell and peined. The shell is then varnished on its interior, and the varnish is allowed to bake in an oven for eight hours at 300 degrees F. The shell is afterwards removed from the furnace and the brass socket screwed in, the later being afterwards turned. The shell is next chucked and the brass socket formed to a curve, which is a continuation of the curve of the steel nose. When this operation is completed the shell is ready to be painted, after which it is ready for shipment.

SHELL SUPPLY—A PATRIOTIC OFFER.

THE Glasgow and West of Scotland Armaments Committee have received a most patriotic offer from G. & J. Weir, Ltd., Cathcart, makers of "Weir" pumps and other specialties, who have undertaken to produce an unlimited quantity of shells at net cost. The offer was contained in a letter signed by W. Weir, one of the directors and, in this it was pointed out that while it was proposed to establish a national shell factory in Glasgow, his firm had the nucleus organization and the necessary experience, so that it would be much simpler to increase their production than to organize an entirely new producing unit. The letter also quoted the following resolution, which had been unanimously adopted by the directors of the firm:—

"It is hereby agreed that until the conclusion of the war all profits arising from the manufacture of shells under present contracts, after deduction of the necessary allowances for establishment charges and capital expenditure, shall be handed over to certain of the various organizations carrying out relief work or Red Cross work which the war has necessitated, and which are supported by voluntary subscription. When the contracts in question are completed, the different shell plants will be available to produce shells for the Government at net cost, and if required all such future production shall be carried on in conjunction with the proposed Glasgow National Shell Factory."

The firm also offered to extend their plant and machinery for shell production, and on completion of present contracts to devote machinery and labor to the machining of shells produced by the proposed Glasgow National Factory, or generally to work in conjunction with the same under whatever conditions might be suitable.

The committee expressed its high appreciation of this spontaneous offer, and decided to bring it before the notice of the various interests concerned. Detailed information in regard to the proposed national factory was submitted to the committee, and the scheme was remitted to the Shell Sub-Committee for investigation and report.

H. E. Shells Displace Special-Purpose Machinery Output

Staff Article

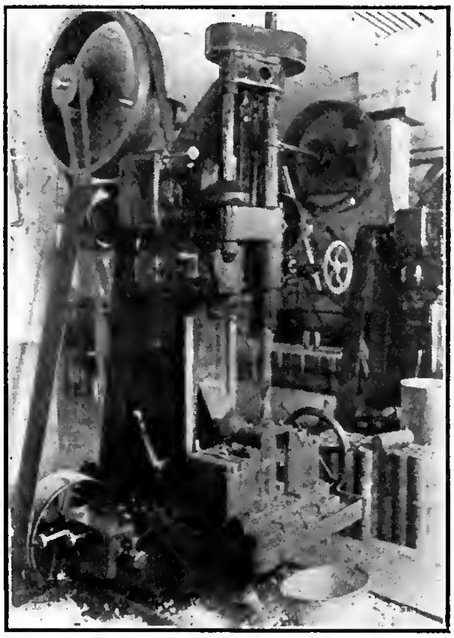
The plant which forms the subject of this article was among the first in Canada to undertake the production of 18-pdr. lyddite shells. Being accustomed, however, to manufacture machinery for special duty, little, if any difficulty was experienced in tackling successfully these war-time commodities. In addition to designing several ingenious fixtures and tools, a number of special machines have also been built and marketed for the work.

THE principal features with regard to the physical properties of high explosive shells having been dealt with more or less fully in another article, it is hardly necessary to reiterate here what has already been said. The manufacturing methods adopted at different plants vary according to conditions prevailing, and also according to the ideas of those responsible for the output administration. High explosive shell production is yet more or less in its infancy in Canada, and it, therefore, remains to be seen to what extent equipment and methods will ultimately become standardized.

As the industry develops, new methods and machine equipment and tooling will no doubt be introduced, and it is here where the chief interest lies, especially for those contemplating engaging in this business. The manufacture of high explosive shells is at present to some extent in the experimental stage, at least as regards some operations, although those concerns at present making this type of shell are obtaining satisfactory results. The whole question of making high explosive shells is full of interest and developments are sure to be followed closely. The pioneers in this business have shown considerable courage and resourcefulness, and are doing much to help those who for various reasons have not meantime got started.

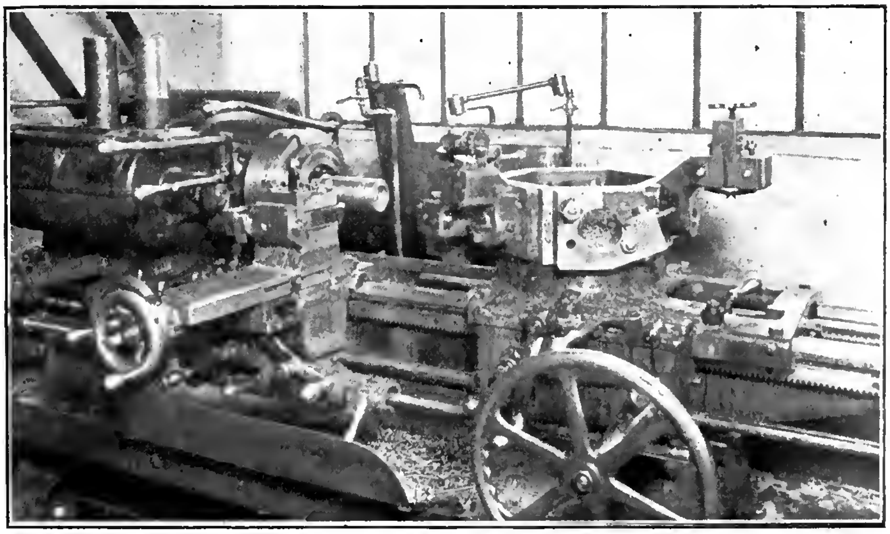
Drilling Bar Stock.

In a number of plants the initial operation consists of cutting the bar stock to the approximate length, but in this particular shop the operation is omitted at this stage, the bar being cut to length later. The first operation consists of drilling the hole in the bars, afterwards reaming out to the finished diameter with the exception of that part at the nose which has been threaded. Six high-speed vertical drilling machines are installed for this work, five furnished by Baker Bros., Toledo, Ohio, and one by the Foote, Burt Co., Cleveland, Ohio. The "Baker" drills are all of the same type and the Foote-Burt is in measure very similar. Three of these machines are used for drilling, two for reaming and one for finishing the bottom of the hole after drilling and preparatory to reaming. The bottom of the hole after being drilled is, of course, V-shaped, and has to be machined to remove some of the metal so that the reamer can make the finishing cut in the same operation as the inside of the hole is finished.



DRILLING-OUT BAR STOCK.

All the drilling machines are equipped with precisely the same type of vise for holding the bar stock during the operation. The vise is a box-shaped casting fastened to the drill table. It has four jaws, two on each side, which conform to the shape of the bar. The jaws are operated by a spindle, with right-hand threads moving one set of jaws and left-hand taking care of the set on the other side. Thus, when the operator turns the hand wheel on this spindle, the jaws close in on the bar stock, which is held vertically. The bars are 9¾ in. long by 3½ in. diameter, the hole being approximately 1⅞ in. diameter. The bars are first of all drilled, and, to ensure the drill being central at the beginning of the cut, a steel guide collar is placed in the hole in top of the fixture, the collar being removed after the drill has made a fair start. After being drilled, the bar is removed to another drilling machine to have the bottom of the hole roughed out preparatory to reaming. The bar is now reamed out on another drilling machine, this constituting the finishing cut for the hole, with the exception of that part at the nose which is afterwards threaded. A long twist drill is used for drilling and a short reamer with a long shank for the reaming operations. The bars are next gauged for correct depth and diameter of hole, and taken over to the turret lathes for the succeeding operation. Twist drills and reamers, supplied by the John Morrow Screw & Nut Co. are used extensively at this plant for this operation.

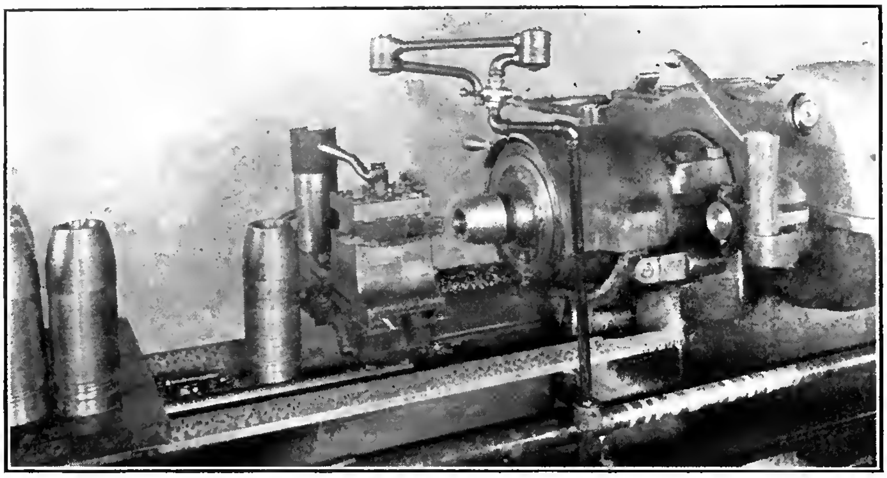


ROUGH TURN BAR, ROUGH TURN RECESS IN BASE, GROOVING, UNDERCUTTING AND WAVING.

Rough Turning Bar, Grooving, Waving, Dovetailing and Recessing Base.

Considerable progress is made in this operation, which consists of rough turning the bar, roughing out

the recess in the base, grooving, forming the wave lines, undercutting and facing up the base. Five turret lathes, furnished by the Warner & Swasey Co., Cleveland, Ohio, are installed for the work. Their tooling was, of course, designed for handling this type of shell. These lathes are equipped with universal chucks, carrying a three-point cam on their face, and have, in addition, an expanding mandrel to ensure that the bar is set in the lathe in alignment with the hole, so that, after machining, the shell may be as concentric as possible. At the extreme end of the mandrel is a projection, behind which is a spring. There are also three stops near the end of the mandrel. When setting the bar in the lathe, it is placed in the chuck over the mandrel and pushed home by a long bar stop on one corner of the turret. This action presses in the projection at end of mandrel, and at the same time forces out the three stops against the inside of the bar, thus setting the bar in alignment and in the correct position, and at the same time helping to hold the bar rigid while being machined. The chuck is then tightened up and the turret advanced towards the work.



ROUGH TURNING SHELL NOSE.

The first turret face holds a fixture with three arms, two having a roller each and the third a cutting tool. The rollers hold the bar steady while a roughing cut is made along the bar. The second turret face holds a fixture with two rollers, similar to No. 1, and has an end mill in the centre. At the side of the mill is a small cutter for roughing the base outside. The rollers hold the bar steady while the end mill roughs out the recess in base. At the same time, the small cutter at the side finishes the base face.

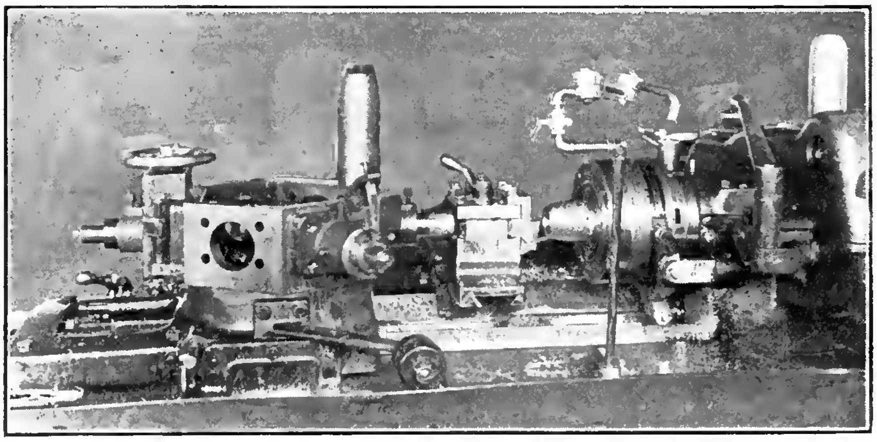
The tool holder on the cross slide, which is fitted up in a very ingenious manner, is now brought into action. On one side of the tool holder is the grooving cutter and a hook-nosed tool for finishing the base. On the reverse side is the waving tool. The tool holder is turned round by the operator as required. Of these two settings, the first mentioned is now brought into operation. The grooving cutter is so made that while forming the groove, the corner of base is rounded off, and at the same time the tool at the side of cutter finishes up the end of base. When grooving, sufficient metal is left to form the wave lines. The tool holder is now swung round for the waving operation. The waving is done by means of a sliding bar in a block held in the tool holder on the cross slide. At one end of this bar is a roller which runs up against the face of the cam fastened to the chuck, this being made so as to generate the required form to the wave. The roller is held up against the face of the cam by a strong spring inserted in the under part of sliding bar. A cutter of suitable shape is held in the sliding bar and is adjustable. In operation, the saddle is moved along until the roller is up against the cam, and then locked. The wave lines are then formed.

The third turret face holds a fixture with a cutter which finishes the base at the side. The fourth turret face holds the dovetailing fixture, which is above the work when in operation. This consists of two small holders working in diagonal slides, each holding a small hook-nose cutter. The turret is moved forward until the cutters are in the desired position over the groove and the operator feeds the cutter in a downward direction by means of a hand wheel. This operation finishes the groove, which is now ready for the copper driving band to be pressed on at a later stage. The feeds for the turret tools are controlled by feed rods at the front of the lathe running from the speed box. All stop motions are controlled from a screw rod located under the turret with a set of stop dogs, one for each turret operation.

Rough Turning Nose.

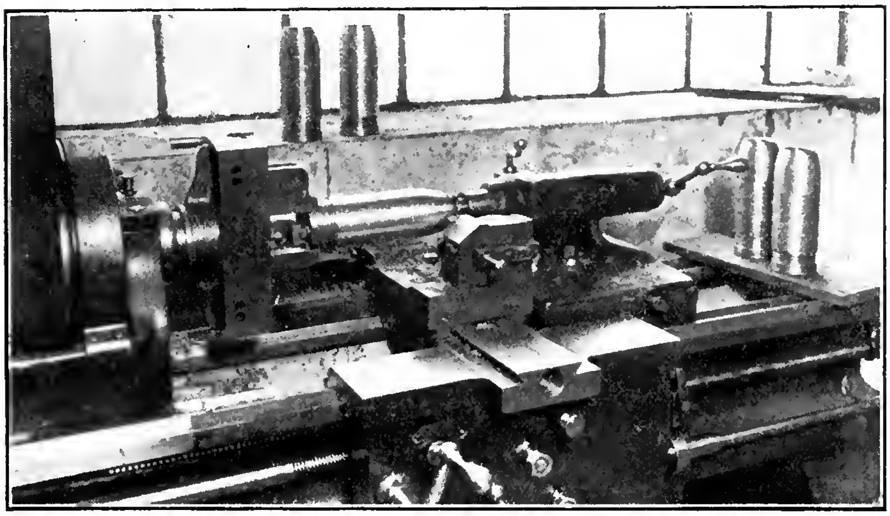
Upon completion of the foregoing operation, the shell nose is rough turned. The end of the bar at this stage is square, no machining having yet been done on it, therefore considerable metal has to be removed before the nose assumes its final shape. To facilitate the work then at a later stage, the nose is now rough-turned or "hogged"—that is, two heavy cuts are taken off so that an ordinary roughing cut only is necessary at the next operation, which simplifies the tooling.

This "hogging" is done on a Warner & Swasey turret lathe, the same type of machine as is used for the previous operation, except that a cam attachment is added and the saddle made to suit. The turret, however, is not used, the work being done by an ordinary turning tool located in the tool holder on the slide rest. In this case, the turret lathe is equipped with a collet chuck operated by a draw-back mechanism. To obtain the profile for the nose, a cam fixture is attached to the bed of the lathe at the front and under the saddle; the latter is specially constructed for the work and overlaps the cam. A roller on the slide rest passes through a slot in the saddle and engages with the cam underneath.



ROUGH TURNING OUTSIDE OF NOSE, REAMING INSIDE OF NOSE, FORMING BEVEL, AND FUSE PLUG SEAT, CUTTING RECESS IN NOSE.

The cut is started at the end of nose and the tool travels inwards, forming the nose to the required profile. Sufficient metal is left to allow for a roughing cut at the next operation. An engine lathe, supplied by Prentice Bros., Worcester, Mass., is also used for "hogging" the nose. In this case the cam is at the back of the lathe fixed to a bracket attached to the bed. A compound slide rest has an extension with a roller engaging with the cam. The lathe is equipped with a standard tool holder and turning tool. The method of procedure is the same as stated above, and the same amount of metal is removed.



FINISH TURNING SHELL BODY OUTSIDE.

Rough Turning Nose, Reaming Nose Inside, Cutting Fuse Plug Seat and Recess in Nose.

Up to this point no work has been done on the inside of the nose since the hole was drilled at the first operation. At this stage the bevel or outside part of fuse plug seat at the nose is formed, and the nose is rough turned outside preparatory to the finishing cut at a later operation. That part of nose which has to be threaded is reamed out and the fuse plug taper seat at nose is formed at the same time. Finally the recess is cut inside nose about 1½ in. from the end. This operation is performed on a Warner & Swasey turret lathe of identically the same type as used in the two preceding operations. The lathe is equipped with a collet chuck operated by a draw-back mechanism.

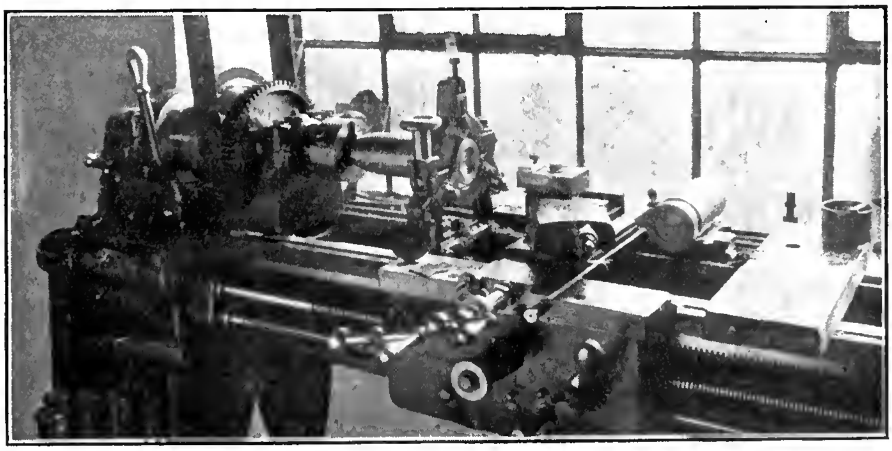
The operator places the shell in the chuck, the correct location being determined by a stop on turret face, the turret being moved up against the shell when setting. On the slide rest is a tool holder, one face holding a cutter for forming the bevel on the outside of the nose. The reverse face of the tool holder has a tool for rough-turning outside of the nose. The first of the above-mentioned tools is now moved towards the work and the bevel on the outside of nose is formed. A bar stop on lathe regulates depth of cut. This bevel forms the outside seat for the fuse plug. The tool holder is next swung round and a roughing cut made on the outside of the nose. To obtain the correct profile for this while being turned, the same cam and saddle arrangement are used as in the previous operation.

The hole inside the nose is now reamed out by a reamer fixed in the second turret face. Above the reamer, held in a fixture, is a tool which finishes the bevel on nose outside. At the same time, a small cutter at the side of the reamer forms the fuse plug taper seat. The turret is then swung round to the third position for cutting the recess in nose, in which the threads finish. The fixture held in the turret face consists of a vertical slide, on which is a bar with a small cutter at the end, and on the bar is a collar for giving the correct location for the recess. The turret is moved forward until the collar is up against the nose. The cutter being now in position, the operator turns a hand-wheel above the fixture, and the cutter forms the recess, a stop on the fixture regulating the depth of cut.

Finish Turning Outside Shell.

The next operation consists of finishing the outside of the shell from the groove to the bevel at the end of nose. It will be remembered that the side of shell between the groove and base has already been finished. Two engine lathes, built by F. E. Reed & Co., Worcester, Mass., are installed for this operation. The base of the shell at the back of groove is held in a chuck with two jaws, leaving the rest of the shell clear to be machined. The correct distance is obtained by means of a stop located between the jaws. At the tail-stock end the shell revolves on an expanding centre specially designed for this work. The outside of this centre is a sliding fit in the nose of shell, and the inside is tapered to suit the tail-stock centre. The centre, being of the expanding type, tightens up when pressed in.

The profile on the nose of shell is obtained by means of a cam fastened to a bracket at the back of the lathe and attached to the bed. On the saddle is a specially designed cross slide, the front part of which extends over the cam, and has a roller underneath for engaging with the cam. The tool holder is a special device, part of it being solid with the cross slide. It holds a vertical turning tool, and has a regulating screw for making adjustments to the tool. The cut is started at the base and finished at the nose, approximately 1/32 in. being removed. When the cut is completed, a stop on the feed screw is tripped and the feed stopped. A feature of this machine is that the saddle only is moved to place the tool in position to start the cut. The cross slide is not moved in and out, as is usually the case.

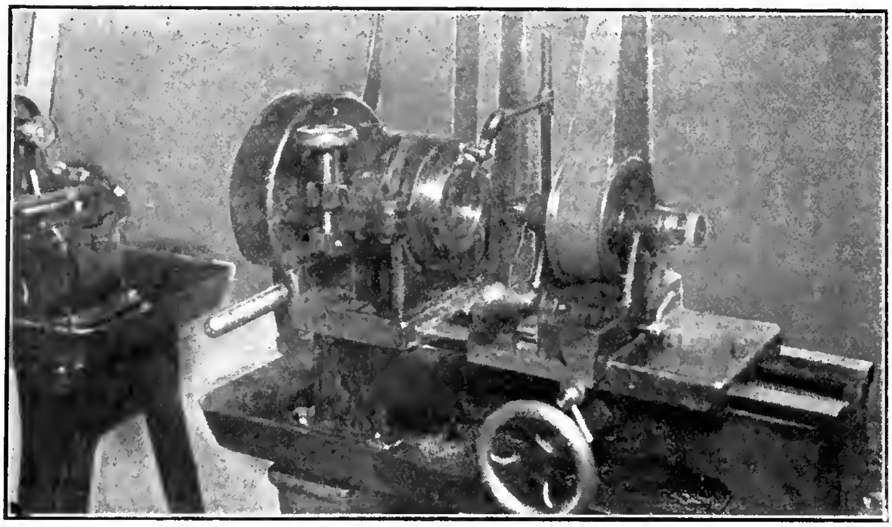


FINISH TURNING RECESS IN BASE.

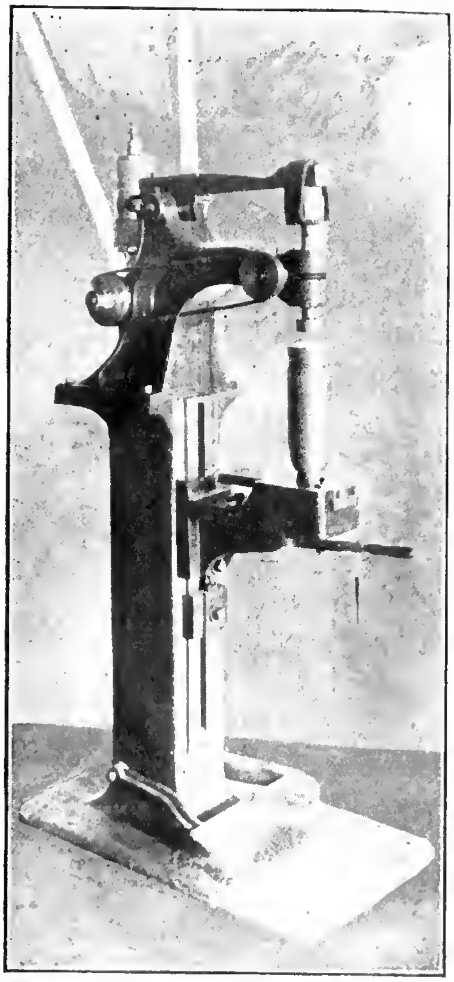
Finishing Base.

At the next operation the base is finished and prepared for threading. Two

engine lathes are installed for this work, supplied by the R. K. Le Blond Machine Tool Co. and by the Fay & Scott Co. The shell is held in a universal chuck, the jaws gripping inside the nose, while at the base end is a steady rest. The base counterbore is prepared for the threads at the next operation and the bottom of base is finished.



MILLER FOR THREADING BASE RECESS, AND FOR THREADING AND FORMING RECESS IN NOSE.



PEINING HAMMER FOR BASE PLUG.

Milling Threads in Nose and Base, Cutting Recess in Base.

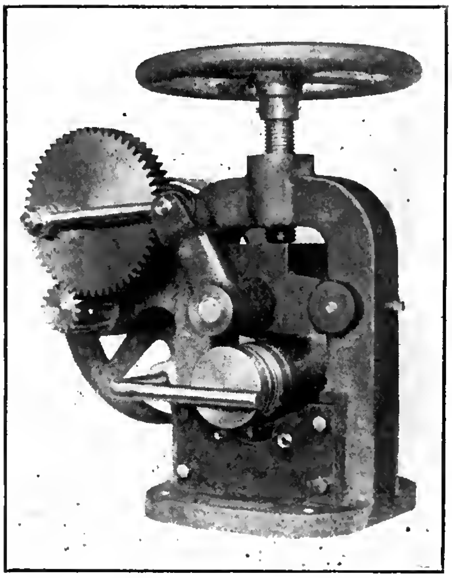
These three operations are distinct, but are performed on the same type of machine. The method of procedure is so very similar in all cases that with few exceptions one description will cover all three. The practice followed at this plant consists of milling the threads, a method which seems well adapted for this particular class of work. The machines installed for this operation were designed and built by the Holden-Morgan Co., Ltd., Toronto, and specially for working on high explosive shells. Results show an accurate and clean thread, with the elimination of the possibility of stripping same. The illustration gives a general idea of the machine and a description covering the threading of the hose will serve to explain roughly the construction and operation of the machine as well.

The casing on the left contains a hollow revolving spindle for holding the shell, while the inside end of spindle is cone-shaped to take the nose. The spindle is thus self-centering. At the end on the left is a worm wheel for revolving the spindle, this being operated by a worm shown below. At the end of the worm, at the back, is a pulley driven from the shafting above. The outside of the spindle is threaded at the centre, and the clamp shown there is closed over the thread when the spindle is required to travel horizontally. At the extreme left and outside of the casting and forming part of the spindle is a flange for operating an automatic stop motion. There is also at the same point a lever for throwing the stop out by hand, if necessary.

The shell is placed in the spindle from the left-hand side, nose first, and a lock-nut with right-hand threads is screwed in the end of the spindle to hold shell firm inside. The milling cutter at the end of the spindle carrying the pulley is inserted in the nose as far as the recess. The pulley bracket is attached to the cross slide on the saddle, which is operated by the hand wheel at the front. When the cutter is inside the nose, the operator, by means of the small lever in front, moves the cross slide up to a graduated stop at the back and locks it. This gives the required depth of cut for the threads. The spindle containing the shell now begins to revolve slowly and at the same time travel in a horizontal direction outwards and thus away from the cutter, which has no lateral motion. The spindle makes one revolution, at the end of which the flange on the outside throws out the automatic stop. The threads are now cut and the shell removed.

When cutting the recess in the base, which is the next operation, the shell is put into the hollow spindle, base end first, and tightened up. As the spindle in this case must not travel, but only revolve, the clamp is removed so that the threads have nothing to work against. A stop is placed in position to prevent the spindle making any lateral motion. Two thin cutters are mounted on the spindle the required distance apart and the spindle inserted in the base. The operation of the slide rest is the same as described above. The spindle makes one revolution as before, and both recesses are cut at one time.

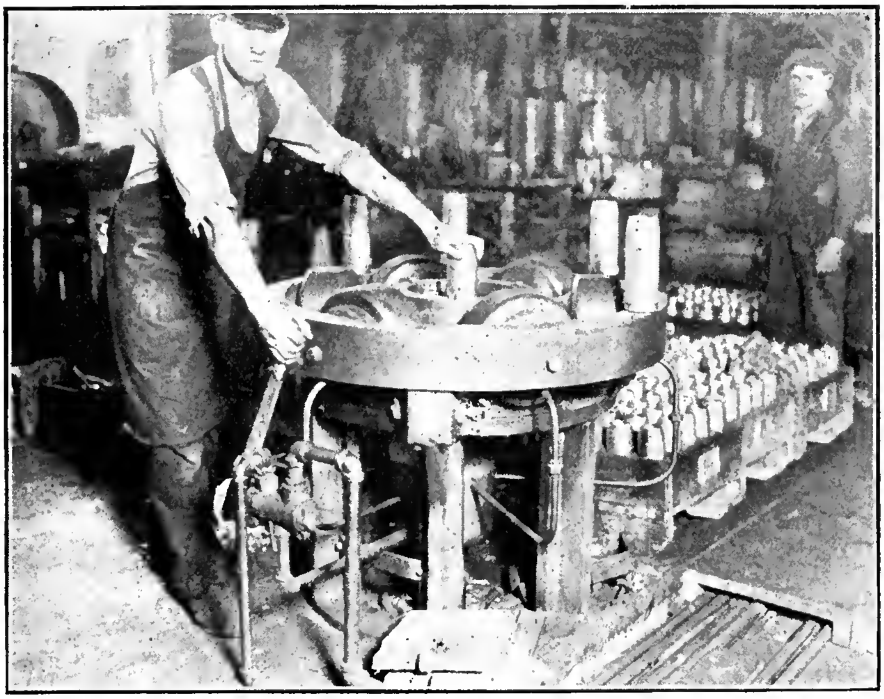
For threading the base, the shell is re-



HOLDEN-MORGAN SHELL MARKING MACHINE.

moved to another machine of the same type, the operation in this case being practically the same as for threading the nose. The principal exceptions are the lock-nut, which has a left-hand thread and the cutter, which is, of course, somewhat narrower. The threads in the base are left-hand, and the machine

operates in the opposite direction to the nose-threading machine. This is taken care of by crossing the belts.



GOLDIE & McCULLOCH BANDING PRESS IN OPERATION.

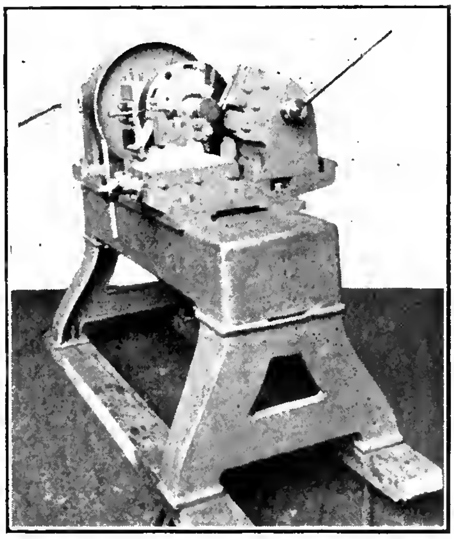
Marking.

The markings are put on the shell by a machine built for this purpose by the Holden-Morgan Co., Toronto. As will be seen from the illustration, the shell is laid on two rollers horizontally against a stop. The operator by turning the hand wheel forces down a round steel die, on which the markings are embossed, on to the shell. The die is oscillated by means of the crank, and has a travel of about 1½ ins., which takes care of the curvature of the shell. The rollers on which the shell rests allow it to oscillate with the die. The machine is continuous running, and rests on a bench when in operation. The markings are the same as for the shrapnel shell, with the exception of mark II. instead of mark III.

Machining Base Plug.

The base plug is a steel forging and, of course, has to be machined and threaded to fit the base. An engine lathe, furnished by the American Tool Works Co., Cincinnati, Ohio, is installed for this purpose. The principal feature about this machine is the construction of the saddle and fixtures mounted thereon. A tool holder with three tools is mounted on the saddle in front, on the cross slide. The square end of plug is held in an expanding chuck tightened up by means of a draw-back mechanism in the headstock. The tools mentioned above rough turn the side of plug, form the camber on the face, and round off the corner in the order mentioned. At the back is a block holding a tool, which finish turns the side of plug.

For cutting the threads on the plug, there is fastened to the saddle at the back a bracket holding a swinging arm. This arm holds a milling cutter operated through a chain drive from a belt-driven pulley on a similar bracket, also at the back. The arm is brought forward and the end clamped to a block on the front of the saddle. The plug revolves slowly, and the cutter, also revolving, cuts the threads, which are left-hand. This firm is developing a special tool for machining and milling the base plug at one chucking.

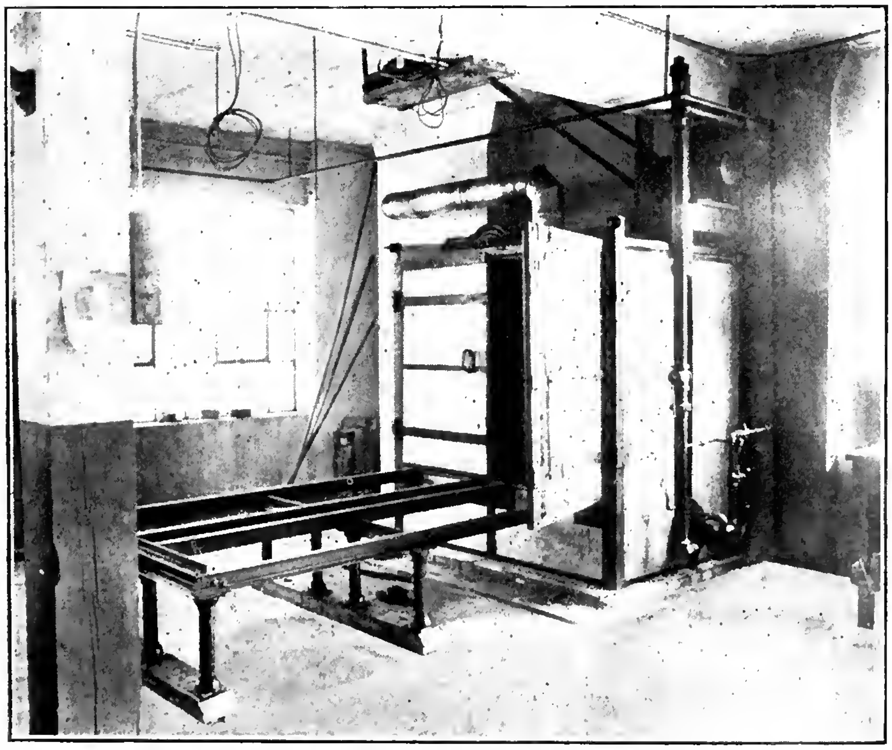


JENCKES MACHINE CO. BAND TURNING LATHE.

Grub Screw Hole and Inspection.

The hole is now drilled and tapped for the grub screw in the nose. The grub screw purpose is to secure the fuse plug. Three high-speed, single spindle, drill presses, supplied by the W. F. & John Barnes Co., Rockford, Ill., are installed for this operation, one drill being equipped with a tapping attachment for threading the hole.

The shells are at this stage gauged and examined by a Government inspector previous to the base plug being screwed in. Before being examined, however, they are taken to a power press to have a series of notches stamped in



EXTERIOR VIEW OF VARNISH BAKING OVEN.

the wave lines. This is an extra safeguard against any possibility of the copper band moving round when the shell is being discharged from the gun.

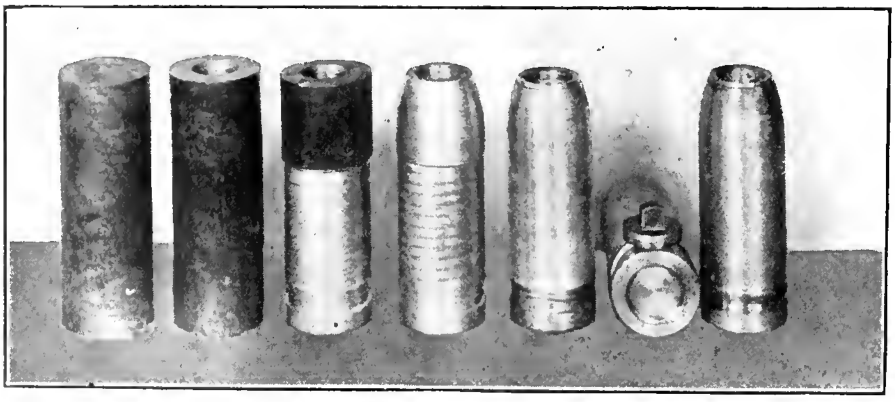
Fitting Plug in Base.

The next stage involves practically four operations, which may be classified as follows: Screwing in base plug, cutting square end off plug. Care has to be exercised in screwing in the plug, as it must come up against the inside of base and be a tight fit. A vertical hydraulic press is installed, which was built by Perrin & Co., Toronto. The shell is held in a horizontal direction in the press by means of a clamp fixture located above the ram. In direct line with the centre of the clamp is a bracket for holding a bar, one end of which has a socket for holding the end of plug, while at the outside end is fixed a ratchet for the base. The plug before being screwed in is covered with a mixture of tar, shellac and rubber cement. The shell is next moved to a "Racine" power hack saw to have the square end of plug cut off, after which the joint between plug and base is hammered.

For this operation a high-speed hammer is installed, being built by the High-Speed Hammer Co., Rochester, N.Y. The illustration shows the principal features of this hammer, and method of operation will be readily understood. The shell is placed over a vertical spindle on the table slide, and is a sliding fit, the slide having first been drawn out to allow for this. This slide is then pushed back and locked, the shell being placed under the hammer, which is operated by a friction pulley and controlled by the operator by means of a foot lever. The hammer head is circular and about the same diameter as the plug. On the face of the hammer head are two small projections or lugs which strike on the joint between the plug and base, thus closing it up. While in operation, the hammer spindle is revolved by means of a worm and wheel device on the head driven by a pulley from the back shaft, thus distributing the blows evenly. The blows of the hammer are of an elastic character, which is obtained by two rubber bumpers in the rear of the machine and a bumper between hammer head and helve. The hickory helve absorbs the shock of the rebound. The base is now turned upon an ordinary engine lathe, which finishes that part of the shell.



VARIOUS STAGES OF MANUFACTURE FROM BAR STOCK TO FINISHED SHELL CASE.

Copper Band Press.

The shells have the copper band pressed on next, and for this purpose are taken to a hydraulic banding press which was built by the Goldie & McCulloch Co., Galt, Ont. The press which is operated by a hydraulic pump, has six horizontal rams 8 in. diameter converging towards the centre and their dies running in guides. The copper band is slipped over the end of the shell into the groove and secured in place with the assistance of a hand hammer. The operator places the shell base down on the plate in the centre and applies the pressure by means of a lever. The six jaws converging closely press the copper band, completely filling the groove and the undercut. The jaws are then released and the shell turned slightly, after which the pressure is again applied thus equalizing same all round the band.

Copper Band Turning.

The next operation consists of turning the copper band. This is performed on a machine built by the Jenckes Machine Co., Sherbrooke, Que., and was specially designed for this class of work. On the headstock spindle is mounted a clutch pulley, the clutch being operated by a lever within reach of the operator. A universal chuck is attached to the spindle and a tool-slide base is clamped to the lathe bed. The shell is placed in the chuck and is located in the correct position by a swinging finger on the front tool block before the chuck is tightened.

The front or roughing tool is held in a fixture working on a cross-slide on the fixed saddle. The tool is fed in by a screw and hand wheel to a dead stop. The front tool holder is also provided with a hinged scraper rest for removing

the ragged edge at each side of band after tooling.

The rear or finishing tool is held in a steel block working in a slide on a fixture on the saddle at the back. The tool is mounted above the work but can be adjusted to pass down behind the shells, and, in passing, shave the band to size. The feed is by lever and pinion.

Varnishing.

The shells are now washed in a tank containing hot soda water to remove the oil, etc, the soda water being heated by means of gas burners located under the tank. The shells dry quickly and are then taken to the varnishing department. The "copal" varnish used is a special preparation for coating the inside of the shell to prevent the explosive from corroding the metal and so weakening the walls of the shell. Lyddite has this peculiar characteristic which of course has to be guarded against. A hollow brass plug is first screwed into the nose to prevent the varnish from touching the threads. The shell is then filled with varnish by means of a "Bowser" self measuring storage tank equipped with a hand pump. The varnish is afterwards poured back into the tank and the shells are placed on a draining rack, nose down, where they remain for an hour or so. The draining rack consists of a wooden framework with a number of sections each large enough for one shell. The shells rest on strong steel netting, under which is a tray for catching the varnish drainings.

Baking.

In order to thoroughly dry the varnish, it is necessary to heat the shells in an oven for a certain length of time at a suitable temperature. This process is known as "baking," and it is done in a "Crawford" sectional gas heated oven supplied by the Oven Equipment & Mfg. Co., New Haven, Conn. The accompanying illustration shows the oven exterior and tracks, but the trucks which are used in connection with it were unavoidably omitted from the photograph. The outside of the oven is constructed of galvanized sheets and the inside of black sheets with insulating material between them to prevent radiation of heat. The doors are also insulated and are a tight fit when closed.

In the bottom section of the oven is a steel cylinder with six pipes on each side, each having a burner at the end, operating on the "Bunsen" principle. In connection with the gas pipes there is also an air pipe conveying air to the burners from the motor driven blower on the top of the oven. The pipe outside on the left is the air pipe with a pressure gauge, and in the middle is the gas pipe connecting to the cylinder head outside of the oven. A thermometer at the side near the top indicates the temperature inside. The shells are baked for eight hours at a temperature of 300 degrees F.

To facilitate the handling of the shells from the draining table to the oven, an overhead runway system is installed. The shells are placed in boxes, partitioned off to hold a batch of 120, and these boxes are slung from the runway, moved along to the oven and deposited on the trucks outside on the tracks. When a sufficient number of boxes have been placed on the trucks they are moved into the oven, the tracks of course extending inside.

Painting and Inspection.

After the baking process has been completed, the hollow brass plugs are removed from the nose and a solid brass plug screwed in. The shells are then carefully examined, weighed and gauged all over by a Government inspector, who selects one from each series of 120 for the firing test. The rest are sent forward to the painting department for the final operation. The painting machine is a portable outfit, and consists of a table with a cup-shaped revolving holder driven by a small electric motor. The shells are placed in the holder and painted while revolving. The priming coat is white and the second coat yellow ochre.

Gauging.

Gauging plays a very important part in making shells, as the greatest accuracy has to be obtained in order that the weight of the shell when completed shall be exact to within very fine limits. This precision can only be secured by the exercise of the greatest care at each operation involving the removal of metal. High and low limit gauges are used throughout, and the shells are gauged after each machining operation. In addition, the shells are gauged and examined twice by specially appointed inspectors, as already stated in this article. The accompanying illustration shows a number of typical gauges used ing the work, all being made by the Holden-Morgan Co. The final weight of shell casing is just under 15 pounds, and 1 oz. only is allowed for come-and-go.

For handling the shells between the various operations, "Chapman" transveying and elevating trucks are used. The shells are stored in wooden racks, each holding a series of 120, and these racks are moved around by means of the truck.

Port Arthur, Ont. — The Board of Trade is organizing local manufacturers in an effort to obtain orders for military equipment.

CAST IRON vs. STEEL SHELLS.

THE fact that fragments of presumably cast iron shell cases have recently been picked up on the battlefields in Flanders has had the natural result of raising the question as to why, if the Germans employ this material, then shouldn't we? The subject has been aired in the British House of Commons, and has formed the theme of more or less correspondence in the editorial columns of both the lay and technical press. Our contemporary, "The Engineer," has very opportunely investigated the matter, and additional point is given to its editorial pronouncement from the fact that it had for inspection a piece of a German cast iron projectile, received from a correspondent.

Referring, in the first instance, to the sample submitted, which was about 2 inches square and ¾-inch thick, the opinion is expressed that it belonged to a 6-inch diameter shell, that the internal surface had been cast on a chill, and that while the outside surface had been turned, the inside had not been so treated. The observations made and deductions drawn, which follow, will be found highly interesting and instructive as well.

Objections.

"There are several objections to such shells. In the first place, where shrapnel is concerned, the number of bullets is reduced because the walls of the projectile must be made much thicker. In the case of high-explosive shell, this does not apply in so great a degree, because the walls of the steel shell are then made thicker than is necessary for strength, but there is such danger of a cast iron shell developing cracks during manufacture that high explosives cannot safely be used in them. It must be remembered that no risk of a shell bursting in a gun must be run, and no one will doubt that there is more risk in cast iron than there is in forged steel.

"Another point against cast iron is connected with accuracy of fire. To ensure this, the projectile must be perfectly in balance. The walls must not only be of exactly the same thickness all round, but they must be homogeneous. At the very high speed of revolution set up by the rifling, a small difference of weight to one side of the centre line would be quite sufficient to cause irregular shooting. With forged steel there is little or no difficulty in securing this balance; with cast iron there is always some danger of local porosity, which, besides being a source of weakness, would destroy accuracy.

"Moreover, if the projectile were cast on a chill core and was not machined internally a risk of the core not being absolutely concentric would always have to

be faced. Accurate fire would then be impossible. To remove a chill core, even if it were collapsible, it would be necessary to have a large hole in the base of a high explosive shell, of which the point is always solid, which subsequently would have to be plugged. If a sand core were used it might be removed through a smaller hole, but the machining of the interior would be difficult owing to the shape of the ogival head and the smallness of the hole through which the tool must be entered. In the case of shrapnel the boring would be much easier, because a large opening is left for filling purposes, but, owing to the small number of bullets that could be carried, cast iron shrapnel cannot be considered.

"All these facts have militated against cast iron shell, and although, of course, cast iron and cast steel were used at one time they have entirely given place to forged steel. Furthermore the methods of manufacture of steel shell have been so developed that such shell can actually be turned out more quickly than those of cast iron of equal reliability and accuracy. An 18-pounder shell for example, can be completely machined from the bar in about forty minutes. The case for the forged steel shell is, then, complete, and there is no case at all for the cast iron shell.

A Case of Necessity.

"The answer is fairly obvious, as to why Germans are using cast iron shells. In spite of the greatness of the supplies of their modern guns and projectiles, the Germans are beginning to find them not inexhaustible under the tremendous drain that is being put upon them. Hence, guns and projectiles have been drawn from stores many years' old to fill up the deficit in modern supplies. The guns use a lower powder pressure, which the cast iron is able to stand, and the shells are probably filled with black powder, so that less danger is to be feared from an accidental burst. We believe this to be the real reason for the fragment of a cast iron shell being found on the battlefield.

"Whether the Allies also are using old guns and shell we cannot say, but it is not inherently improbable. Every nation concerned has been surprised by the part artillery has been called upon to play, and it is not unlikely that all of them have drawn upon resources of every kind that can be turned to account. If the Germans are indeed using cast iron, it is a favorable sign, for it shows that even they, with all their preparation, were unable to collect enough material of a modern kind to meet the requirements of the war.

There are, of course, not wanting those who, while agreeing that for accurate fire or penetration the cast iron shell is non-serviceable, still believe that for scattering earthworks and breaking down wire entanglements, chunks of cast iron are just as effective as chunks of steel, and, of course, cost much less.

A RESULT OF SHELL-MAKING IN CANADA.

APART from the immediate benefits accruing, the growth of the shell business is regarded by many business men as one of the most important developments of its kind that has yet taken place in industrial Canada. Their view is this—that it has shaken a big industry, steel and its allied branches, out of a rut; stimulated inventive qualities in the mills and compelled the development of adaptability to changing conditions.

When the shell business ceases with the end of the war, it is argued that manufacturers will be less ready to throw up their hands, because business along the old lines had ceased, as they did in many cases last summer, and will be alert for new opportunities. The high praise that has been bestowed on the Canadian shell makers by the Imperial Government is proof that adaptability and efficiency of a high order existed, but that initiative was to some extent lacking.

GIVING EXPRESSION TO OUR POTENTIALITY.

The present era in Canada will loom large in the annals of history, not alone because of the part we are taking in fighting for the Empire, but also for the industrial manhood that has been awakened within us. This does not necessarily mean that we are accomplishing great things from a manufacturing viewpoint, but it does mean that day by day we are fast learning, and not without a certain national sense of pride, that we possess a resourcefulness that we knew not of, also adaptive faculties that have been lying dormant and which needed but the inspiration such as present conditions have given us, to awaken our industrial faculties to the point of hitherto non-existent proportions.

AETNA EXPLOSIVES.

ALMOST coincident with the New York report that the Canadian Car & Foundry Co. had placed an order with the Aetna Explosives Co. amounting to about $6,000,000, comes the announcement from Sydney, C.B., that the explosives company was planning to establish a new industry at that place. The details are to the effect that the project has just been organized in New York, and that letters patent have been granted at Ottawa.

This is just another instance of the widespread effect of the shell-making industry in Canada, and there would appear to be every reason to expect that it would be good business for the Aetna Co., after getting an order amounting to $6,000,000, to establish a plant at a point where the business could be expeditiously handled. If Canadian Car & Foundry Co. is going to load shells at Sydney, it would certainly be reasonable that the explosives be made close at hand.

HABIT.

SOURCE of about three-quarters of all human actions, time saver and thought saver, best of slaves and worst of masters—that is Habit. The strength of it is beyond the realization of the people who are the most dependent upon it, and its danger is as great as its value, according to the character of the habits themselves.

A reflective friend of ours has occasion to pass through a certain street every evening at seven o'clock. He says that every night he meets the same people, four or five of them, doing the regular things, so that he looks forward to seeing them, and he is never disappointed.

There is a man who always runs for the seven o'clock car, when he might as easily catch it if he changed his habit of leaving at the last minute to one of leaving the moment before. Then there is the man who drops in regularly at the corner saloon, not because he particularly needs a drink, but because he has done it regularly for some time, and it's easier to do it than stop it. Again, there is a family at dinner he sees as he passes, and the boss is always in his shirt-sleeves, although it is no longer hot weather. You see, he is simply dining with his wife, and he has the habit of doing it this way, and she never gets used to it. She knows better, however, than to try to change his lordship.

Those are some of the habits our reflective friend runs into as he walks through the street nightly. It leads him to make up his mind that if habits are so infernally powerful, how much easier life is to a man who forms them along the right lines. "For," says our friend, "you might as well get the habit of doing it right as of doing it wrong—it's exactly as easy once you get it going. It pays—it's good business, and the habits of punctuality, neatness, courtesy, patience, and a hundred or so more, are so important to life that men call them virtues. However, they are habits, just the same."—Drill Chips.

From Hoisting Engine Manufacture to Lyddite Shells

By F. S. Keith, B.A., Sc.

To take an engineering establishment making a specialty of hoisting engines and convert it into a shell-producing plant in a few weeks with little extra equipment may not warrant a distinguished service medal. It does show, however, that resourcefulness and inventive faculties are being displayed and exercised at this time in a manner which is full of promise for our still greater industrial progress and achievement in the mechanical arts and crafts.

TYPICAL of our machine shops that have changed over to the production of lyddite shells from that of a regular line, is the hoisting engine manufacturing plant here described, and, needless to say, considerable mechanical ingenuity and inventiveness has been displayed in adapting the available machine tool equipment to its new purpose.

Lyddite Shells Less Difficult.

Since the work involved in turning out a lyddite shell involves fewer operations and requires less extra apparatus and detail than is necessary in making shrapnel shells, it seems reasonable to expect that the production of these in Canada should obtain large proportions. In fact, the Shell Committee's specifications for turning out lyddite shells from a solid steel billet is a straight machine shop proposition, except the interior varnishing, baking same and painting, and opens up a wide field for machine shops not now engaged along that line.

Coincident with a description of the various operations necessary to turning out an 18-pdr. lyddite shell, the article will describe the methods adopted in this particular shop to make the greatest possible use of the tools on hand.

Process of Manufacture.

To commence with, the billets intended for lyddite shells are solid steel cylinders, 9¾ inches long by 3½ inches in diameter and weighing 27 pounds each.

The first operation consists in boring ou the billets. This is done on two ordinary drill presses, Fig. 1, Plate I. In the first press, after locating the billet in a jig on the platform, a cap-jig is placed over the top and a small hole drilled about three-quarters of its length. The billet is then placed in the larger drill and a 1¾-in. hole drilled to the same depth as the other. To make this possible on the larger drill, it was necessary to cut three extra slots in the rack to give the proper amount of clearance. The cap-jig used on the first drill was made by Marsh & Henthorn, Belleville, Ont.

Out of the Scrap Heap.

The second operation in the production of the shell consists in nosing and rough-shaping the outside. Ordinarily this is done in a lathe, but by exercising his inventive faculties the superintendent requisitioned an old drill that had long been out of use and converted it into a miller. By this means the work is done much more rapidly than is possible on a lathe, and by using a special tool, which was also manufactured by Marsh & Henthorn, an inexperienced apprentice can operate this machine quickly and effectively. The milling head for this is shown in the illustration on next page. The cutter is arranged so as to take care of the curvature and shape desired. Through the centre of

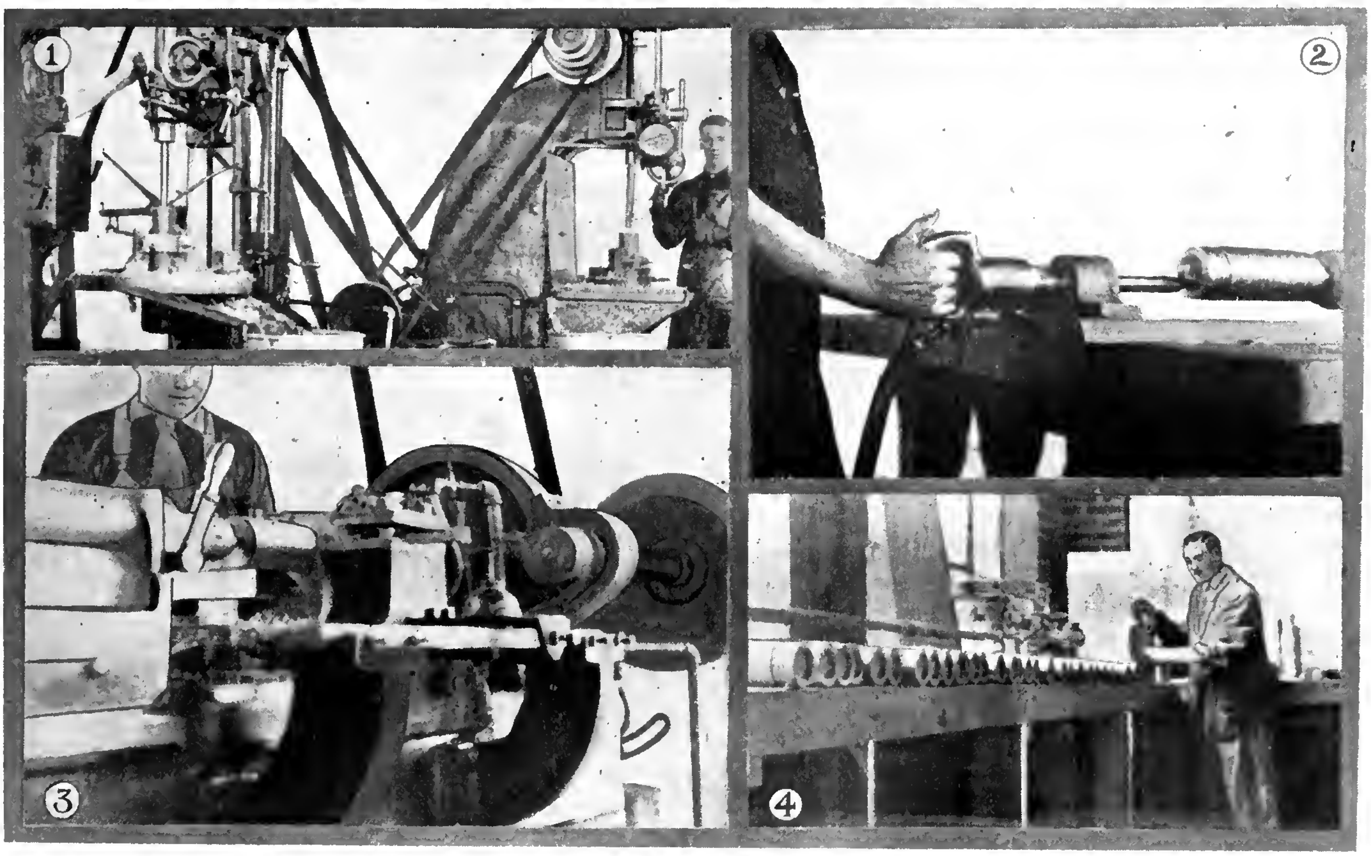


PLATE I.—(1)—BORING OUT BILLETS ON DRILL PRESSES. (2)—PEINING PLUG IN BASE OF SHELL WITH PNEUMATIC HAMMER. (3)—FINISHING SHELL BODY OUTSIDE AND ROUGHING OUT BAND GROOVE. (4)—GOVERNMENT INSPECTION DEPARTMENT.

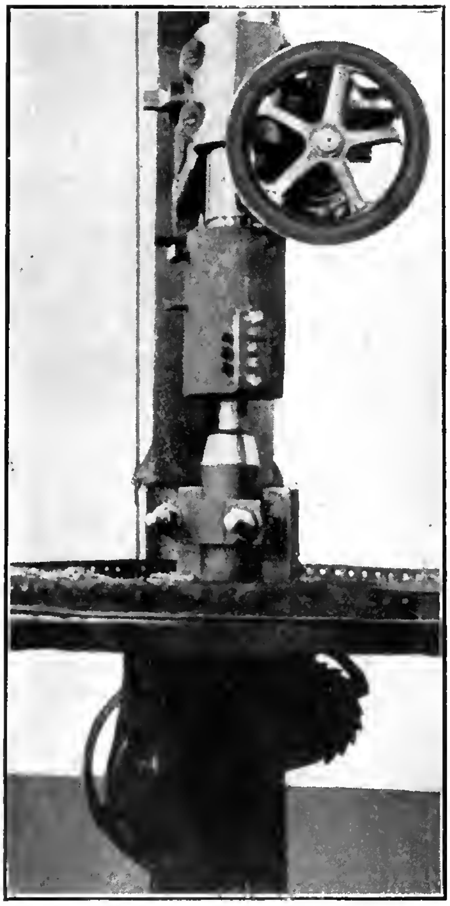
this cutting head is a spindle which fits the already bored hole in the billet, so that any eccentricity occasioned by the drilling is eliminated.

This method was adopted owing to the scarcity of lathes, and it has proven most efficient. When the shell leaves this machine it has been nosed and is faced to the right length.

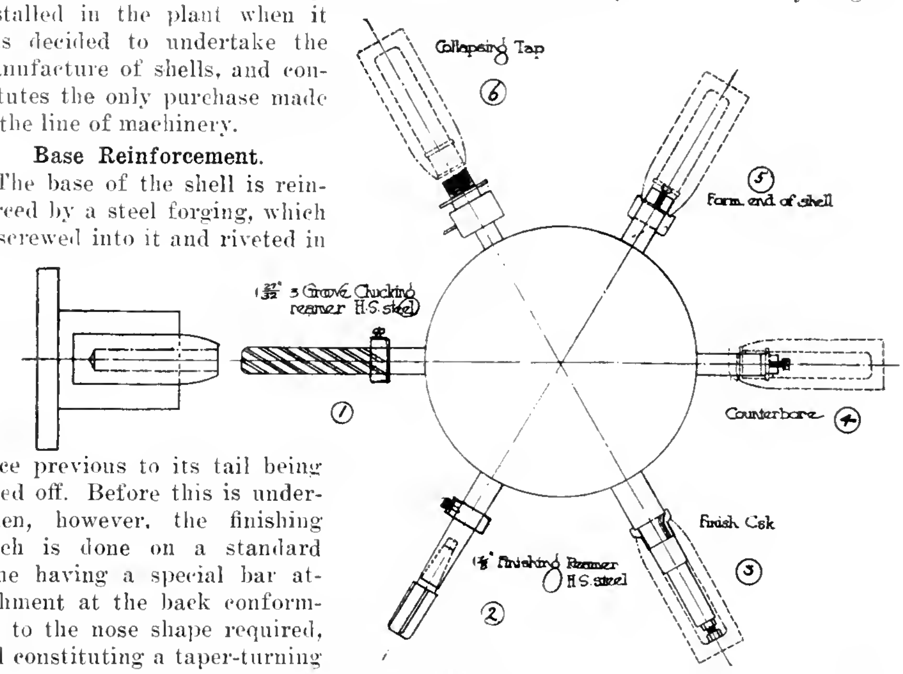
The next operation is that of centering the base, which is done on a special apparatus fitted up on the bed of a nearby engine lathe. This would ordinarily be done on a drill, but by adopting this method it saves keeping a small drill employed for the purpose.

From the centering machine the shell blank is taken to a standard lathe, where it is rough-turned, a forming bar attachment at the back giving the blank the nose shape required. The shell is held at the face plate end in a special three-jaw expanding chuck, and at the other end by the centre on the tailstock.



HEAVY DRILL WITH MILLING ATTACHMENT FOR FORMING SHELL NOSE.

The next move in the process of turning out the completed shell is through a Jones & Lamson lathe fitted with a six-tool turret, as shown in the diagram, above. Here the shell is placed in a special chuck. The first tool is run down, leaving 1/32 of an inch for the finishing reamer number two. Number three tool counterbores the end for the tap and also countersinks the end, while by means of the sliding head on the lathe, number four tool forms the recess at the bottom of the hole for the thread, and number five tool forms the bevel at the outside of the end of the nose. Tool number six taps the thread with a collapsible tap. These six operations absolutely finish the inside machining of the shell. This lathe was the only one not installed in the plant when it was decided to undertake the manufacture of shells, and constitutes the only purchase made in the line of machinery.



TOOLING, JONES & LAMSON TURRET LATHE.

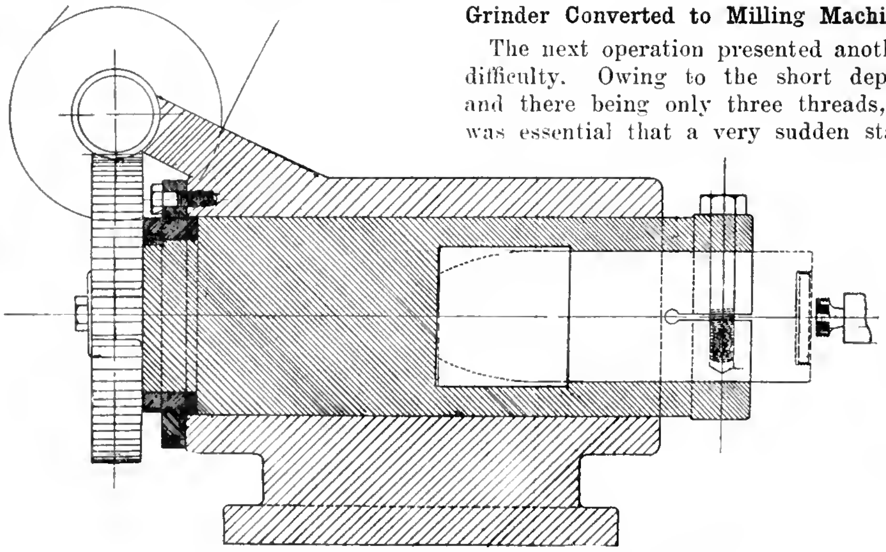
Base Reinforcement.

The base of the shell is reinforced by a steel forging, which is screwed into it and riveted in place previous to its tail being faced off. Before this is undertaken, however, the finishing touch is done on a standard lathe having a special bar attachment at the back conforming to the nose shape required, and constituting a taper-turning attachment. One of the illustrations show this lathe in operation. The wave groove is also made at this time.

To accomplish the reinforcing of the base, a few problems were met with, owing to the lack of another turret lathe, but most of them were overcome in a simple manner. A turret attachment was secured and incorporated on a London Machine Tool Co. lathe. This turret has one tool for boring the recess in the base of the shell, and another for reaming it to size before threading. Owing to the shallow depth of this hole, and the fact that a thread had to be made which was to have a clearance at the bottom, it was necessary to recess the base of this hole. Ordinarily this might have been accomplished by means of a sliding head on the turret, but not having such available, the superintendent invented a special tool which does the work admirably. It is shown by diagram and also in Fig. 3, Plate II., the operator being about to bring the recessing tool into action. This tool is so designed that when set by the operator against an adjustable stop, the correct depth and width of undercut are automatically obtained.

Grinder Converted to Milling Machine.

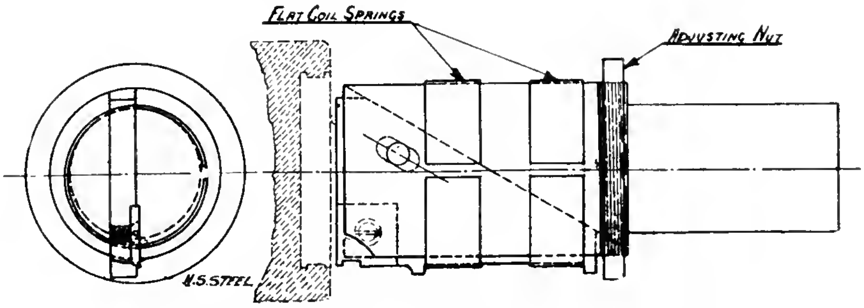
The next operation presented another difficulty. Owing to the short depth, and there being only three threads, it was essential that a very sudden start be made with the thread. This is somewhat difficult to do with a tap; a milling arrangement was, therefore, designed to take care of the threading. Fig. 1, Plate II., indicates just how this was accomplished. As it shows, a universal



THREAD MILLING ATTACHMENT FOR SHELL BASE.

grinder not in use on shell work was converted into a thread-milling device. Same is of particular interest, as it demonstrates what may be done by using a standard machine for special work when ingenuity and resourcefulness are brought into play. It was only necessary to attach a special head, as shown in line cut, this head embodying a large bearing which receives the shell. The bearing being bored and split makes a combination chuck and bearing. On the back end is a master thread of fourteen threads pitch, which works into a nut of the same pitch, so that when the bearing revolves this gives the necessary traverse, as in the case of the lead screw on a lathe. Nearly all parts of this machine were picked up around the shop. For instance, the worm wheel is simply one of the change wheels from a disused standard lathe, while the worm-driving apparatus consists of the driving mechanism which formerly operated the table on the grinder.

After threading, the shell is passed on to a lathe, where the copper band recess waving is done, this being accomplished by means of a cam arrangement on the face plate and already described in connection with the manufacture of shrapnel shells. The last operation before the preliminary test takes place is done on a bench where the shell is secured in a special jig. Here both the top and base threads are cleared of burrs by means of a hand-sizing tap.



H. S. TOOL EQUIPMENT FOR RECESSING SHELL BASE.

Preliminary Test.

The shell is now ready for the preliminary examination, which is practically the same as that for shrapnel shells, consisting of examination for freedom from cracks, flaws, blow-holes, rust and other natural defects, as well as for smoothness of surface. The recess in the base is closely examined also for flaws and gauged for depth and flatness. Notice is also taken that the front thread is cut away to allow extra space for riveting-in the base plate. Every size and measurement is also gauged.

Riveting Base Plate.

After passing the preliminary examination, an important operation is performed. This consists in screwing the base plate into place and riveting it. The base plate consists of a circular disc steel forging with a square head on top. It is first shaped and then threaded with a left-hand thread to conform with the thread in the recess of the base of the shell. After the plate is screwed in place, the shell is mounted on a special jig and by means of a pneumatic hammer, Fig. 2, Plate I., to which a riveting tool is attached, the base plate is riveted securely in place. These base plates have a similar inspection at the same time as

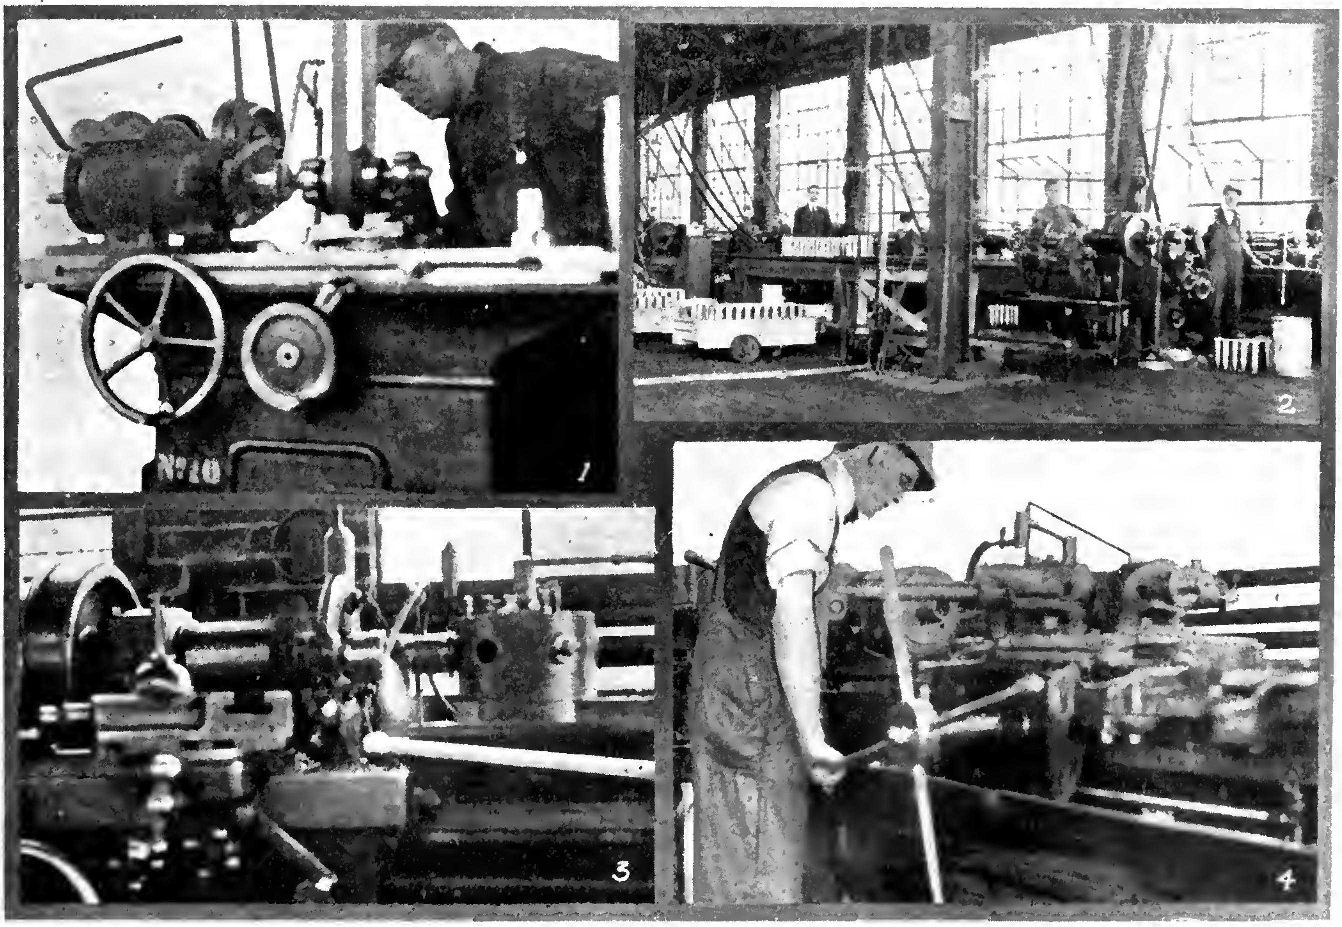


PLATE II.—(1)UNIVERSAL GRINDER CONVERTED INTO THREAD MILLING MACHINE. (2)—GENERAL VIEW OF MACHINE SHOP SHOWING SHELL LATHES. (3)—LONDON MACHINE TOOL CO. LATHE RECESSING SHELL BASE. (4)—JONES & LAMSON TURRET LATHE FINISHING INSIDE OF SHELL.

the shell to guard against physical defects and ensure proper threading and flatness. The head on the base plate is then sawed off, and a hammer test made to ensure the tightness of the plug. A sound test determines whether the plug is loose or not.

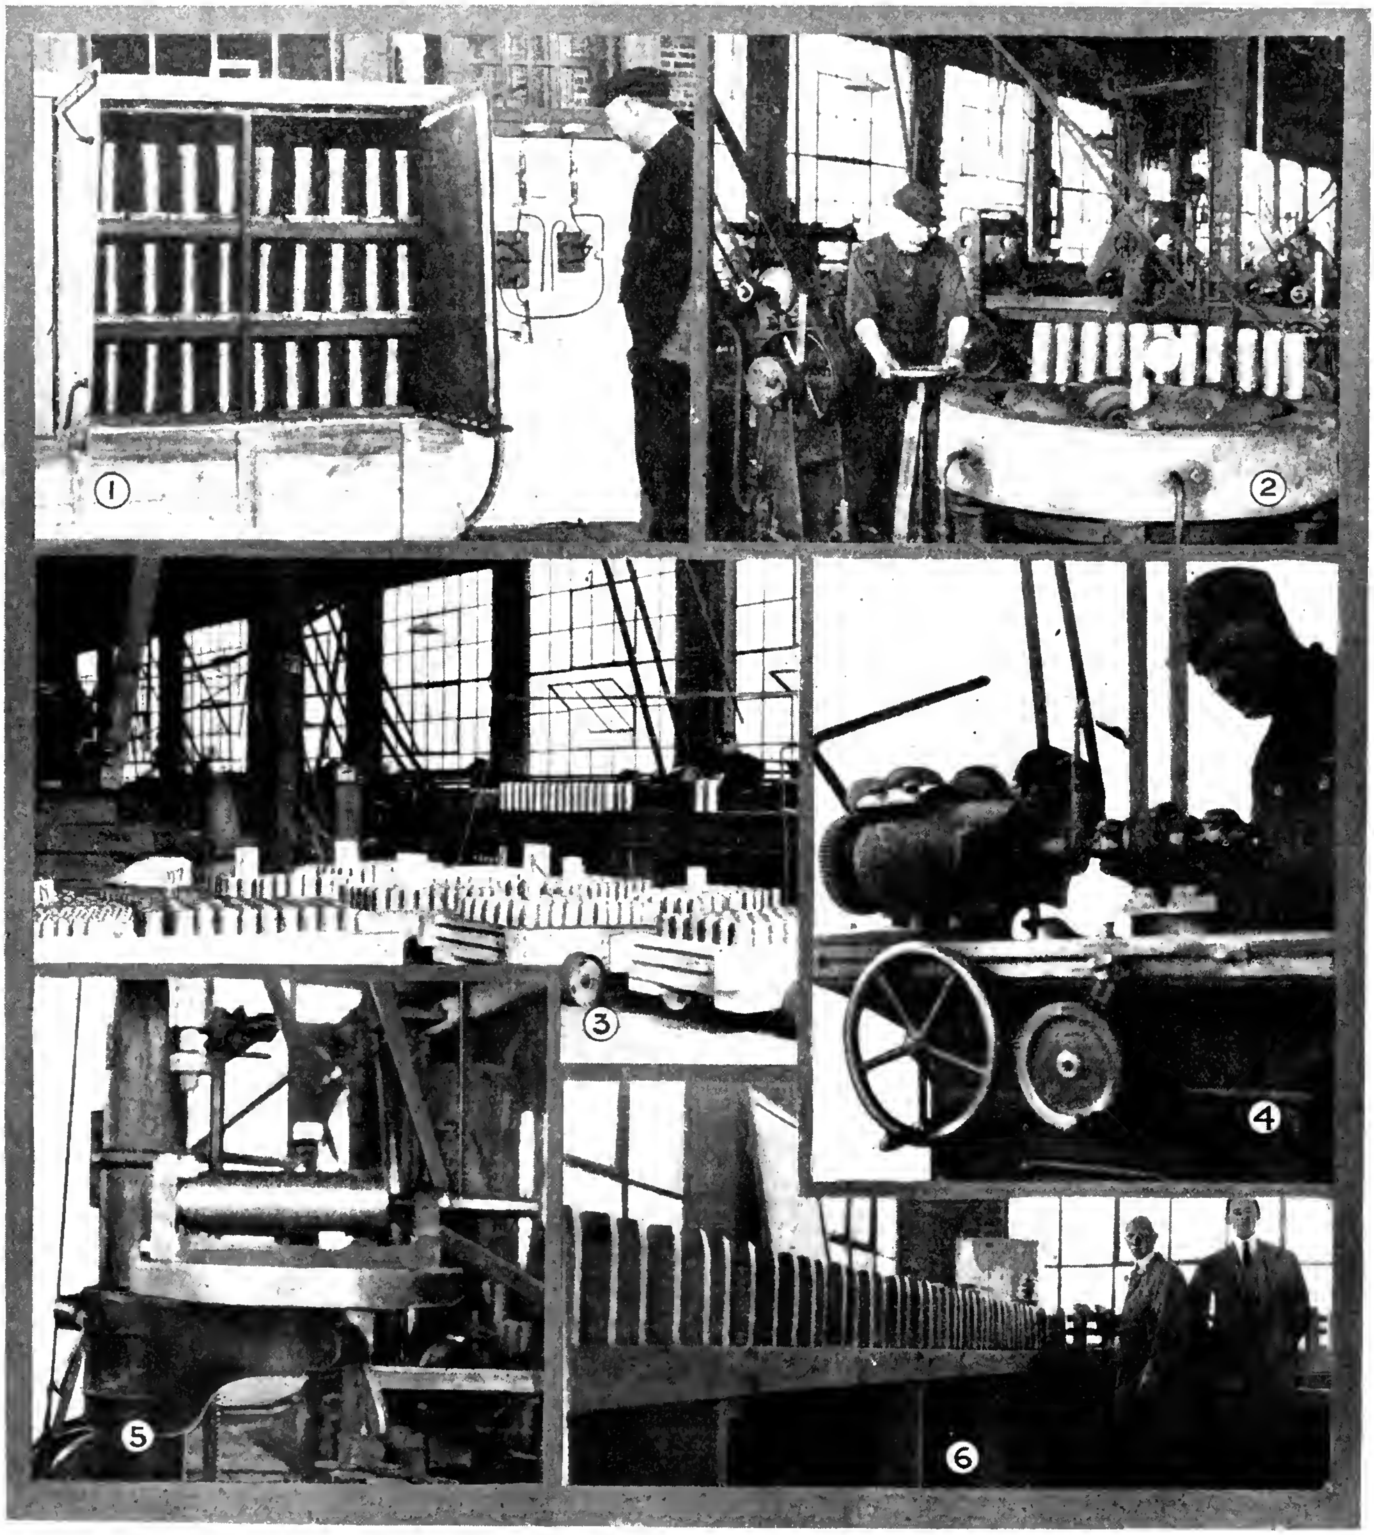

PLATE III.—(1)—ELECTRIC OVEN SHOWING SHELLS IN PROCESS OF BAKING. (2)—MARSH & HENTHORN HYDRAULIC BANDING PRESS. (3) LOTS OF SHELLS READY FOR TESTING. (4)—UNIVERSAL GRINDER CONVERTED INTO THREAD MILLER. (5) SPECIAL JIG WITH SHELL IN PLACE FOR DRILLING GRUB SCREW HOLE. (6) GOVERNMENT INSPECTION DEPARTMENT.

Banding.

An hydraulic banding press, manufactured by Marsh & Henthorn, is next brought into requisition. This is shown in Fig. 2, Plate III. It is of the usual six-cylinder type, having 9-inch rams, and giving 750 pounds pressure. The operation of pressing on the copper band is similar to that for shrapnel shells. When this has been done, the final machining operation is effected. This consists in turning the copper band to size and shape by means of a special tool, and in the same chuck and lathe the finishing face on the end of the shell is accomplished.

Near the top of the nose of the shell a hole is drilled and tapped to hold a small grub screw, which secures the fuse cap in place. This hole is drilled by means of a special jig, Fig. 5, Plate III., placed on the platform of a small drill. The hole is 3/8 of an inch from the top of the

shell, and carries a 13/64 diameter thread. This completes all the mechanical operations necessary.

Final Inspection.

In the final examination, the Government inspector examines and measures with a set of official gauges every part of the shell, and, when found correct, places his initial on it. If found in anywise incorrect and the defect be reparable, the shells are returned to the machine shop, and, following adjustment, are again inspected.

Besides correctness of size, the thread in the top for the fuse must conform with the Government standard. The body gauging is also repeated in the final examination. The copper driving band is examined and tested, gauged for diameter, rib and for seating of cartridge case. A hammer test is given to the driving band, it being tapped with a small hammer to see that there is no looseness.

The length of the shell over all must lie between 9.39 and 9.55 inches, giving a leeway of 16/100 between the longest and shortest lengths allowed. There are 36 separate tests made by the Government inspector on each shell.

Varnishing and Baking.

The varnishing outfit, which was constructed on the premises, consists of a cylinder or container, into which the varnish is poured. The outlet pipe is fitted so as to approach near the bottom of the tank. A small pipe leads from the top of the tank to the compressed air main. The shell is placed over the small outlet pipe and by opening the valve on the air pipe the varnish is caused to flow out at the top of the pipe in the form of a spray, the operation being done instantaneously. The shells when varnished are placed in special shaped castings on the top of a trough, into which the surplus varnish drains, being later returned to the varnish reservoir.

A special electric oven was designed by the plant superintendent and built to accommodate 150 shells in three rows of 50 each. It is arranged for three heats, high, medium and low. The oven operates on a 250-volt, three-phase circuit, and consumes 8 kilowatts per hour. It has the special advantage that one may reach into it and place the shells in their respective places. Eight hours is the baking time allowed for the shells in the oven at a temperature of 300 degrees F. The oven is equipped with a recording thermometer. After varnishing, the shells are painted two coats of yellow ochre, and on leaving the works they must show all inspection marks, physical properties and the series mark, code and heat numbers.

The weight of each shell unpainted is 14 pounds 12¼ ounces, minus or plus 1 ounce, and the painted shell 14 pounds 12½ ounces, minus or plus 1 ounce, which is eight times the leeway allowed in the making of a shrapnel shell. When packed in boxes provided by the Government—six in a box—the shells are ready for shipment.

ELECTRIC OVEN READY TO RECEIVE SHELLS FOR VARNISH BAKING.

SHELL SHIPMENTS.

INSTRUCTIONS, we understand, have been received by the various shell manufacturers in Toronto to hold up their shipments until further notice. The reason is not believed to be due to any notice received from the British War Office, but to the fact that the unfinished shells, which are being manufactured by the various firms throughout the Dominion, are arriving at the explosive factory, where they are being completed, faster than they can be turned into fixed ammunition, ready for shipment to the Old Country.

It is generally believed when Mr. Thomas, representative for Lloyd George, British Minister of Munitions, arrives to make enquiries into the output from this country, that some action may be taken or some suggestion adopted whereby the fixed ammunition problem will be solved and that arrangements will be made whereby Canada will have the facilities for turning out the finished product as quickly as the various manufacturers can turn out the unfinished shell.

THE LONG PULL.

WHY is it that so many customers or potential customers make a practice of demanding a little more capacity than the standard machine provides? For instance, a 2¼ ins. x 36 ins. bar lathe must admit 2⅜ ins. in diameter, or must turn 37 ins. long. A 1¼ ins. diehead must screw 1⅜ ins. A machine swinging 18 ins. will be purchased if it will take an 18½ ins. job and so on.

It does not seem to matter very much what size of machine is in question. Whatever it is it ought to be a little bit more, and the result is that pressure is constantly being put upon designers to make their spindle holes larger, and, therefore, the spindle walls thinner, their centres higher, their beds longer, and so on. It is useless to make the spindle stronger when the hole is increased, as the increased strength immediately prompts a demand for a larger hole still.

If the maker holds his ground and states that his machines will not stand stretching in capacity he is looked upon as obstinate, or as designing too near the limit, or of being ignorant of the strength of his own machines; on the other hand, if he agrees to the stretching process he runs risk of trouble and often renders his machine disproportionate, and, therefore, unsatisfactory in some details. If he permanently alters the design of the machine to make everything right it becomes a larger size than he started with, and so the process goes on, small machines growing into larger ones by passing through a series of periods during which they overgrow their strength.

Every maker of every kind of machine must be familiar with this tendency, but the wise ones are those who decline to play with their factor of safety in the manner indicated by refusing to gratify an unwholesome desire for the "long pull."—Herbert's Monthly Review.

A modern torpedo costs something over $2,000.

Lyddite Shell Production in a Specially Equipped Plant

Staff Article

An installation such as is here described puts the onus of successful production for the most part on the machine tool builder, and, as to how the latter has met the requirement as far as 3.3 high explosive shells are concerned, a careful study of the operation illustrations and text data will make the position clear. It will also evidence the ingenuity of the management.

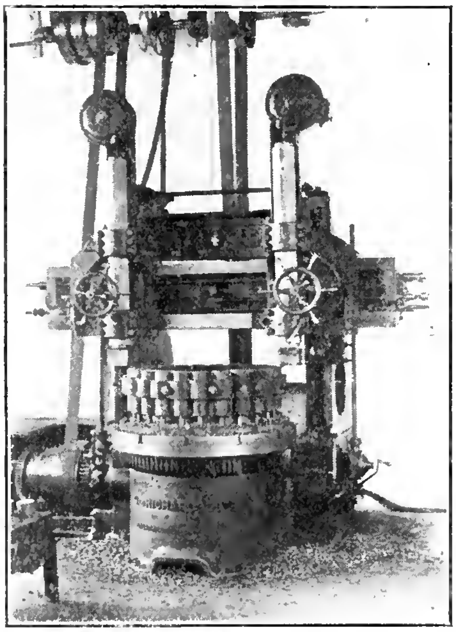
THE manufacture of high explosive shells will possibly arouse more interest in Canadian engineering circles than shrapnel has done. For one reason, the demand promises to be greater. The fact also that they are made for guns of larger calibre as well as for the 18-pdr. weapon lends additional interest. At the present time only 18-pdr. high explosive shells are being made, but 4.5 and 60-pdr. shells are on the tapis for the near future: in fact, preparations are already under way to handle the 4.5 shell.

The explosive used in these shells is lyddite, which corresponds to the French melinite and takes its name from Lydd, in Kent, England, where the British Government first undertook its manufacture. Picric acid is the principal base constituent, and it is one of the most powerful explosives known.

Shrapnel and Lyddite Comparison.

The 18-pdr. lyddite and shrapnel shell vary in many ways, the only feature common to both being the copper-driving band: of course, the outside diameter is the same for both types. From a glance at the line cut on page 1, it will be observed that the shell is parallel and the walls of equal thickness. The closing-in of the nose is dispensed with, the outside of the nose being turned down to the necessary shape. Generally speaking, the manufacture of these shells presents fewer difficulties than shrapnel. No heat treatment is necessary, and, as a consequence, considerable anxiety and trouble is eliminated. Another feature of note is that no forging is necessary, the 18-pdr. high explosive shell being made from a round steel bar 3½ in. diameter, cut approximately to the finished length at the mill.

The machining operations begin at the round steel bar, and are briefly as follows:—Cutting to length on a boring mill to facilitate the work on the automatic machines. The outside of the bar is then rough turned, which includes rough turning the base and counter-boring or recessing the base. The copper band groove is cut and dovetailed, and the wave formed. At the next operation,



TRIMMING H. E. SHELL BARS TO LENGTH.

the remaining half of the bar is rough turned, the nose formed, and the bar rough bored. The bar is next finished inside and the inside of the nose threaded. Following this operation, the outside of body and nose of the shell is finished in a lathe, the base recess finished and threaded, and plug screwed in. After the base has been finished on an engine lathe, the copper band is pressed on and turned up. The shell having been marked, is now ready for varnishing and baking and then painting.

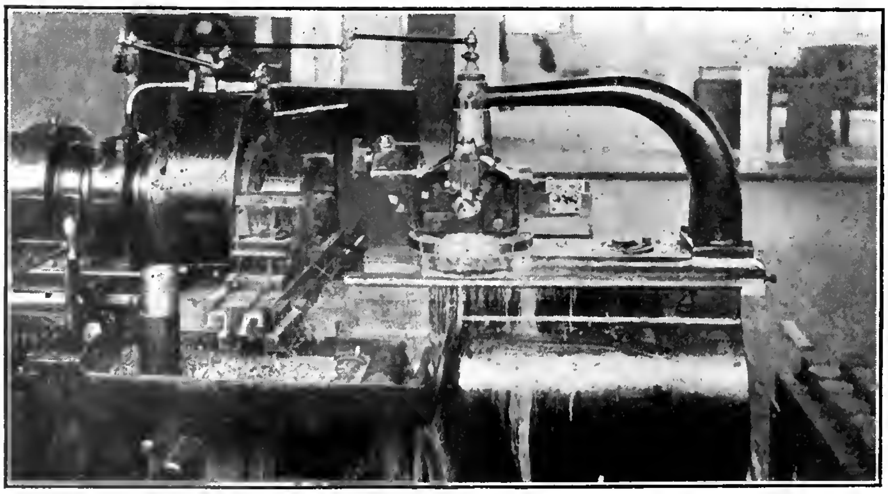
The plant which is the subject of this article was one of the first to engage in the manufacture of 18-pdr. lyddite shells, and the procedure adopted will, therefore, be of special interest. With few exceptions the machine tools and other equipment are new and laid out to suit the order of operations, with a corresponding saving in time and labor. An interesting feature is the installation of several motor-driven automatic machines for the second, third, and fourth operations.

Trimming Bars to Length.

The bars, which are 3½ in. diameter, are shipped from the mill in 9¾-in. lengths, which is rather longer than the finished shell. The ends, of course, are not always perfectly flat and square. To overcome this, and also to cut the bars to the required length, a machining operation is necessary. A vertical boring mill is employed for this work. The mill, which was supplied by George Richards & Co., Manchester, England, has a special casting, fastened to the table, and made to hold 22 bars. Each bar rests on a vertical stop and is clamped to the casting, one clamp holding two bars. The tool, which is set to a gauge, machines the bars to the required length for the next operation.

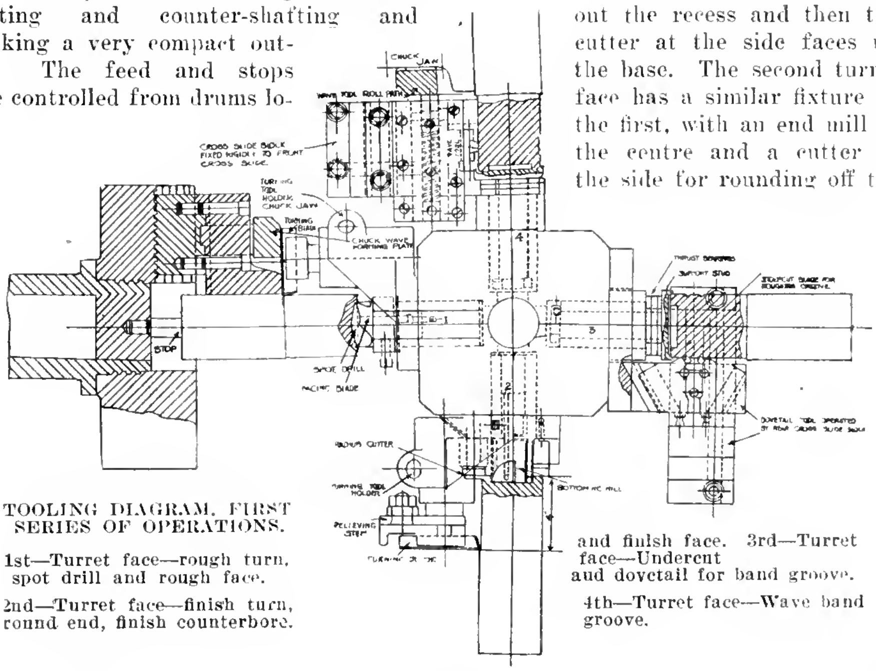
Rough-Turning Shell Body, Recessing Base, Grooving, Dovetailing, and Waving.

A battery of nine No. 6A automatic chucking and turning machines, made by the Potter & Johnston Machine Co., Pawtucket, R.I., is installed for this operation. Each machine is operated by a 5 h.p. C.G.E. induction motor mounted on a motor base and driving through a direct



ROUGH TURNING BODY, RECESSING BASE, GROOVING, DOVETAILING AND WAVING.

gear drive, thus eliminating the usual belting and counter-shafting and making a very compact outfit. The feed and stops are controlled from drums located inside the base of machine. Cutting compound supplied by the Cataract Refining Co., Buffalo, N.Y., is used, and is forced through holes in the drills as well as over the work. Each machine is equipped with a universal chuck on the face of which is attached a three point cam for use in the waving process.



TOOLING DIAGRAM, FIRST SERIES OF OPERATIONS.

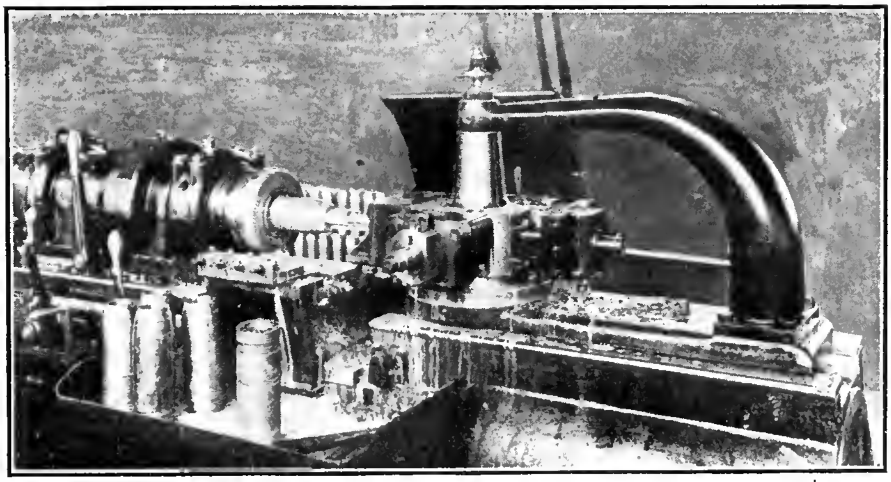
1st—Turret face—rough turn, spot drill and rough face.

2nd—Turret face—finish turn, round end, finish counterbore, and finish face. 3rd—Turret face—Undercut and dovetail for band groove.

4th—Turret face—Wave band groove.

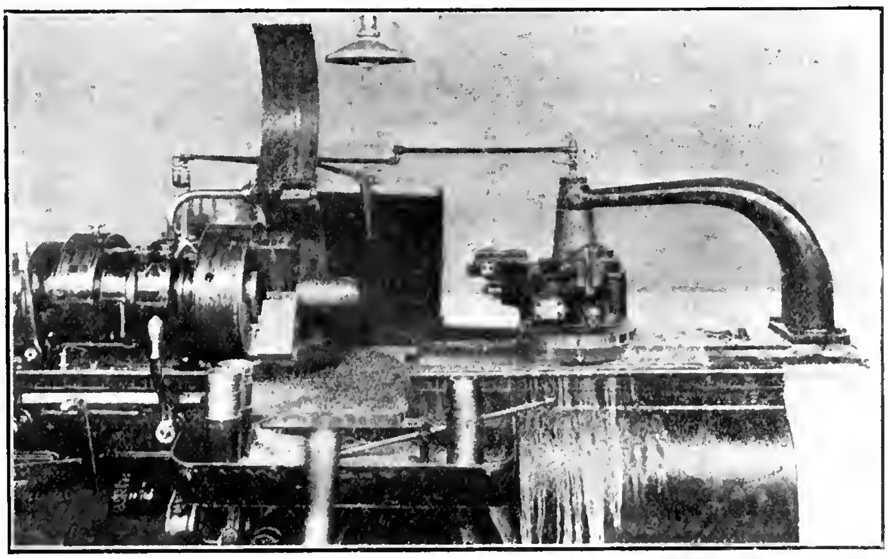
The sequence of operations on these machines is as follows:— Rough-turning outside of bar stock about half its length, machining recess in base, facing-up base and corner, grooving, dovetailing and forming the wave for the copper band. On the first turret face is a bracket fixture, the top part of which overhangs and holds a vertical tool. In the centre is a spot drill and at the side of the drill is a cutter for facing up the base. The turret advances and the vertical tool takes the first roughing cut off the bar. When nearly at the end of the travel, the spot drill roughs out the recess and then the cutter at the side faces up the base. The second turret face has a similar fixture as the first, with an end mill in the centre and a cutter at the side for rounding off the corner of the base. The procedure is the same as in the first case. The vertical tool takes the second cut to within 1/32 of the finished size, while the end mill roughs out the recess in base ready for threading, etc., at a future operation.

The turret now swings round again and presents the third face which has a ball bearing cup centre to hold bar steady, and, at the side, a fixture holding the dovetailing tools. The undercutting tool is held on the rear cross slide block, the tool being under the work. The cross slide is operated by means of a separate cam and drum. The undercutting is done at the same setting as the dovetailing which now follows. The dovetailing fixture, when in operation, is at the far side of the work from the operator. It consists of two small holders each holding a hook nose type of cutter and working in diagonal slides. The cutters are forced in by a push block fastened to top of the cross slide block referred to above. To get the required depth of dovetail, adjusting screws are fitted. Great care must be exercised in setting these tools as the slightest maladjustment may cause the rejection of the shell if the slot is too wide. Sufficient metal is left after undercutting to form the wave which is next cut.



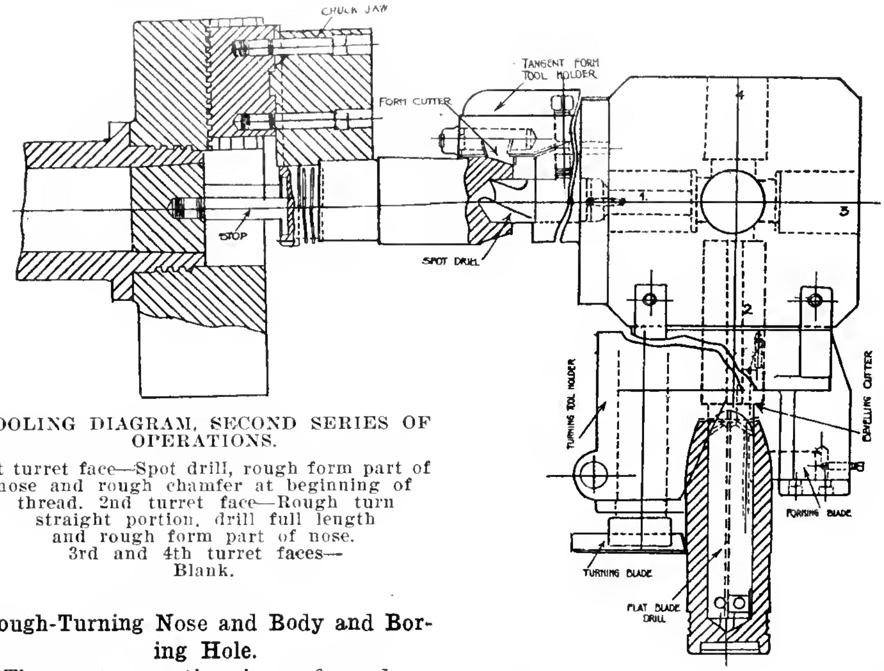
FINISH BORING, THREADING NOSE, FORMING FUSE PLUG SEAT AND RECESS.

The fourth turret face carries a cup-shaped ball bearing centre for holding the shell bar steady during the waving operation. The waving is done by means of a bar sliding in a block fastened to the cross slide, this fixture, of course, being at the side of the work. At the end of the sliding bar is a roller which runs up against the face of the cam fastened to the chuck. This cam is so made as to generate the required form to the wave. The roller is held up against the face of the cam by a spring inserted in the under part of the sliding bar. There is always tension on this spring, and more so when the roller is against the cam face. It is necessary to have a strong spring to ensure a perfect wave on the shell. The cutter is held in the sliding bar and is made with two recesses or



ROUGH BORING, ROUGH TURNING OUTSIDE BODY AND FORMING SHELL NOSE PROFILE.

vces. It is adjustable and set at any angle, and can be taken out, ground and put back without much trouble.



TOOLING DIAGRAM, SECOND SERIES OF OPERATIONS.

1st turret face—Spot drill, rough form part of nose and rough chamfer at beginning of thread. 2nd turret face—Rough turn straight portion, drill full length and rough form part of nose. 3rd and 4th turret faces—Blank.

Rough-Turning Nose and Body and Boring Hole.

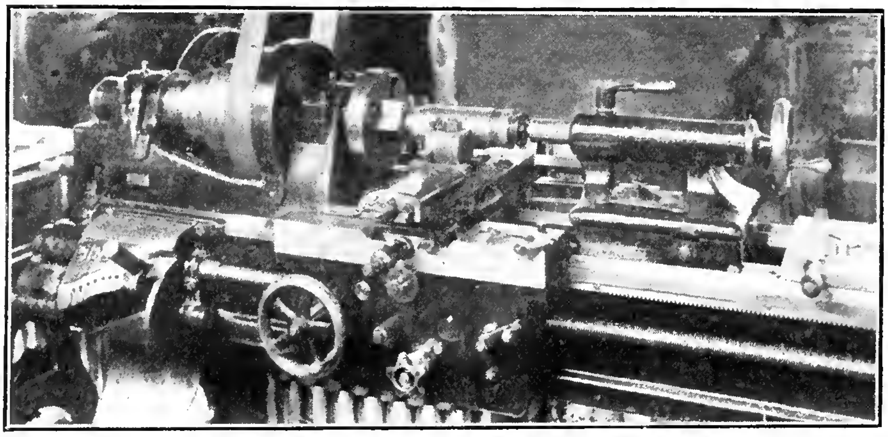
The next operation is performed on a Potter & Johnston motor driven automatic. There are nine of these machines of identically the same type as used for the previous operation except for the tooling. This operation consists of rough-turning the outside of bar—the part not machined at the previous operation, rough-turning or forming the nose, rough-boring the hole and facing up the nose end. The bar is of course solid and square at the end and considerable metal has to be removed at this time.

The first turret face holds a fixture with a spot drill in the centre and a forming cutter in the holder above. This drill enters a short way into the bar preparing the way for the second drill. The cutter at the top forms the front half of the nose curve. The second turret face holds a long cutter in the centre and a fixture with overhanging bracket holds a vertical tool very similar to the one used in the previous operation. At the side of the drill is a holder containing a cutter for forming the second or back half of the nose. While the hole is being bored out, the vertical tool on the fixture is completing the rough turning of the outside of bar. At the base of the boring bar is a small cutter for forming the taper fuse plug seat inside the nose which is done while the drill is finishing the cut.

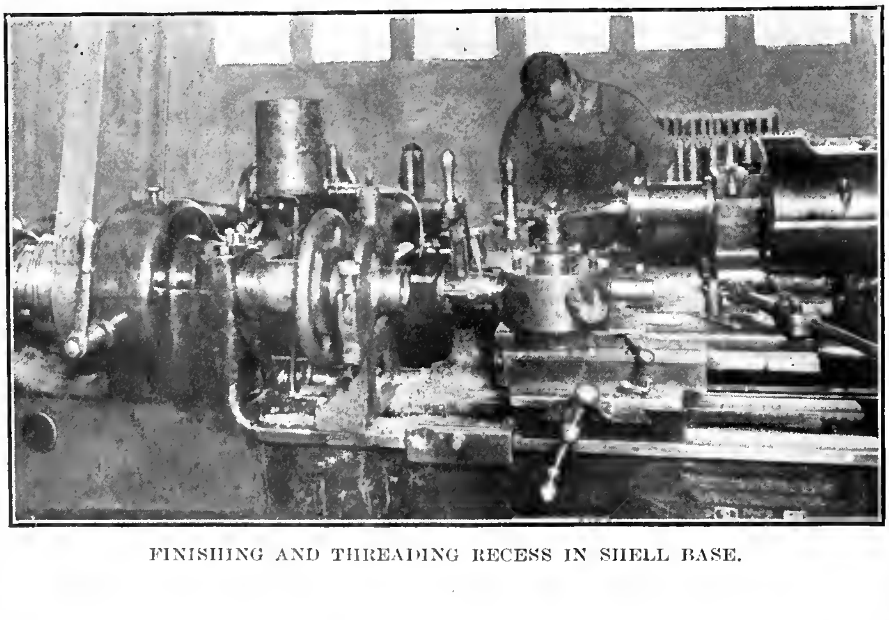
Cutting Recess and Threading Nose.

The next operation consists of finishing the inside of shell, cutting recess in nose, threading same, and cutting shoulder outside at the end of the nose. A battery of six Potter & Johnston automatic machines are employed for this operation. They are the same type as used in the two previous operations except of course for the tooling and also a collet chuck, the latter being operated by a drawback mechanism. The first turret face holds a boring bar which makes the finishing cut inside the shell including the base formation. A single point tool located at the desired position on this boring bar bores the exact diameter for nose threading. At the next setting a tool with two cutters is employed, one of which is for forming the shoulder on the outside of nose and the other for facing up the fuse plug seat. A bar stop on the turret controls the depth of cut.

The third turret face holds a fixture for forming the recess inside the nose at the end of the threaded section about $1\frac{1}{2}$ in. down from the end of nose. This recess is for a clearance space when threading the nose. The fixture consists of a vertical slide which operates a tool holder mounted on the turret face. A suitably shaped cutter is held in a bar in the holder. The turret advances and at a given point the bevelled stop on tool holder engages with a similar shaped stop fixed on the cross slide. This forces the tool up, thereby cutting the recess. At the fourth setting, the nose is threaded by a "Murchey" collapsible die. This operation finishes the inside of the shell.



FINISH TURNING SHELL BODY ON ENGINE LATHE.

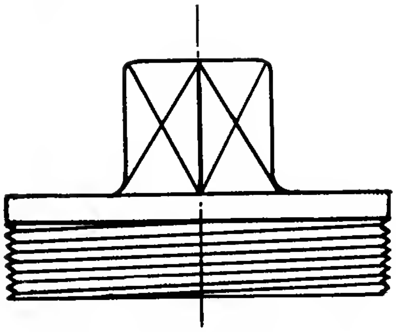


FINISHING AND THREADING RECESS IN SHELL BASE.

Finishing Outside of Shell.

After leaving the automatic machines the shells are taken to a bench and gauged all over. They are then moved to

a lathe for the outside to be finished. An ordinary engine lathe is used for this operation, the lathe being equipped with a face plate having a special driving attachment which engages with the square end of a threaded centre plug screwed into the shell. To insert this centre plug at the nose end, the shell is held in a special bench chuck. For the tailstock end, a centre is used with a taper end for fitting into the recess in base of shell.



FORGED STEEL BASE PLUG.

An ordinary turning tool is used and one cut is taken off the full length of the shell including nose. The cut is about 1/32nd deep and finishes the outside of shell body. To obtain the correct profile for the tool to follow, a special cam attachment is used. The cam is fastened to a bracket attached to the lathe bed at the back, while a fixture attached to the cross slide extends over the cam and has a roller fastened to it which engages with the cam. A weight is attached to the cross slide extension for holding the tool up to the work. Four lathes are so equipped for this operation, being respectively of "Barnes," "Cisco," and "McGregor, Gourlay" makes.

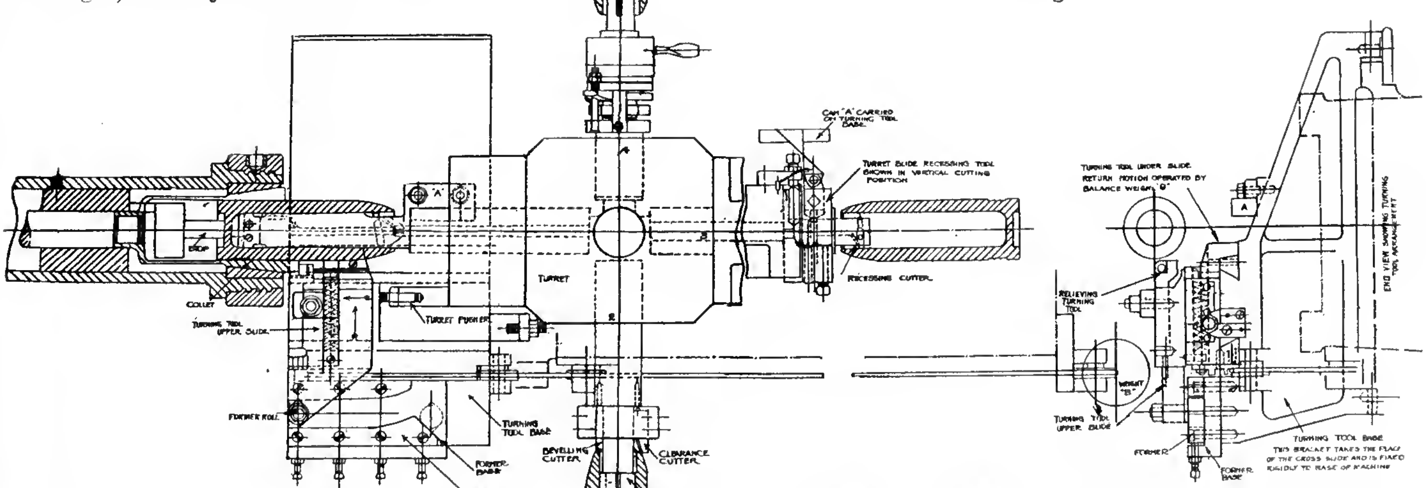
Finishing and Threading Recess in Base.

In addition to the work involved in finishing the base recess a number of minor operations are performed at this stage. After the shells have been turned they are taken to a drill press for the grub screw hole to be drilled. A multiple spindle drill is used for this work. During this operation, the shell is held in a special vise which has an attachment in the form of a jig to ensure that the hole is in the correct position. Alongside the drill is an automatic tapping machine for tapping the grub screw hole. In this case, the shell is also held in a vise with a quick tightening wedge attachment.

The shell is now ready for the recess to be finished. A Warner & Swasey turret lathe is used for this operation. The shell is held in a special chuck and carrier. The first tool bores out the sides of recess, the next tool faces up the base, while the third finishes machining the base and squares up the corners. The fourth turret face holds a collapsible die with left hand threads. The recess is tapped to take a plug which is screwed in at a later operation. The base is next hand-tapped, the shell being held in a special bench chuck for this operation. Careful inspection and gauging of each shell follows, so that any minor defect revealed may possibly be corrected by further machining. For this work a lathe made by the Canada Machinery Corporation is installed.

Fitting Plug in Base.

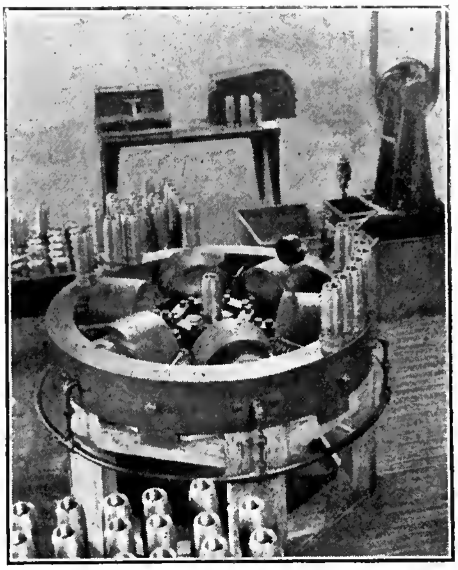
In the manufacture of high explosive shells it is of the greatest importance that there should be no defects and more especially is this so relative to the base. The bar stock is liable to have a "pipe" in it, and the reason for boring out the base and inserting a plug is to overcome this possibility, and at the same time give added strength. If this were not done and any defect did exist there would be a danger of the firing pressure rupturing the base and igniting the explosive, thus destroying the gun, with probable fatal results to the gun team.



TOOLING DIAGRAM THIRD SERIES OF OPERATIONS.

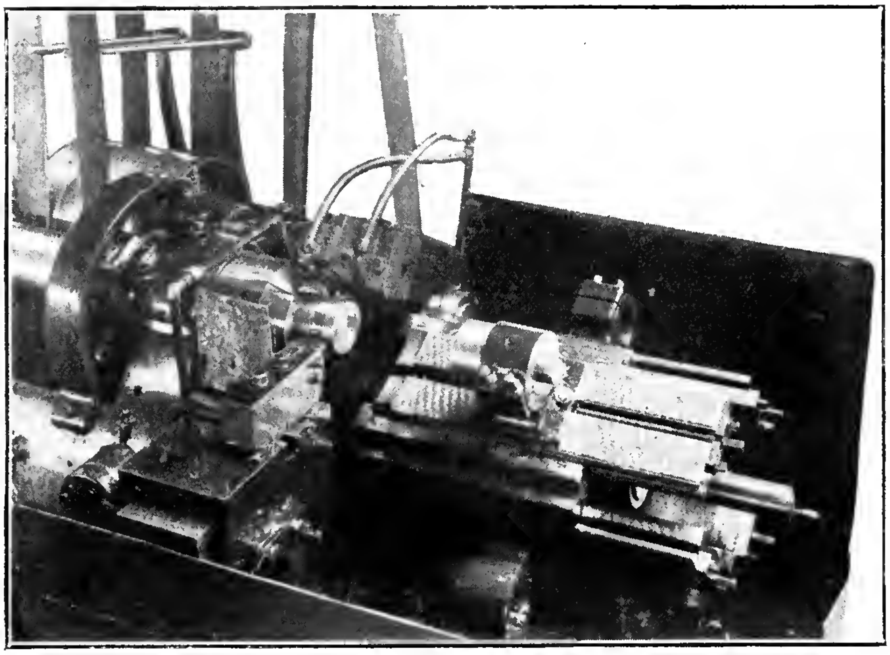
1st turret face—Finish turn with one continuous cut from end of nose to a point to meet finish cut taken in first series of operations. Finish size hole and finish form bottom. Finish bore for thread. 2nd turret face—Finish cut bevel at beginning of thread and form clearance at end of arc. 3rd turret face—Recess for thread. 4th turret face—Tap.

The plug is a homogeneous steel forging, see illustration, faced up, and threaded to suit the counterbore or recess in the base, the threads of course being left hand. The square head is for the tightening wrench and is cut off later. The plugs are machined in a turret lathe supplied by the Seneca Falls Mfg. Co., and involves quite a simple operation. The plugs are screwed in by hand on a bench equipped with box chucks, the threaded portion being covered with a mixture of tar, shellac and rubber cement. They are inserted and tightened up by means of a long handled wrench, and are tapped with a hammer to ensure bottoming.



CANADIAN FAIRBANKS-MORSE BANDING PRESS IN FOREGROUND AND "BERTRAM" MARKING MACHINE IN REAR.

The next operation consists of cutting the square head off the plug, rolling and machining the base. This is performed on an engine lathe with ordinary tools.



COPPER BAND TURNING ON A "GRIDLEY" SINGLE SPINDLE AUTOMATIC.

The lathe has a special chuck and carrier. A parting tool is first put into the holder and the square end cut off. A rolling tool now replaces the parting tool and the joint between the plug and base of shell is closed up. A turning tool is then put into the holder and the base finished up. The shell is now ready for the copper band.

Banding Operation.

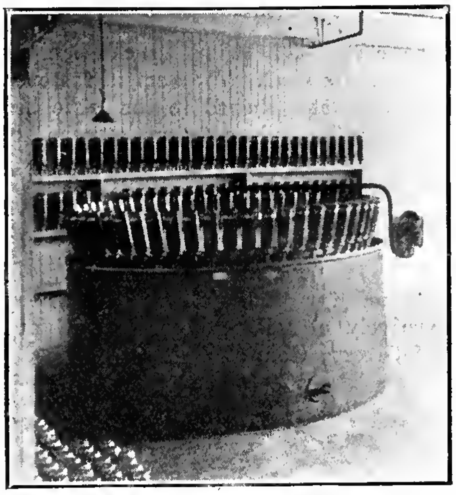
The hydraulic banding press was built by the Canadian Fairbanks-Morse Co., Toronto. It has six cylinders working radially towards the centre and is operated by a belt-driven pump. The copper band is slipped into place on the shell, the latter being then set with its base on a plate in the centre of the machine. Pressure is applied through six rams, working in guides whose ends conform to the shape of the band. After the first pressure application the shell is turned slightly around and the first operation repeated, thus equalizing the pressure on all parts of the band. The rams are returned to their original position by six horizontal springs located between the cylinders. A pressure of approximately 800 tons is applied, a pressure gauge registering the exact amount.

Marking Shells.

The markings on the shells are made by a "Bertram" shell-marking machine, this mechanism having been specially designed for this purpose. As will be seen from the illustration, the shell is placed vertically on the machine, and the die travelling in a horizontal direction draws the shell in between it and the bracket and presses the raised markings on the die into the shell. The machine is belt driven and is continuous running.

Copper Band Turning.

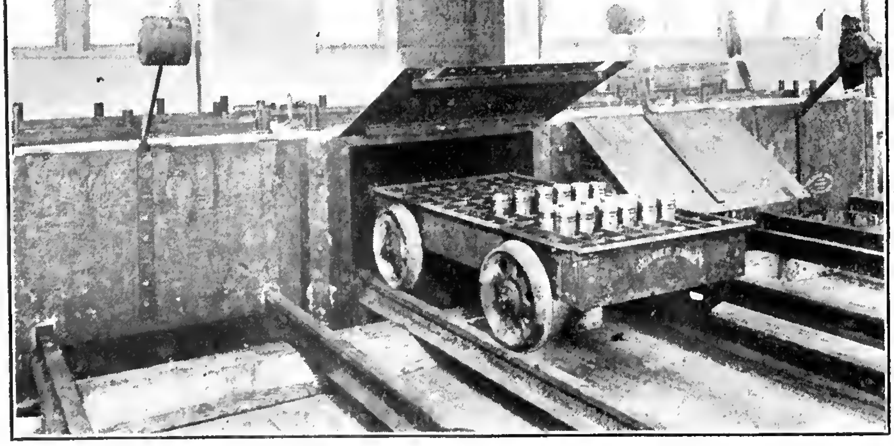
The copper band is turned on a "Gridley" single spindle, automatic machine built by the Windsor Machine Co., Windsor, Vt. The machine is belt driven and is entirely automatic even to tightening the chuck and releasing it at the end of the operation. The chuck is of the collet type usually supplied with this machine and the turret is also standard. The operator places the shell in the chuck and, on starting the machine, the turret travels inwards and locates the shell at the correct distance in the chuck by means of a bracket mounted on the turret. The chuck tightens up automatically and the turret slides back. The arm at back holding the roughing tool now comes over and makes the first cut. The finishing tool in holder on the front sliderest then advances and makes the finishing cut. Immediately afterwards, the tool moves away from the work and the chuck automatically releases the shell which is removed by the operator. By means of automatic devices the spindle is stopped long enough to allow the operator to take out the finished shell and place another in the chuck. The motion of cam drum in the meantime is continued and does not necessitate stopping the machine. The turret is operated by a drum, while the arm at the back and also the slide rest are operated by cams located below the turret. The cutters are, of course, of special design to conform to the finished shape of copper band. The formed face of cutter being true for its entire length, the cutting face only need be ground to sharpen cutting edge. The copper band is now carefully gauged and the shell washed in a soda bath to remove all oil, etc.



CANADIAN LOCOMOTIVE CO. SHELL PAINTING MACHINE.

Varnishing.

The deleterious effect of picric acid upon steel renders it necessary to treat the inside of the shell with some substance that will withstand erosion. A special kind of varnish is used for this purpose, and it must be baked after application to secure hardness. The varnish is poured into the shell by means of a "Bowser" self-measuring storage tank. After the shell is filled, the varnish is poured back into the tank, leaving just a coating all over the inside except at the threads, which are protected by a



GAS HEATED BAKING OVENS SHOWING TRUCKING ARRANGEMENT.

hollow brass plug inserted before the varnish is poured in. The shells are next placed on a draining rack, nose down, previous to being baked. This rack consists of a wooden frame with steel bar sections and a strong steel netting below. The shells rest on the netting and drain into a tray underneath which catches the drippings.

Baking.

Four gas heated ovens are installed for the baking process. The back and outside walls are constructed of brick with steel top, partitions, floors and doors. Under the floors are the gas burners, three for each oven connected to short length pipe outside at the front. The sections have separate connections with the main, thus making it posible to operate any individual oven independent of the others. Each oven has its own set of rails for carrying the trucks, the tracks extending outside. The trucks, four in number, are made of steel and are divided into 120 sections for holding an equivalent number of shells. The shells remain in the oven for 8 hours at a temperature of 300 deg. Fahr. A thermometer on the top of each oven indicates the temperature inside. Each oven door has a balance weight for keeping the door open or closed as the case may be.

Inspection and Painting.

After the shells are taken from the baking oven, the hollow brass plug is removed and the shells undergo the final Government inspection which consists of gauging, weighing, etc. They are then ready for painting. The painting machine installed at the plant under notice was made by the Canadian Locomotive Co., Kingston, Ont., and was specially designed for this class of work. A general idea of the detail of this machine will be seen from the illustration. Briefly, the machine consists of a circular revolving table supported on a frame at a convenient height from the ground. On the top of the frame, and aranged equidistant, are sixty hinged bolts for holding the shells. Previous to being painted, a brass casting is screwed into the nose of the shell, the other end of casting fitting over the hinged bolt.

In operation, the table, driven by a belt, revolves. The painter takes his brush and pushes the shell inward. This causes the bevelled friction surface on the brass casting to come against the bevelled surface of the central revolving table. The shell is thus rotated and the paint applied with the greatest ease. The shells are given a priming and a finishing coat and the nose painted red as in the case of shrapnel shells. Under the table of the machine is a gas heater for drying the painted shells; the frame being covered in on this account. The paint can is supported on a holder outside the machine at the end of an overhanging arm which is pivoted on the post at the centre. After the final coat, the brass casting is unscrewed from the nose and a brass plug screwed in, this plug being similar to that used for shrapnel shell. The shells are now ready for shipping and are packed in strong wooden boxes in lots of six.

General.

It should be understood that this plant is laid out to suit the order of the various operations, thus a minimum amount of labor is entailed in handling the shells. However, trucks are necessary at some stages, and "Chapman" trucks are used for this purpose. To those familiar with the manufacture of shrapnel shells, the absence of heat treatment for lyddite shells will be of special interest as this constitutes one of the most difficult operations that the manufacturer has to contend with in making shrapnel. In making lyddite shells, the scleroscope test is also dispensed with, as is also the preparation of a test piece for Government inspection. A nosing press is not required, which is another saving in outlay and equipment. There are, of course, no bullets in a high explosive shell. The shell is empty when shipped from the shop, the explosive, fuse plug, etc., being added later.

THE SUBMARINE IN WARFARE.

So far as the war has gone, says a correspondent of the Liverpool Journal of Commerce, one type of craft that has proved itself to be more effective than was anticipated is undoubtedly the submarine. It has shown itself to be an almost perfect defence of a coastline against hostile war craft of even the latest and heaviest type. It has proved the most, and, in fact, one might say, the only really formidable weapon against the modern battleship, and has, indeed, rendered it unsafe for large war vessels to patrol the seas. Also leaving aside the question of legality of the new German method of warfare, the submarine has become the strongest possible danger to merchant shipping, thus putting a nation with a relatively weak navy more nearly on a level with a predominant Sea Power.

Starting the war with about 15 submarines of the sea-going, long-range type, and probably never more than 20 at any time, the Germans have been able to sink 12 British war vessels, including three battleships and three large cruisers, and to destroy more than 100 merchant vessels. This, of course, as we know, does not necessarily imply that this latter fact is important from the naval aspect, but it shows us we now have to reckon with the possibility in any future wars of a similar course of action being pursued by one of the warring nations.

Future Naval Design Policy.

No other type of war vessel has done anything approaching the same effective work as the submarine, and from a superficial survey of the whole problem, it might be thought that this has already, once and for all, solved the question of the policy which must be followed in naval design in the future. It might, for instance, be deducted that we, among other nations, must concentrate upon the construction of submarines on an enormous scale, even to the exclusion of building large capital ships. Yet it is obvious, if the matter be carefully considered, that what is undoubtedly the correct policy for one nation would be quite inadvisable in the case of another. In particular a strong naval Power must always keep the offensive most clearly in view, whilst a weak naval Power must necessarily rely upon defensive tactics.

In a sense, the submarine is both an offensive and a defensive craft, but essentially it is the latter, since if we presume that submarines were capable of sinking all the large vessels of an opposing fleet, they would as at present constructed still be incapable of taking the offensive by bombarding an enemy coast or aiding in the landing of an expeditionary force on the hostile coast. Yet against this it has to be remembered that battleships or other surface vessels are in most cases unable to carry out such work, as has already been only too clearly seen during the present war.

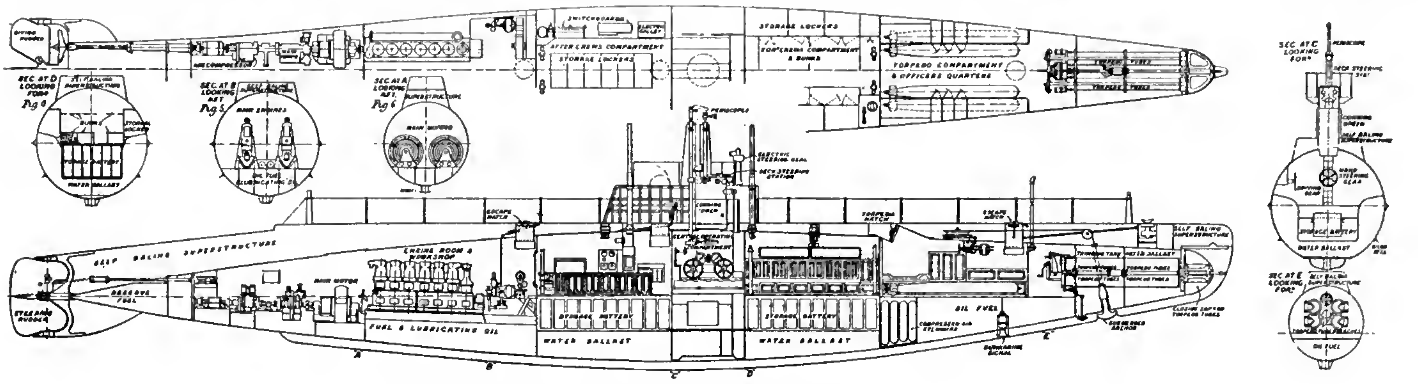
Submarines, if in sufficient number, can always prevent the approach of transports, although they cannot destroy the submarines opposed to them. In fact, it seems that by a combination of a large fleet of submarines, the prolific laying of mines, and effective fort guns, it will be almost impossible for any Power however strong it may be on the sea, to allow its fleet to cover the landing of an army upon hostile shores. In other words, the submarine has added so enormously to the defensive power of any nation that in course of time an invasion by sea will become an impossibility, even in the case of those countries with a very long sea coast and a relatively small fleet.

Naval Predominance Affected.

So much has the submarine thus altered warfare that, from the purely naval standpoint, the predominant sea Power could never inflict a total defeat upon a minor sea Power in the sense of so completely destroying the smaller navy that a landing on a hostile coast could be effected by its aid; for even the destruction of all the submarines—a difficult enough task—would still leave the minefields and fort guns.

The submarine will, therefore, have a

very strong influence upon military tactics in the future, and in particular for those countries which do not adjoin other countries with whom they may, under any conceivable conditions, be at enmity. It follows from this that the submarine has practically rendered Great Britain immune from invasion under any circumstances although it should be added that our submarine fleet has not yet attained such proportions as to guarantee this condition at the present time, and when it has there is always the distinct possibility that some new method of warfare will have been developed.



MODERN TYPE SUBMARINE DESIGN AND LAYOUT—I.

Destroying Submarines.

Submarines cannot destroy submarines, as battleships can destroy battleships, and according to past experience it is not by any means simple for any other type of craft to bring about the destruction of submarines in large numbers. It is true we can help in this direction slightly by building an enormous number of destroyers, but, on the other hand, these are costly vessels in comparison with submarines, and the number required is so very large that one doubts if this method of attacking the submarine problem will ever be carried out on such a scale as to give security of feeling against the depredations of the submarine. The point of importance to be noticed here is that, whilst surface vessels must almost invariably act in flotillas, except, perhaps, very fast destroyers, which can escape from any slower boats, the submarine works most efficiently in single units, and this has been well shown by the recent German tactics.

The time is already here, therefore, when we should consider to what end the path along which all naval progress is tending will lead. We must open our eyes to the dangers of the future, and make preparations accordingly, not after peace has been declared, and we find we have given away some important points, but long before the question of the terms of peace is even discussed.

We must now and onwards continue to develop submarines in this country with more urgency than ever before, and not only must much larger numbers be built in view of possible contingencies, but progress must be made with the type of submarine constructed, particularly in the matter of speed (which means progress in Diesel engine construction), and also in the possibility of under-water craft taking the offensive on a large scale.

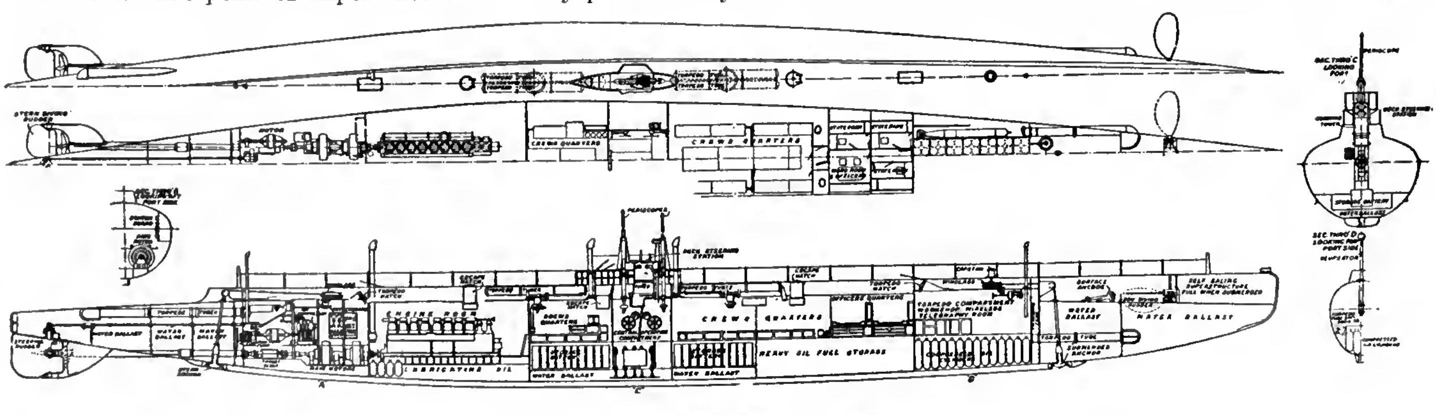
SHRAPNEL SHELL EXPLOSIVES.

THE main propelling charge is invariably of smokeless powder; this is relatively difficult to ignite and a completely satisfactory primer has yet to be found. In every respect save that of smoke, black powder makes the best primer; Krupps use a special cloth woven from guncotton yarn. Most of the smoke produced by modern ammunition is due to combustion of particles abraded from copper driving ing band and is thus hardly avoidable. The mechanical form of the explosive differs in shells of various nationalities.

In American shrapnel, perforated cylindrical grains of nitro-cellulose (about ⅜ in. long by 3-16 diameter) are used. The advantage of perforation lies in greater burning area and more constant surface than that of interstices between cords or strips, so that regular ignition and complete combustion are obtained. On the other hand, unless pressed hard, perforated granules are liable to crush under the gas pressure developed.

German ammunition uses bundles of stick nitro-cellulose about 9 inches long. Cordite has been much used in our shells in the past, but now a crystalline explosive, similar to that in Russian shells, is generally employed. French strip powder (about ½ in. by 1-64 in.) is used in 6-inch lengths. For the bursting charge, black powder is always used, since it gives the right sort of impulse to the bullets and is not affected by the shock of firing the shell.—Engineering Review.

Concerning Shell Orders.—The Canadian Shell Committee have, we understand, advised all those engaged in making shells not to wait for formal orders in the future, but to go ahead and manufacture to capacity.



MODERN TYPE SUBMARINE DESIGN AND LAYOUT—II.

Shrapnel Shell Manufacture

Shell Department of an Air Compressor and Pneumatic Tool Works

Staff Article

To those who have followed our series of articles on "Shrapnel Shell Manufacture in Canada," it will have become long ere this apparent that wide as is the diversity of product of our engineering and metal working plants, nothing in the nature of this new specialty they have been privileged to produce has been in anywise a deterrent to successful accomplishment. The shell department of the plant here described is no exception in this particular feature.

AMONG the large number of shops manufacturing shrapnel shells to-day in Canada, the most interesting ones, from a mechanical standpoint, are those which utilize most fully their standard equipment. This is especially true, because the engineer in charge, or the shop superintendent, must needs have displayed considerable ingenuity in making tools, jigs, and fixtures. The product of the shop about to be described, in times of peace, consists of steam and motor driven air compressors, and pneumatic tools. There are, of course, other lines manufactured as well, but those mentioned will give the reader an idea of the varied nature of the product, and at the same time the varied nature of the machine tools used to produce same.

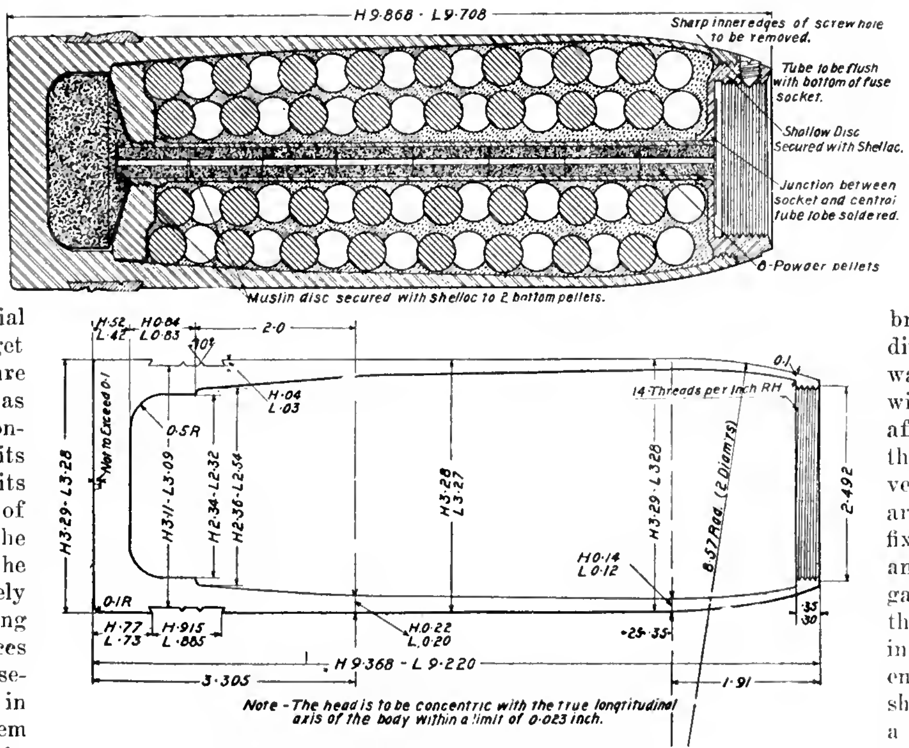
This particular shop was among the pioneers of the Canadian shell industry; in fact, it was our first industrial plant to actually get into the manufacture and to ship shells. It has not, however, been content to rest on its laurels, but has kept its production up to that of the largest shops in the Dominion to-day. The tooling is also extremely interesting, there being a number of devices which are not used elsewhere. Weak spots in the whole shop system are conspicuously absent and the engineering staff are to be congratulated on their high degree enterprise.

Receiving Shells and First Operations.

The shell forgings are received in carload lots from the forging plants, the various shipments having had heat numbers assigned to them there. These heat numbers are useful in determining the heat treatment at a later stage of manufacture. Thus, the shells in one series are all kept together. The word "series" is here used with regard to a number of shells which bear the same heat number. Later the word "series" will be used in another connection.

Sometimes all of a car load of forgings have the same heat number, and then again, among the carload, several numbers may be found. The shell forgings of one heat number all have the same percentage of carbon, hence the importance of keeping a series intact. These heat numbers are removed in the process of rough machining, but on the interior of the shell a daub of paint is placed, a different color representing each heat number. A number of colors which are impossible to mistake are used and a record is kept of all the numbers, and colors assigned to them.

After the shells are received, they are immediately given their "daub" of paint and are placed on trucks, each holding about one hundred forgings. They are then taken to an elevator and carried to the first floor above the receiving floor, where the shell shop is located. On the side of each shell a paint brush, which has been dipped in whiting and water, is drawn lengthwise. This marking, after it has dried, leaves that portion of the shell very white. The shells are next placed on the fixture shown in Fig. 1, and are marked. The gauge is used to scratch the shell, and this mark indicates where the open end is to be faced. The shells are now placed in a Hurlbut-Rogers cutting-off machine, and



BRITISH 18-POUNDER SHRAPNEL SHELL.

are chucked in a universal chuck. Two tools are power fed into the work and the ragged end of the shell is removed. The tools are then drawn out of the work and a rough reamer with a 45 deg. taper is pushed into the shell by hand and all interior burrs are thus removed. This reamer and the fixture in which it works are shown in Fig. 2. Water is used as a lubricant on nearly all the machines in the shop. Some machines have individual pumps, while others are supplied from the small mains which run through the shop. It is from the latter source, that these two Hurlbut-Rogers machines, used in this operation, are supplied. The pump that circulates this soda water cutting lubricant is a little triple vertical belt driven machine, manufactured by W. & B. Douglas, Middletown, Conn.

Rough Turning.

The shells are next carried on Chapman and Cowan elevating trucks and platforms to the various lathes engaged in the rough turning. Several types of lathes are employed, and also various ideas of tooling. Perhaps the most interesting machine is the John Bertram & Sons, Dundas, Ont., engine lathe shown in Fig. 3.

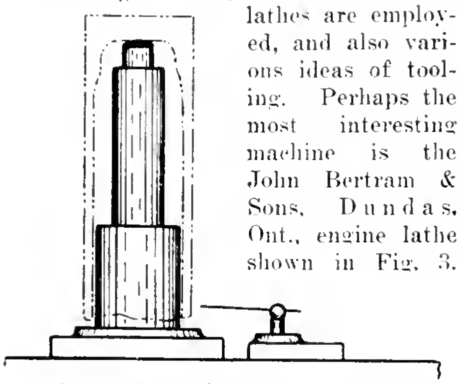


FIG. 1. MARKING-OFF THE SHELLS.

The chuck which grasps the shell is an expanding arbor operated by air. The lathe is of the hollow spindle type, and the air cylinder is placed on the far side of the head-stock. The details of the air chuck are shown in Fig. 4. A special cross slide carrying a turret tool holder is mounted on the carriage. There is, however, but one tool used in this operation, this being traveled along the shell until about two inches of the open end. The diameter is checked-up with calipers and limit gauges. When the tool arrives at this point it is gradually pulled out of the work by hand, forming a rough taper. Finally, when only a light cut is being taken, it is allowed to turn the last half inch of the shell straight.

This constitutes the rough turnings operation. The air chuck is one of the most useful devices yet found, the production on this machine having increased about twenty per cent. since the chuck was placed in service. It is not now necessary to ever stop the lathe to chuck a shell or remove it.

Another interesting lathe is a Lo-swing lathe manufactured by the Fitchburg Machine Works, of Fitchburg, Mass. Fig. 5 shows this machine. No special chuck is fitted, but a special mandrel,

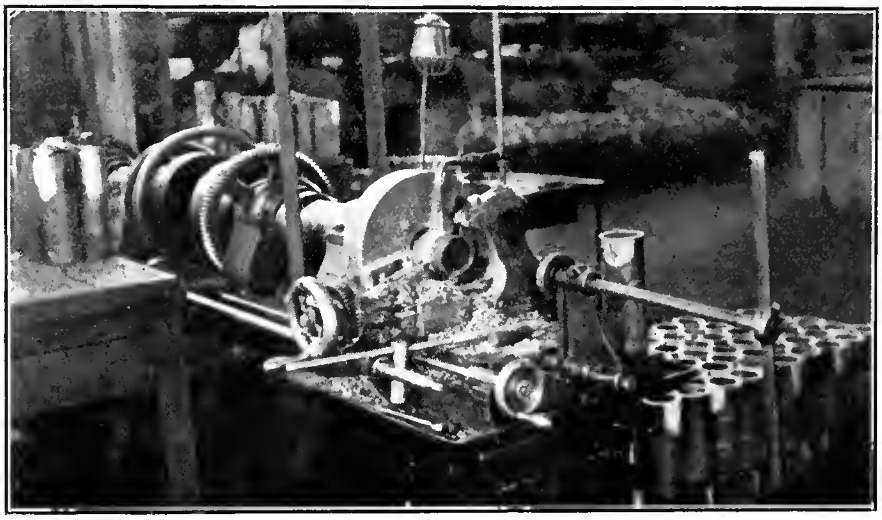

FIG. 2. CUTTING OFF OPEN ENDS OF SHELLS ON A "HURLBUT-ROGERS" MACHINE.

Fig. 6, is placed in the shell. This mandrel is forced into the shell in a Greenerd arbor press. For turning in the Lo-swing with this mandrel, a centre must be placed in the back end of the shells, and this is done on a little drill press. The jig shown in Fig. 6 is placed on the drill table, and the hinged strap A is placed over the top of the jig. A small drill, 5-32 inches in diameter, is run through the pilot hole, care being taken not to have this hole too deep because the back end of the shell when finished must have no marks on it. Thus, the drill is equipped with a stop. The hinged strap is then swung open and the shell and jig are shifted over under the

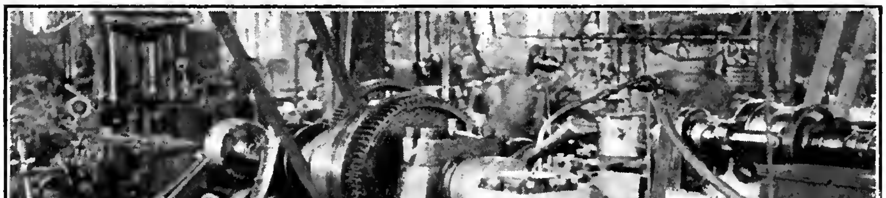

FIG. 3. ROUGH TURNING SHELLS ON A "BERTRAM" ENGINE LATHE EQUIPPED WITH AN AIR CHUCK.

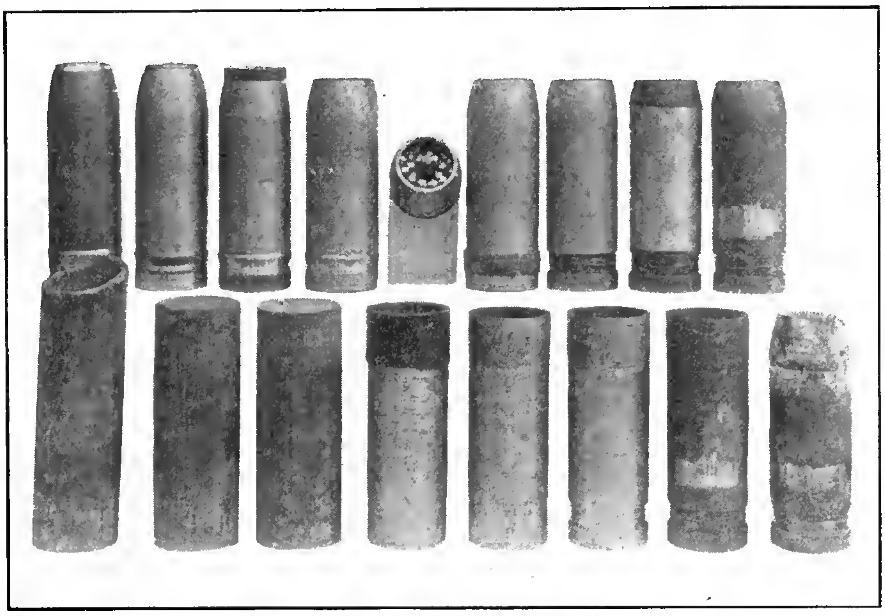
second spindle of the drill press. A tool which forms the centre is carried in this second spindle. A little white lead is put in the centre before placing in the lathe, and a dog placed on the mandrel drives the shell.

The shell is turned straight, from the back end up to within two inches of the open end. A rough taper is then turned and the last half inch of the shell is barely cleaned up and turned straight. One tool accomplishes all this through a modification of the taper attachment of the lathe. A second tool is used to finish turn the base end of the shell up as far as the driving band groove, this tool entering the work while the roughing tool is also turning. Calipers and limit gauges are used to test the work.

Several other lathes are used in this operation, all of which are hollow spindle machines with expanding arbors fitted to them. The arbors are operated through a hand wheel which is keyed to a rod extending through the hollow spindle of the lathe. The first in this group is an F. E. Reed engine lathe. The



SHELLS IN PROCESS FROM THE FORGING TO THE PRODUCT AS COMPLETED IN CANADA.

shells dealt with here have a centre in the back ends, the tail stock being brought forward and the outer end of the shell supported by this centre. The next machine is an American Tool Works engine lathe, the centre in the tail-stock of same being used to support the outer end of the shell. A John Bertram & Sons engine lathe is also employed for a similar purpose.

Two Gisholt turret lathes are fitted with these expanding arbors. The tools are carried on the cross slide, and in one instance the turret carries a centre which supports the outer end of the shell. In the case of the other lathe, the outer end of the shell goes unsupported. To each of these chucks there are two sets of three jaws, the jaws being pulled out of the work by small circular pieces of flat spring steel which have been split. One of the Gisholt turret lathes carries a small dog on the inner end of the shell to relieve the mandrel from the whole driving strain. Only one tool is used on all these rough turning lathes except in the case of the Fitchburg Lo-swing lathe.

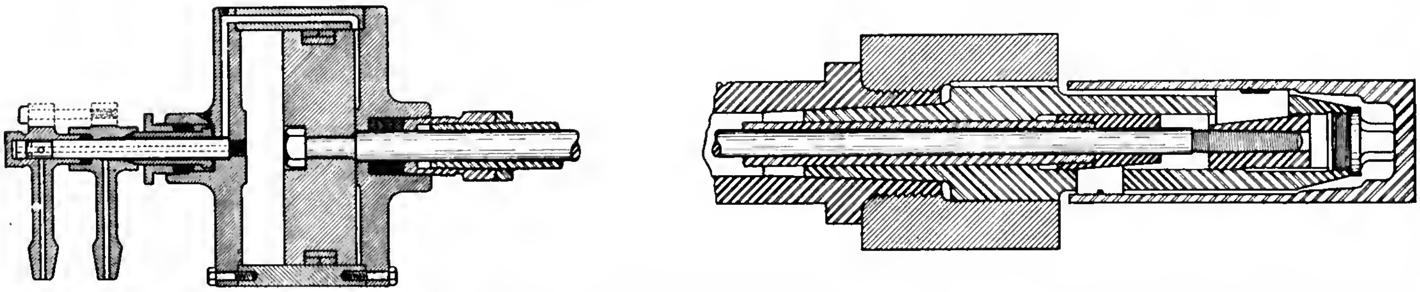


FIG. 4. DETAILS OF AIR-OPERATED CHUCK ON A "BERTRAM" HOLLOW SPINDLE ENGINE LATHE USED IN ROUGH TURNING OPERATIONS.

Rough Facing Back Ends.

The shells are next taken to the large boring mills, where the back ends are faced off. The first machine on this work is a Baush Machine Tool Co., of Springfield, Mass., vertical boring mill. On the table a jig is placed to which twenty-four shells can be bolted. Both heads of the machine are utilized. On one head the first tool is carried, this tool being set so as to take the first cut which varies considerably in different shells. On the other head three other cutting tools are carried which remove more metal from the back of the shell. Thus the strain upon the machine is divided. Fig. 7 shows the machine at work.

A similar Bullard boring mill is used to accomplish this work, a second jig to which twenty-four shells are clamped being used. Only one head, however, is employed, three tools being mounted on it. A third boring mill, also a Bullard vertical machine employed on this work is fitted with a chuck, and only one shell at a time is faced.

It is proposed in this shop to fit up a large Ingersoll miller and in the near future this machine will no doubt take care of the larger part of the work involved in rough facing the shell cases.

Finishing Back Ends.

The finishing of the back ends is done on a variety of small lathes, the operations largely resembling each other, although several types of chucks are used. There are two small John Bertram turret lathes, these being fitted with hinged chucks which screw on to the live spindles of the lathe and are supported in an outer bearing. These details are clearly shown in Fig. 8, which illustrates one of these machines.

The operation consists of finish facing the back end and finishing the outside diameter of the shell from the back end up as far as the driving band recess. Then a radius of 1-10 of an inch is turned on the corner at the base. These operations are usually accomplished with one tool, the cutting edge of which has been ground to a special profile.

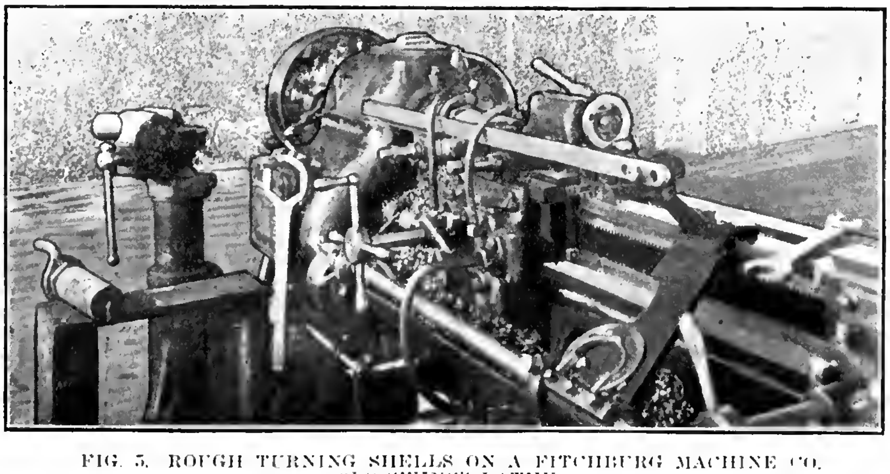

FIG. 5. ROUGH TURNING SHELLS ON A FITCHBURG MACHINE CO. "LO-SWING" LATHE.

Two other lathes

engaged in this work are R. McDougall, Galt, Ont., machines. One is equipped with a split collet chuck carried in an outer bearing. As the nose is at this stage of manufacture the largest diameter of the shell, a split bush is slipped over the latter and the collet jaws tighten down on the bush, thus the shell is quickly and easily gripped in the chuck. The second chuck is a hinged pattern carried in an outer bearing. These operations are final on the back end of the shell, and are followed by that of boring.

Boring.

The shell now passes on to the Jones & Lamson turret lathes where the powder pockets and diaphragm seats are bored. Four Jones & Lamson flat turret lathes and two more J. & L. turret lathes of an older design, are all employed for the same purpose. Each lathe is equipped with a hinged chuck and the shells are placed in these up against a stop. The boring tools are quite simply arranged. One bar extends across the turret and the end extensions are the boring bars carrying the boring tools. The roughing cutters are carried on the one end extension, that is, the roughing cutter which bores out the powder pocket and the diaphragm seat. On the clamp nearest the roughing bar extension, two fixtures are bolted which carry two small tools. These tools rough turn the outer diameter of the shell and face the end of it. By referring to Fig. 9, a diagram of the tooling is shown. The lathe is equipped with stops which govern the depth to which the tools enter the work.

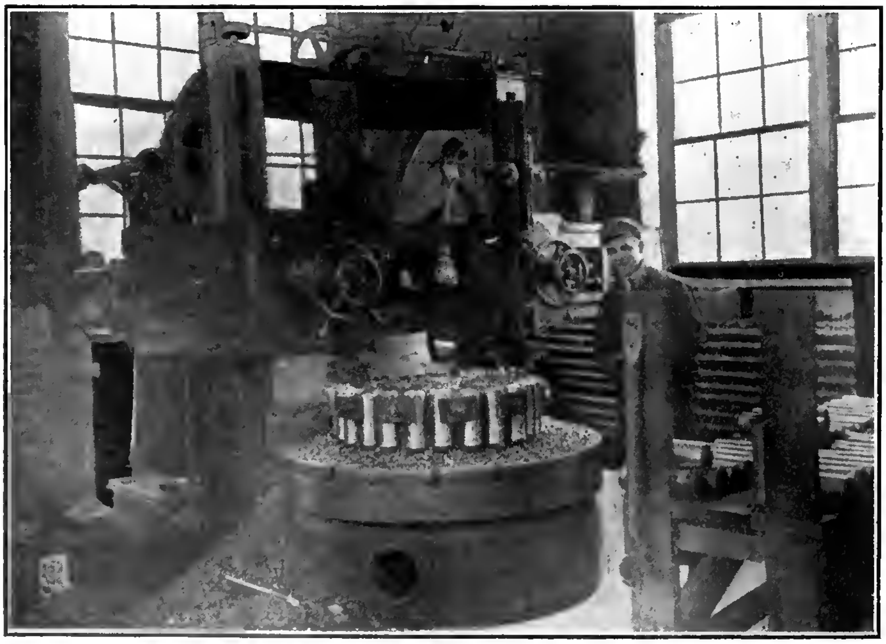

FIG. 7. FACING BACK ENDS OF SHELLS ON A "BAUSH" BORING MILL.

On the opposite end extension, the finish cutters are carried, and, as in the case of the roughing cutters, these cutters are made from one piece of steel. The cutter has two cutting edges which are ground so as to form the powder pocket and diaphragm seat. The tool is placed in the bar horizontally, and held

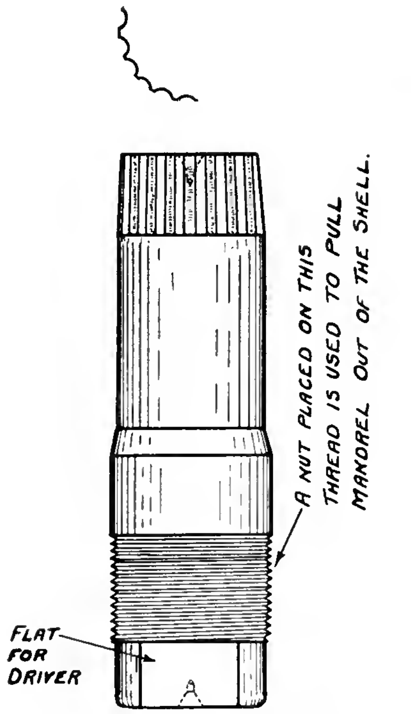

FIG. 6. MANDREL USED IN ROUGH TURNING OPERATIONS ON "LO-SWING" LATHE.

firmly there by means of the shape (being dovetailed into the bar) and two set screws. The finish cutters are fed into the proper depth against stops. Fig. 10 shows a three-hundred and fifty-pound operator on one of the Jones & Lamson flat turrets. Soda water cutting lubricant is fed to the cutters through ducts in the boring bars, and all of the six machines engaged in the boring operation are tooled up in a similar manner.

After the boring operation, the thickness of the metal in the bottom of the shell is tested with the gauge shown in Fig. 11, at A. The gauge B is used to

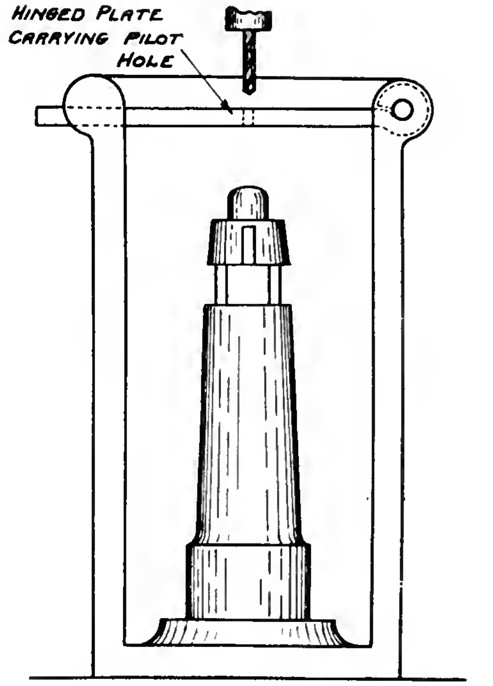

FIG. 6. JIG ON DRILL PRESS TABLE FOR CENTERING BASES FOR TURNING ON "LO-SWING" LATHE.

test the length of the shell. From these machines the shell passes on to have the driving band recess cut.

Machining the Driving Band Recess.

The operation of turning the driving band recess is done on three Potter & Johnston "automatics," as shown in Fig. 12. The shell is placed in a universal chuck, up against a stop, and a tool advances from the rear of the machine and roughs out the groove from the under side of the shell. The tool turns to finish depth on either side of the groove but leaves sufficient metal for the wave lines to be later formed in the central portion of the groove. Then the undercutting tools from the rear enter the work and undercut the edges of the groove. After this operation, the wave-forming tool from the front of the machine advances toward the work. This tool has its cutting edge so formed that it leaves two small "V"-shaped ridges. A three-pointed cam bolted to the face of the chuck communicates to the tool-holder a lateral motion which transforms the "V"-shaped ridges into waved lines. These operations are so arranged as to be automatic, and, after the shell is chucked, nothing need be done by the operator until it is necessary to remove the shell. Lard oil is used as a cutting lubricant on all three machines, and is, of course, supplied from an oil pump which forms part of the machine itself.

Two other machines are employed to

accomplish the machining of the groove. These are a Jones & Lamson turret lathe and a John Bertram & Sons engine lathe. The shells, however, have the groove roughed out and formed on a John H. Hall & Sons cutting-off machine, before being set up in either of these two machines, this one Hall machine being quite capable of feeding the other two machines. The shell is simply chucked in a universal chuck and a rough-turning tool is fed into the work. This rough-turning tool cuts the groove roughly to width. The outside edges of this rough turned groove are cut to depth, while sufficient metal is left in the central portion of the groove to allow of the wave lines to be later formed. This operation is of rather short duration, thus the machine is able to feed a Jones & Lamson turret lathe and a Bertram engine lathe in performing the finishing operations.

The Jones & Lamson turret lathe is equipped with the tooling for finishing the groove as supplied by the manufacturers. A little fixture has, however, been added at this shop in connection with the under-cutting tools. One under-cutting tool is fed from the rear of the machine and the other from the front. The little device added here centres these tools when they are not being used, thus allowing the shell to be placed in the machine and removed without coming into contact with the tools.

The Bertram engine lathe is fitted with the Bertram recessing and wave line forming attachments, already described in previous issues of Canadian Machinery. With the completion of the recess, the shell is ready to pass on to the heat treating department.

The hardening furnaces and oil tanks are located in the blacksmith's shop, a general view of the hardening department being seen in Fig. 13. The large furnace shown in the background is a

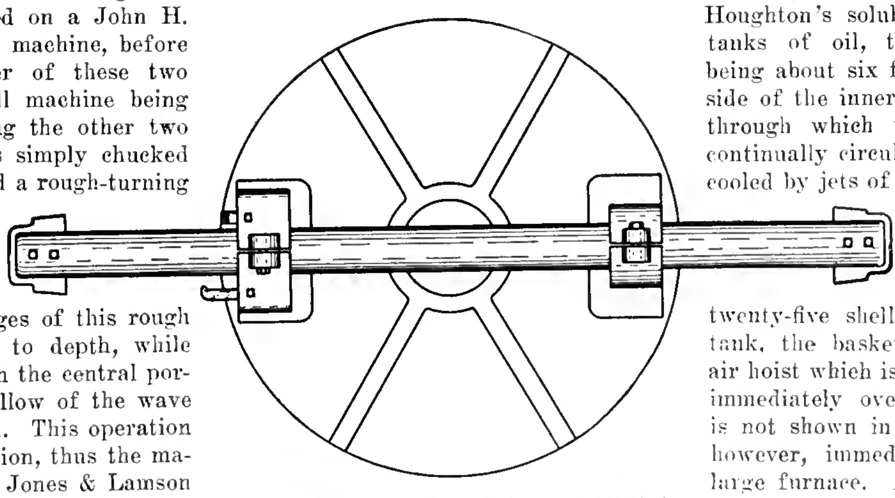

FIG. 9. SIMPLE TOOLING ON A "JONES & LAMSON" TURRET LATHE FOR BORING.

Brown & Sharpe product fitted with Ferguson oil burners. This furnace accommodates twenty-five shells in a batch. They are placed in the ovens one at a time by the tool shown in Fig. 14, and are raised to a temperature of 1450° F., being allowed to stay in the furnace from twenty-five to thirty minutes. The door of the furnace is fitted with a counterweight and is easily operated. There are five smaller oil furnaces each able to take care of eight shells, of which usually three take care of the annealing and two the hardening. They are so fitted, however, that they can be used for either purpose. These smaller furnaces were built by the Canadian Ingersoll-Rand Co., Sherbrooke. All the furnaces are equipped with Bristol pyrometers.

The shells are lifted from the smaller furnaces by specially made tongs, and are pulled from the larger furnace by means of a poker out on the platform in front. From there the shells are taken by tongs and placed in tanks of Houghton's soluble oil. There are two tanks of oil, the smaller of the two being about six feet by three feet. Outside of the inner shell is a water jacket through which water from the mains continually circulates. The oil is further cooled by jets of compressed air and cold water coils in the bottom of the tank. One large woven wire basket containing twenty-five shells is submerged in this tank, the basket being handled by an air hoist which is suspended from a point immediately over the tank. This tank is not shown in Fig. 13; it is situated, however, immediately in front of the large furnace. At one end of the tank is placed an inclined shelf on which the shells are placed to allow the oil to drain from them.

The second oil tank is slightly larger than the first. It is approximately seven feet by three feet, and is equipped

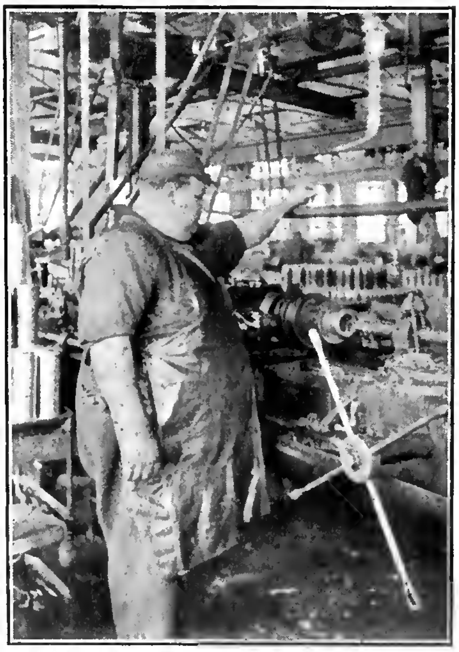

FIG. 10. BORING ON A "JONES & LAMSON" TURRET LATHE.

somewhat more elaborately with devices for keeping the oil cool. The tank is water jacketed similarly to that already described. Jets of compressed air are also employed, but perhaps the most interesting device is the employing of a Wainwright Evenflow Heater, manufactured by the Alberger Condenser Co., New York city, to cool the oil. A small centrifugal pump direct connected to a ¾ h.p. Sprague Electric Co motor circulates the oil through the coils of the heater. Water from the mains is also circulated through the heater, thereby absorbing a considerable portion of the

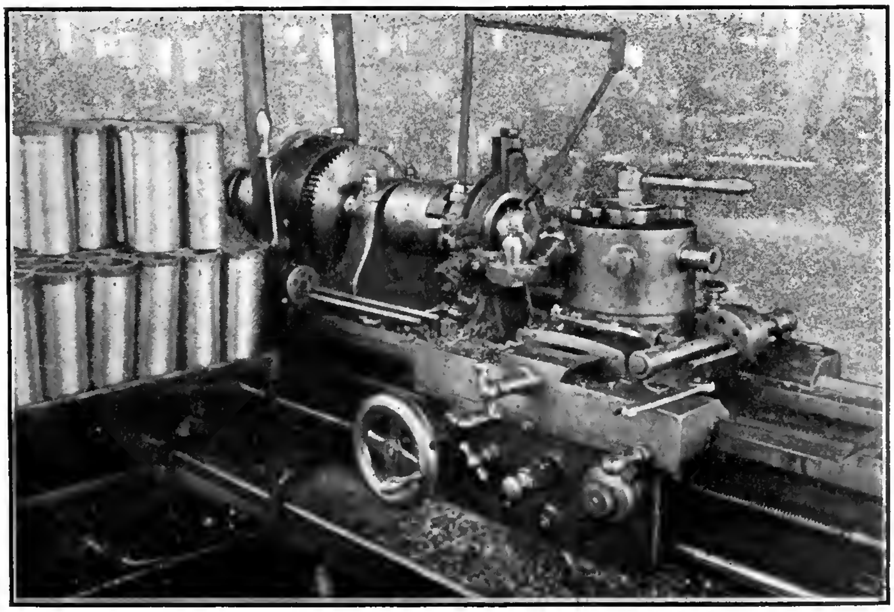

FIG. 8. FINISHING BASES OF SHELLS ON A "BERTRAM" TURRET LATHE.

heat from the oil. The connections of the heater had of course to be rearranged somewhat, but the results have been very gratifying. In addition, this tank also has cold water coils placed in the bottom to further assist in cooling.

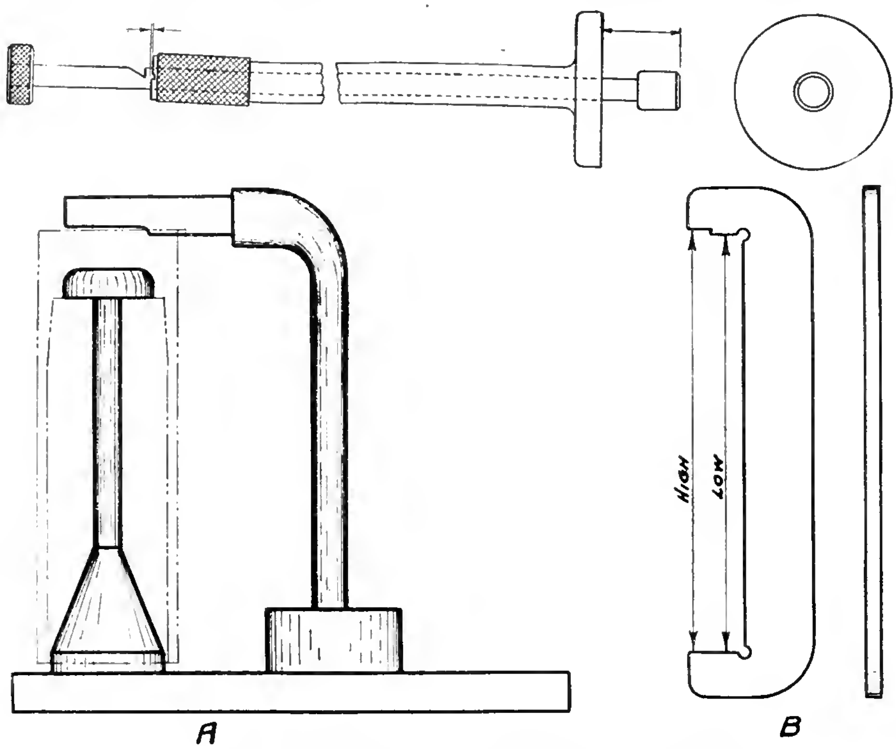

FIG. 11. GAUGES USED AFTER BORING OPERATIONS.

Two small woven wire baskets are placed in the tanks, each of which takes care of eight shells at a time. Handles, which also do duty as supporting hooks, come up over the edges of the tank, thus the basket is lifted by hand up to the shelf at the end of the tank, where it is placed to allow the oil to drain from the baskets and shells. The shelf simply consists of a couple of ¾ inch rods stretched across the tank just above the level of the oil. The shells in this case also are lifted from the baskets on to an inclined shelf where the oil is allowed to further drain from them.

Annealing is carried out in the small furnaces, eight shells to each. The annealing temperature is from 650° to 700° F., and the length of time required for the process is approximately half an hour.

Representative shells are next polished up on a small Landis grinder. The nose of the shell is placed in a small universal chuck driven by a single pulley and on that part representing the tail-stock, a revolving centre is mounted. Thus, the shell is held and revolved, while an emery wheel is brought up to it and a circle cleaned up near the recess. Testing with a Shore scleroscope follows. The methods employed to obtain uniform and satisfactory results from the hardening treatment will be found interesting.

Relative to Hardening Treatment.

As before stated, there may or may not be more than one heat number to a carload of forgings. Each heat number is, however, identified by means of its paint mark. Samples from each heat number are taken, and these are obtained from the ragged ends of the shell cut off in the first machining operation. The samples are examined, and, from experiments conducted, a heat treatment is established. This treatment is then applied to a sample bunch of three shells, and in most cases the shells respond to it. If, however, the shells do not respond, the whole lot of shells of that particular heat number is held up till a satisfactory heat treatment has been determined. When the samples come up to the required hardness the lot is put through. Should it become a difficult problem to get a certain batch of shells to respond to a heat treatment, analyses are sometimes taken, and the problem studied until satisfactory results have been obtained. After annealing, which will be remembered was accomplished in batches of eight, one shell in each lot of eight is cleaned up and tested with the scleroscope.

When one shell passes the scleroscope test, the lot of eight are taken to have passed. Fifteen lots of eight each are now placed on an iron table and the Government inspectors take two shells at random from the lot, being careful to always choose shells that have not undergone the scleroscope test. One of these shells is used for the tensile test and the other for the firing test. Here the shells lose their heat number identification and are made up into series of 120 each. Each series is given a number and this number is used to identify the series throughout the succeeding operations.

Shell Nosing.

The next operation is the nosing process. The shells are heated in a lead pot from which four pipes extend. They are slipped on to these pipes, and thus their noses are placed in the lead and heated. Each shell is nosed on a pneumatic nosing press, after which they are placed in a second lead pot and reheated for a few moments to a dull red. The shells are then placed, nose downward, in large trays of powdered mica. Four pipes for holding shells extend out of each lead pot, and charcoal is placed on the surface of the molten lead to reduce the oxidation of the metal to a minimum. Fig. 15 shows the lead pots and the nos-

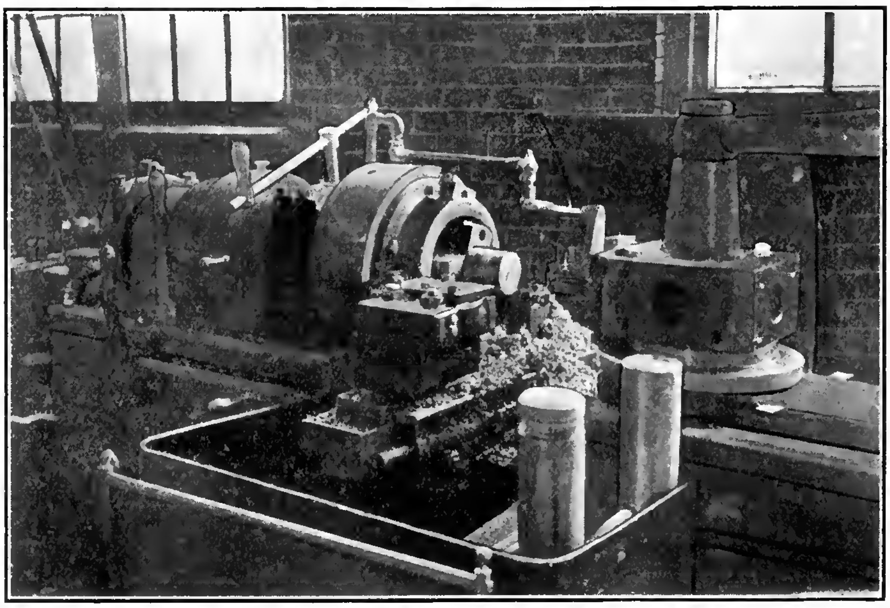

FIG. 12. RECESSING ON A "POTTER & JOHNSTON" AUTOMATIC.

ing press, while Fig. 16 shows the detail of the profile of the die used to nose the shell.

After the noses of the shells have cooled slowly in the powdered mica, they are removed to the foundry where they are sandblasted, all traces of scale being removed from the shell base, recess, and body.

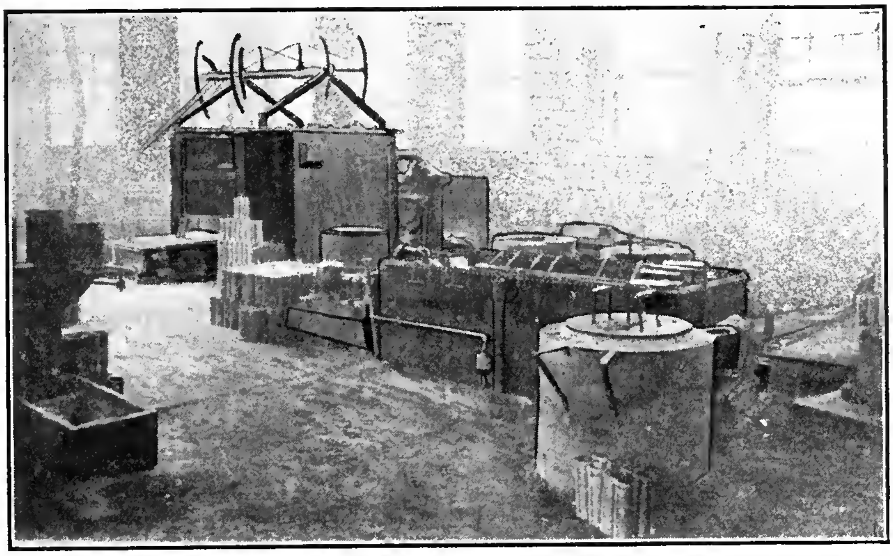

FIG. 13. HEAT TREATING DEPARTMENT.

Machining Inside of Nose.

Several machines are tooled up to accomplish this operation, the list including two London Machine Tool Co. engine lathes, one large Bertram engine lathe, and two small Bertram engine lathes, making a total of five lathes installed in this department. One or two other lathes located in adjacent departments are also tooled up to accomplish this operation should these first mentioned five lathes not be able to take care of the full number of shells sent to them. Fig. 17 shows a London Machine Tool Co. engine lathe fitted up with a turret on the cross-slide and tooled up to accomplish the operation, while Fig. 18 is a diagram of the tools and stops used. The shell is chucked in a collet chuck as can be clearly noted in Fig. 17. A stop in the chuck locates the shell.

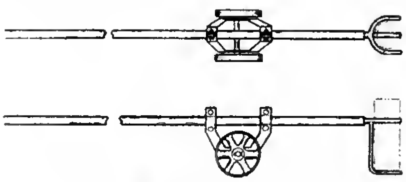

FIG. 14. TOOL FOR PLACING SHELLS IN LARGE FURNACE.

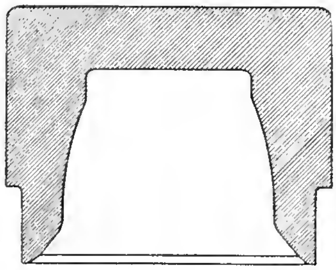
The first operation is to rough turn and form the outside of the nose. By referring to Fig. 18, the fixture, A, can be seen, being rigidly attached to the turret. On the cast iron fixture B, and bolted rigidly to it, is a forming-plate of hardened steel, the near side of this forming-plate being used to guide the turning tool mounted on the turret cross-slide. The tool is fed away from the head-stock, the pin in the fixture A is brought against the forming-plate and the tool located. The carriage is then travelled by power away from the head-stock of the lathe. Hand manipulation of the cross-slide keeps the pin in the fixture A, closely in register with the forming-plate, the outside edge of which is ground so as to form the proper contour of the nose.

The turret is next swung around and a boring bar carrying a boring tool and a facing tool is brought into position, the turret being located for this operation by the stop C. When thus located, the carriage is travelled by power towards the head-stock. The tool D bores the nose, and the tool E faces it. The carriage travels until its motion is checked by the stop at F, thus the nose is faced to length.

The inside of the nose is next turned and formed, the tool G being used for this work. This tool is guided by the forming plate attached to the fixture B. However, for this operation the inside edge is the forming edge. The pin in the fixture A is placed against the tail-stock end of the forming plate, thus the tool is located. The carriage is traveled by power and the pin in the fixture A is kept against the forming plate by the hand manipulation of the cross slide. In this way the inside turning and forming is accomplished.



NOSING DIE

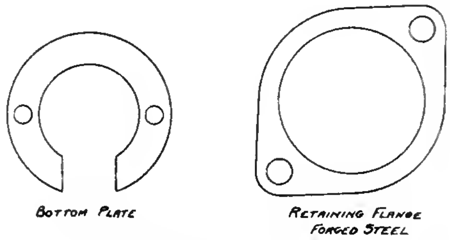


FIG. 16. SOME NOSING PRESS DETAILS.

The next operation is to ream the straight bore of the nose, a spirally fluted reamer being employed to do this work. The turret is centred by means of the stop C, and the reamer, which is of the shell type, is mounted on a boring bar. The turret being swung, the nose is tapped, two kinds of taps, being used

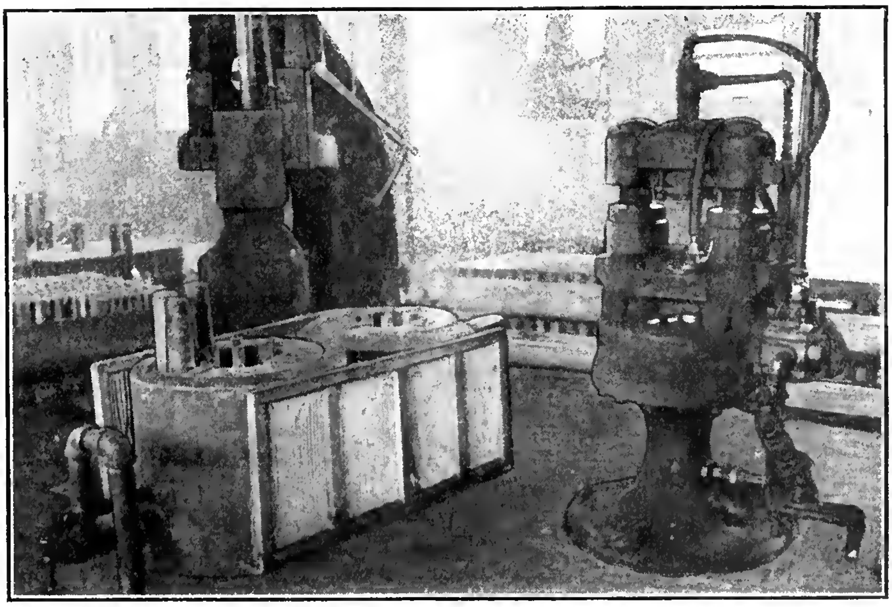

FIG. 15. LEAD POTS AND NOSING PRESS.

—the collapsible type and the ordinary type. The operation of the collapsible type of tap is easy to understand. The straight tap, however, is operated under different circumstances, the straight shank of the tap being fitted with two feather keys, and mounted on a bar fitted to the turret. This bar is of large enough diameter on that portion outside the turret—to be bored out to accommodate the shank of the tap, and two keyways are cut diametrically opposite one another to take care of the feather keys. The lathe is reversed to allow the tap to be withdrawn. Water lubricant is used on all tools in this operation. A very convenient little gauge is used, to test the thickness of the metal in the nose, this gauge being shown in Fig. 19.

The next operation is to put the sizing tap in the noses. This is done on an American drill press. The tap is started in by hand and the drill finishes the operation. Lard oil is used on the tap, but only in small quantities; the reason of this being that if there is any surplus oil in the shell when the resin is poured in, the latter will ignite it which is undesirable.

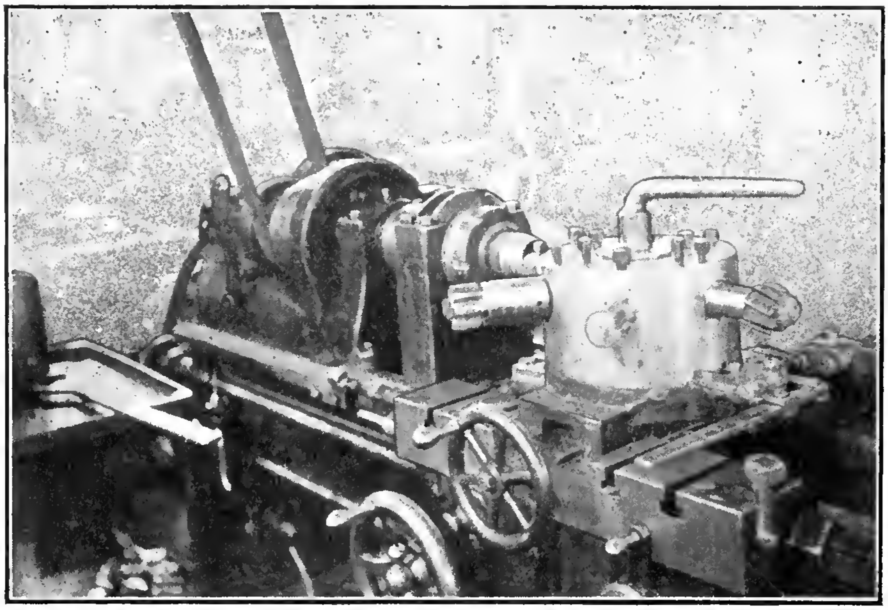

FIG. 17. FINISHING INSIDE OF SHELL NOSE ON A LONDON MACHINE TOOL CO. LATHE.

Finish Grinding.

The shell now has a centre plug screwed in the nose, being held in a clamp on a bench while the plug is screwed in. This bench, on which is located the clamp and the shells, being adjacent to the Landis grinder upon which the noses are ground, makes it very convenient for the operator to pick up his shells and place them in the machine. Fig. 20 shows the plug and the method of driving the shell in the grinders. The base of the shell is carried in a revolving centre mounted on the tail stock. The shells are ground to their exact shape, the wheel being dressed to do this. Care is taken, however, to dress the wheels frequently in order to produce perfect noses.

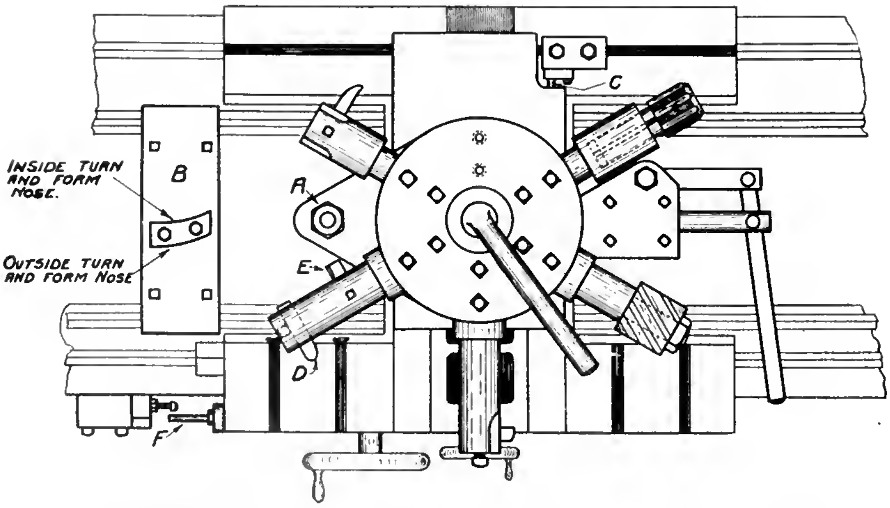

FIG. 18. LONDON MACHINE TOOL CO. ENGINE LATHE EQUIPPED WITH SPECIAL TURRET ON CROSS SLIDE AND SPECIAL TOOLS FOR MACHINING SHELL NOSES.

When the shell is removed from the machine, the operator places it on an inclined track, and it rolls by gravity down to the Norton grinder, on which machine the bodies are ground. A straight wheel of $6\frac{5}{8}$ inch face is used here to grind the bodies. The wheel grinds both the straight portion of the body and also a small bevel where the diameter of the shell is enlarged. The reason for the extra width of face of the wheel is to permit the latter to be worn away considerably before this bevel becomes too short. When the shell is removed from the body grinder, it is placed on another inclined track, and rolls by gravity back to the clamp on the bench where the plug is removed. Fig 21 shows the two inclined tracks and the grinders in the background.

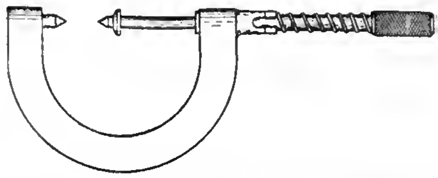

FIG. 19. GAUGE USED TO TEST THICKNESS OF METAL IN NOSE OF SHELL.

A rather unique scheme is being tried out in these operations. It consists of the water used on the grinding wheels being made to flush out the cuttings from the base of the machines and carry it all to a settling tank on a lower floor. From the latter, the water is pumped back again to the little mains which supply the lubricant to the various grinders. It has been found necessary, when these grinders, especially those operating on the bodies, are working at full capacity, to stop several times a day and remove the accumulation from the base of the machine, but with the new arrangement, it is hoped to be possible to operate the machines continuously. A duplicate set

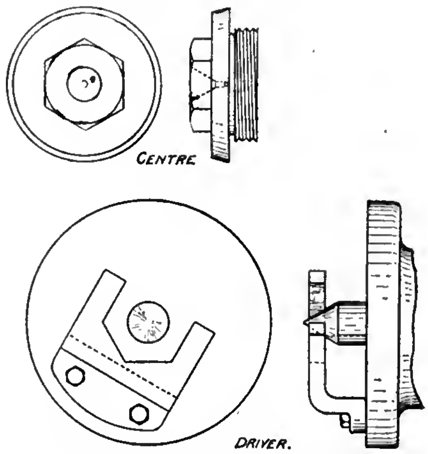

FIG. 20. TOOLS USED IN GRINDING OPERATIONS.

of machines similarly equipped to the one just described is installed, in which the nose grinder is also a Landis machine, and the body grinder a Norton machine.

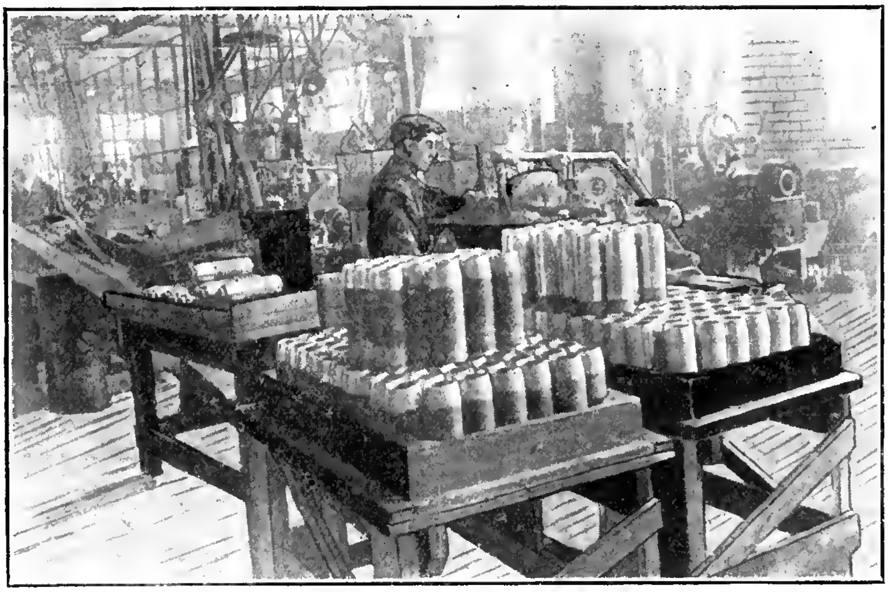

FIG. 21. GRINDING SHELL BODIES AND NOSES.

Pressing on the Copper Bands.

The shell now has the copper band slipped loosely over the base and into the recess, a blow from a wooden mallet being sufficient to hold the band in the recess. The band is then pressed on in the banding press, shown in Fig. 22. The press is operated by air, and was primarily constructed as an experiment, but, although more or less of a makeshift, it has done excellent work for many months. A crank has been fitted to a belt-driven counter-shaft, and through the medium of this crank the air valves are operated automatically. Should, however, it be advisable to stop the machine, it can be done simply standing on a foot lever, which throws the automatic valve gear mechanism out of commission; stepping off the lever throws the mechanism into commission again. Of course, a valve in the air line is also provided for long stops. This machine is capable of pressing on fourteen hundred bands in one day.

Turning the Copper Bands.

Three engine lathes are fitted up to turn the copper bands, the most interesting of these lathes being a London Machine Tool Co. product. This machine is equipped with an air chuck of the split collet type, and Fig. 23 shows the lathe. The shell is placed in the chuck and is located by a stop on the cross slide, and the roughing tool is carried in the standard tool-holder on the cross slide. The cross slide is moved up against a stop, the latter determining the depth to which the roughing tool shall be fed into the work. The finishing tool is carried on the vertical fixture mounted on the rear of the cross slide. This tool works in a vertical slide and shaves the band to size. Details of this tooling can be seen in Fig. 24. The other two lathes have not as yet been fitted up with air chucks, but, as soon as these can be made, they will be attached. The other lathes are—MacGregor, Gourlay & Co. and New Haven Mf'g. Co. products. These lathes are both fitted with collet chucks. Limit ring gauges are used to test the diameter of the band. From here the shells pass on to the assembling department.

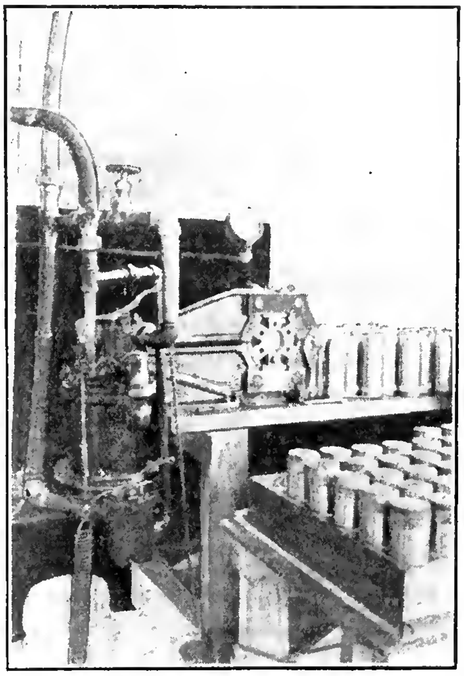

FIG. 22. BANDING PRESS.

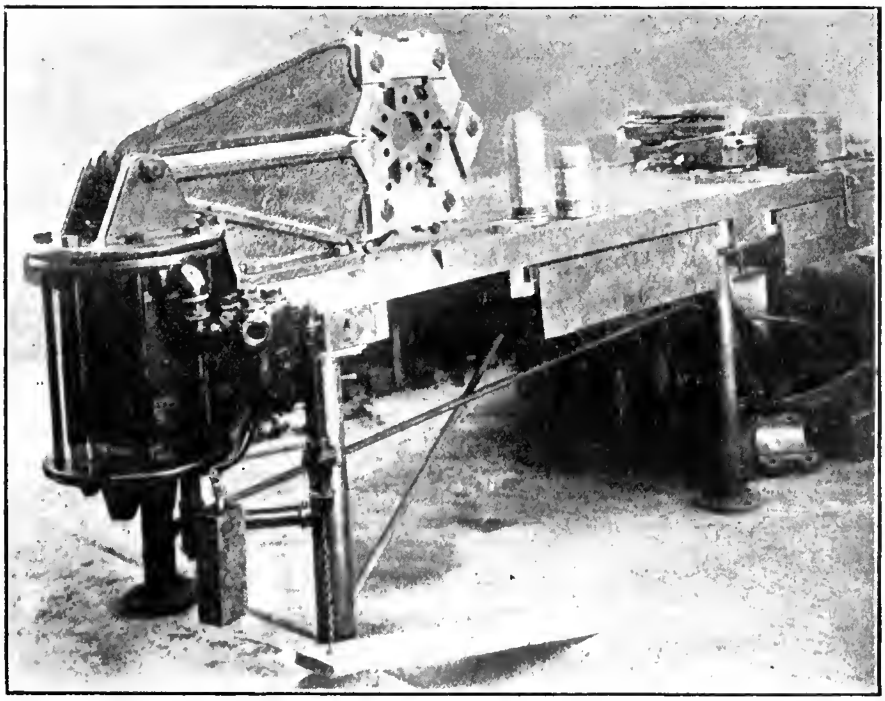

CANADIAN INGERSOLL RAND CO. BANDING PRESS.

The first operation in the assembling department is the marking of the shells on a hand-operated Dwight Slate stamping machine, following which the powder cup and brass tube are put in. The shot is then poured in from a huge wooden container, a funnel being placed in the nose of the shell, which funnel holds the upper end of the powder tube central. The shell is placed on an air vibrator, which was removed from a moulding machine, the shot being thereby jarred and packed in. Molten resin is next run into the shell from one of three electric resin pots, after which the shell is carefully weighed on a delicate balance. A very narrow margin separates the limiting weights; therefore, small shot are added as necessary.

The shell is next clamped in a hinged chuck, and the brass socket screwed

home after its thread has been thoroughly coated with red lead. Pipe tongs are used for the purpose. The shell is then passed on to the solderers. Solder is cut in rings and placed over the protruding end of the powder tube, electric soldering irons being used in making the joint. This completes the work of the assembling department, of which Fig. 25 is a general view.

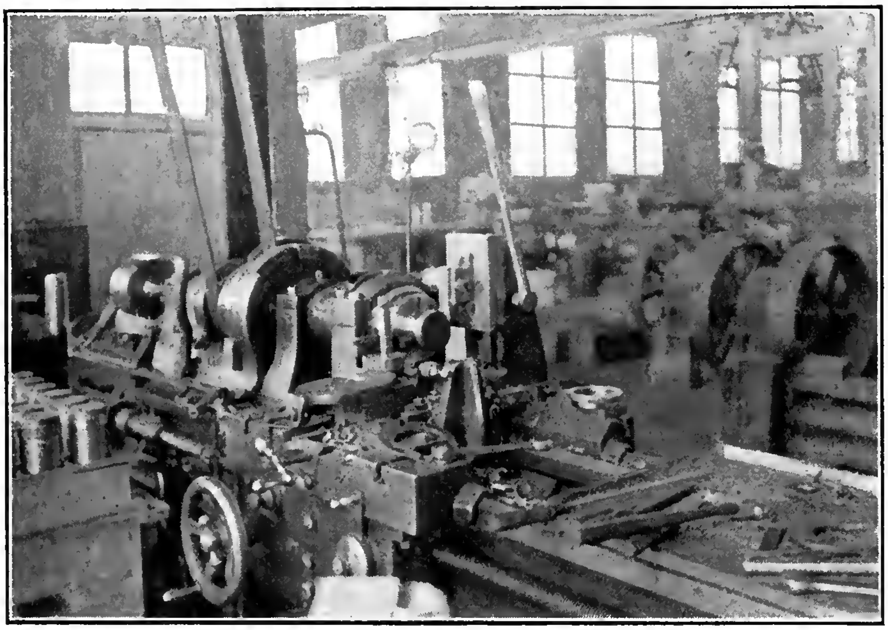

FIG. 23. TURNING COPPER BANDS ON A LONDON MACHINE TOOL CO. ENGINE LATHE.

Finishing Brass Sockets.

Three small lathes are fitted up to do this work. One is a Windsor Machine Co. turret lathe, one a Niles-Bement-Pond engine lathe, and the third is a Bertram turret lathe. The former machine, shown in Fig. 26, is equipped with an air chuck of the collet type. The tool for cleaning up the end of powder tube is carried on the turret, and the turning tools are carried on the cross slide. Some very ingenious stops are found on this machine, all of which tend to large production. A split collar is placed over the shell, so that when the collet jaws close they will come in contact with the split collar before the copper band is touched.

The Niles. Bement-Pond lathe is fitted with a special collet chuck, the details of which are shown in Fig. 27. The tooling on this lathe is somewhat out of the ordinary, all the tools being mounted on the cross slide. The tool for cleaning up the end of the powder tube is mounted on a fixture at the back of the cross slide, while the rough turning tool is on the central part of the cross slide and cuts from underneath. The finish turning tools are carried on the near side of the cross slide. The John Bertram lathe is tooled up with all tools on the turret.

Final Operations.

The shell now passes on to the final shop inspection. A sizing tap is run into the brass socket, and a rod is run down into the powder tube. All dirt is also blown out of the powder tin and tube by compressed air. Final Government inspection follows.

Painting.

After having passed the Government inspection, the shells pass on to the painting department. Fig. 29 shows the machine used for painting. The brass plugs are screwed in the sockets after the Government inspection and the square holes in these plugs are used to drive the shells in the paint machines, the outer ends being carried in revolving centres. The original machine was a bolt threader, built by the Webster & Perks Tool Co. The bases are painted with the shell resting nose downward in the block to the left of the machine. The shells are then placed in the machine and revolved, being thus horizontal when the bodies are painted.

A priming coat of black japan is applied to the shells, after which they are lifted from the machine by a special pair of tongs, which grasp them by the copper-driving band, which portion is not painted. The shells are now placed nose downward on the large drying shelves, which have recesses in them to accommodate the ends of the noses and cause the shell to stand in a vertical position. After being thoroughly dried, the final coat of paint is applied and the nose painted with red lead. This method of painting entails more or less handling of the shells and the engineering department have been endeavoring to devise a better method.

The first result of their work is seen in Fig. 28. A little sewing machine motor of $\frac{1}{8}$ h.p., built by the Holtzer Cabot Electric Co. of Boston and Chicago, is belt-connected to the cupped shaft, into which the nose is placed, and the shell is thus driven. The shell is inclined and the upper portion is supported by two rollers which bear against the copper-driving band. The whole is mounted on castors, and can be pushed along in front of the drying shelves and very little handling of the shells is necessary. A sufficiently long piece of

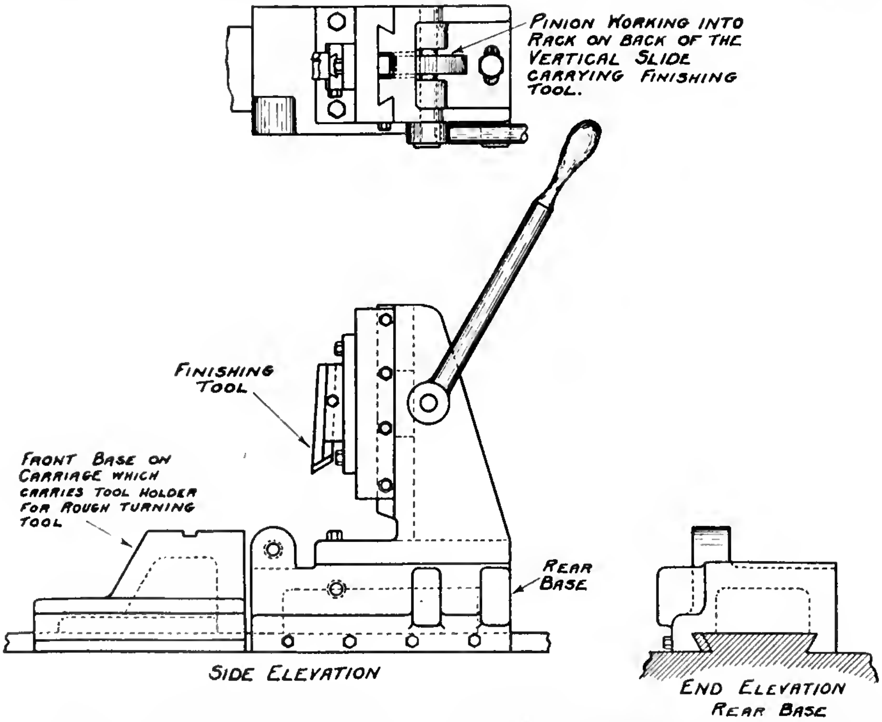

FIG. 24. DIAGRAM SHOWING METHOD OF FINISH TURNING THE COPPER BANDS.

lamp cord is furnished, and thus the machine can be used along the different rows of shelves. Experiments show the little apparatus to be very efficient, while at the same time the acme of simplicity.

After painting, the shells are placed in the drying racks by means of tongs grasping the copper bands or by hand. After being allowed to become thoroughly dry, they are packed in boxes of six and shipped.

General.

This shop is now turning out about fifteen hundred shells per day, but it is anticipated that this production will soon be increased to 2,000 shells per day, this being required in order to give the required delivery to the orders now in hand. All remuneration is made on a piecework basis where such is possible.

The lay-out of the shop is not ideal for shell making, because of the fact that the original lay-out for its peace time business purposes has been altered but little. Thus more trucking than would be required in a specially-designed plant is necessary. However, a large supply of Chapman Ball Bearing Co. and Cowan trucks are pressed into service and very little trouble or delay is experienced.

Compressed air is used freely on all machines to keep chips blown out of the chucks and from all moving parts. Loose scale and chips are removed from the shell itself by this method. Throughout the whole series of operations there does not appear to be one weak link; yet, in spite of that, the engineering department is steadily trying to improve on the various tools. Two shifts are worked—a day shift of ten hours and a night shift of thirteen hours.

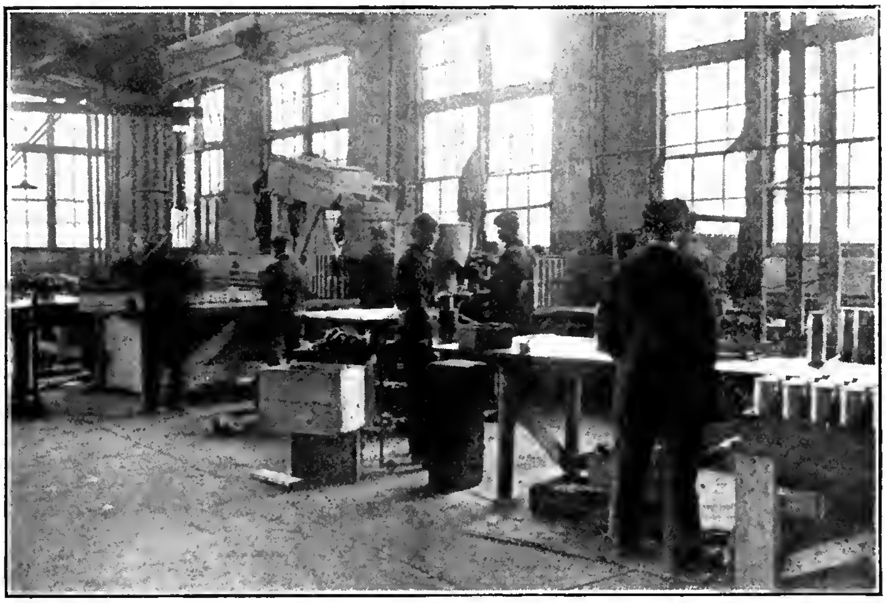

FIG. 25. SHELL ASSEMBLING DEPARTMENT.

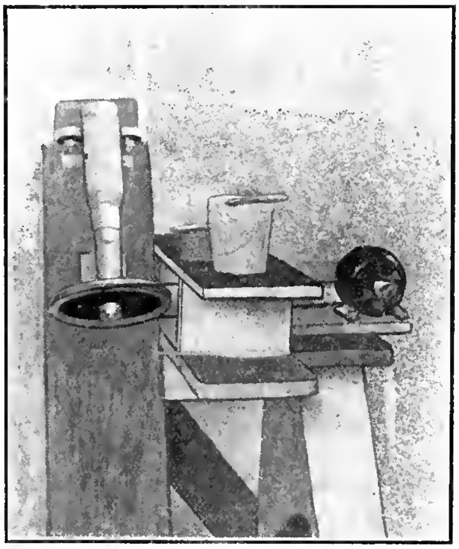

FIG. 28. PAINTING SHELLS ON A SPECIALLY CONSTRUCTED PORTABLE MACHINE.

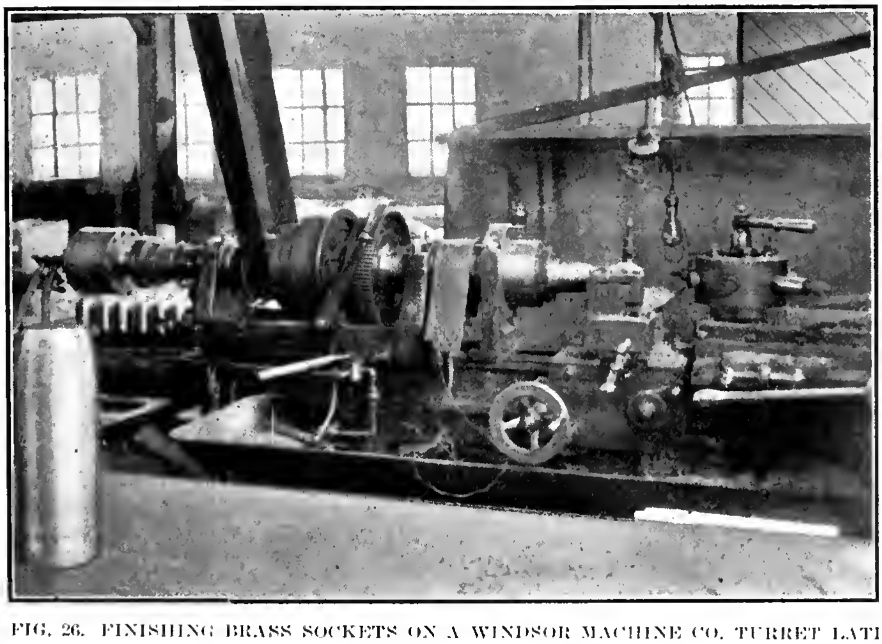

FIG. 26. FINISHING BRASS SOCKETS ON A WINDSOR MACHINE CO. TURRET LATHE.

The shop, to express in a nutshell the impression the writer received, is a "top-notcher" example of a modern industrial plant transformed quickly and at comparatively nominal expense into an arsenal. The quality of the work as well as the efficiency of the methods employed, will also compare favorably with a shop even primarily designed to manufacture this particular shell product.

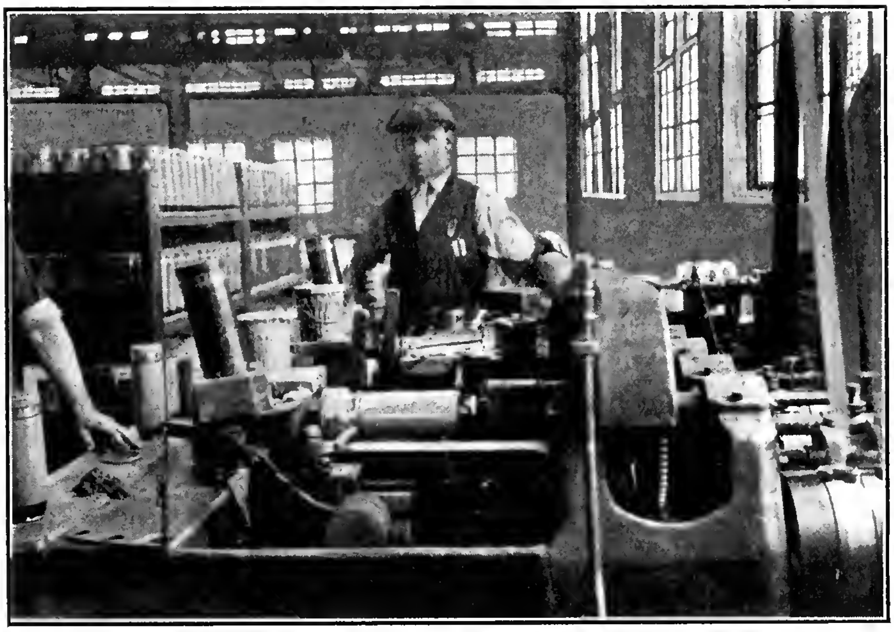

FIG. 29. PAINTING ON A STATIONARY MACHINE.

RANGE AND ACCURACY OF FIRE OF SHRAPNEL.

THE range of 3-in. shrapnel is from three to four miles, the velocity of tne shell decreasing as the flight proceeds. With a muzzle velocity of 1,700—2,000 ft. per second, flight at maximum range occupies twenty to twenty-five seconds. The velocity of the shell is then about 700—750 f.s., to which is added 250—300 f.s. bullet velocity when the bursting charge explodes. At two or three miles range, an average Q.F. 18 pdr. field gun places its shells within a zone about 200 ft. by 18 ft., and, adding to this the zone covered by the bullets, it will be seen that shrapnel gives tremendous sweeping action over a concentrated area.

Error Producing Factors.

Factors preventing absolute accuracy of fire include variable wind resistance and resistance of driving band, varying recoil jump, and slight variations in shell weight and balance. Each degree Fah. above or below 80 degs. increases or decreases the muzzle velocity about 2.5 f.s., so that fuses must be correspondingly shortened in hot weather. Considering the immense number of variables concerned, it is remarkable what accuracy of fire is actually attained.

Among the error-producing factors which are under control are eccentricity and weight of shell. On these very close limits are naturally placed, so that as little sacrifice as possible is made in the accuracy of fire. The specifications of different governments differ somewhat, but the outside and inside diameters of the shell have generally to be concentric within two mils; the weight variation in bullets may not exceed 1 drm. (1.8 grms.) per lb., the permissible variation from standard weight of the filled case being plus or minus 1 drm. (adjusted by the matrix), and the completed shell, ready for its fuse, must be within 4 grms. (2¼ drms.) of standard weight.

To attain such perfection of result in complex products to be used by the tens, or even hundreds of thousands per day, demands the greatest possible care in the manufacture of every component part, and requires an organization, sustained effort, and performance of which our shops, machines, and our operatives are proving themselves thoroughly capable. In the abstract, the wastage of material, labor, and time involved is appalling, but if the price of victory be not paid swiftly and ungrudgingly, we are condemned to the far more frightful penalty of defeat, in yet greater losses of life and treasure, and in ultimate national destruction.—Engineering Review.

BREATHING PROVISION IN SUBMARINES.

THE personnel of a submarine depend for air for breathing purposes while submerged on the free air in the boat at the time of submerging and the compressed air carried in storage flasks, which is used in freeing ballast tanks of water as well as for breathing. In the average submarine in commission today, the air contained in the boat at the time of submerging is sufficient to last officers and crew, numbering 18 men, for a period of from 9 to 12 hours.

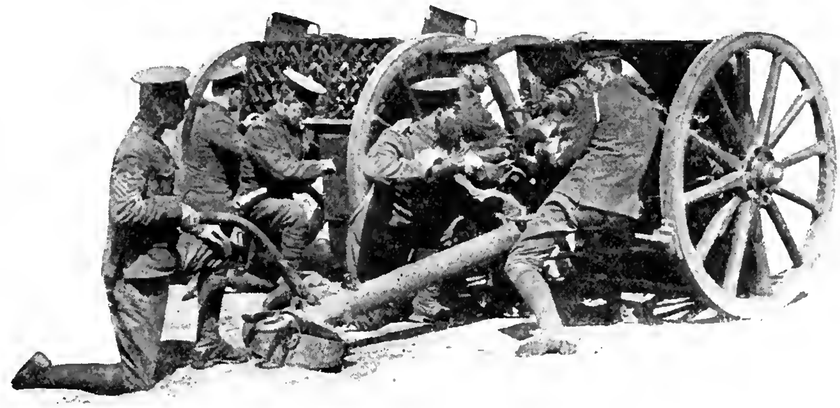
The air carried in the storage flasks is about sufficient to replenish the entire volume of air in the boat twice at atmospheric pressure, provided it is used for no other purpose. The maximum time during which all the air available can be breathed without serious effect is, therefore, from 30 to 36 hours. In computing this time, the safe amount of CO_2 that should be allowed to accumulate in the air at any time is taken at 2 per cent. Men vary, however, in their ability to withstand the effects of CO_2, the average man being able to withstand about 2½ per cent., while an exceptionally strong man can withstand as much as 5 per cent. Therefore, the time during which life can be sustained by the air in a given boat will depend somewhat upon the powers of resistance to the effects of CO_2 on the part of the personnel.

The air is maintained in condition for breathing by two methods:—First, by slowing bleeding from the main air supply into the boat and pumping air out very slowly; and, second, by allowing the air to become foul and then pumping a part of it out of the boat and replenishing it from the air flasks, at the same time maintaining a normal atmospheric pressure in the boat. The former method has been found more economical of air. The air in the boat is kept in circulation, as it has been demonstrated by experiment that air in circulation may be charged with a much greater percentage of CO_2 than still air without evil effect on the person breathing it.

SUBMARINE EFFECTIVENESS DUE TO THE TORPEDO.

THE principal offensive weapon of the submarine is the torpedo, an extremely intricate mechanism built along the lines of the submarine itself, but automatic in its action after leaving the tube from which it is fired. The torpedo is divided into four main parts—the head, air flask, afterbody, and tail. The head contains the explosive and the mechanisms to fire it. Abaft the head is the air flask. This contains the compressed air for the propelling machinery.

In the next division of the torpedo is found the depth-controlling mechanism, the air superheater, the main propelling engines, the steering engines and gyroscope, and the shafting to the propellers, as well as the rods to the rudders. The tail inside contains the gear wheels for the propellers, while on the outside are the supporting parts for the propellers, the diving rudders and the vertical rudders.



Impromptu Production of Shrapnel Shell Forgings

Staff Article

The development of our shrapnel shell industry, more especially on account of the widespread distribution of contracts among our machine shops, has of necessity increased the demand for shell forgings. The forging plant here described has been improvised accordingly, and, as will be noted, is adding a substantial quota to the meantime need. In the next few weeks, it will, however, give place to a special purpose shell forging installation.

TOWARD the latter part of last winter, the forging capacity of our Canadian shops was well below the machining capacity as far as the 18-pdr. shrapnel shell was concerned. This condition of affairs induced many firms specializing more or less in boiler-making, to investigate the feasibility of installing presses for turning out shrapnel forgings. The operations all look simple enough to the casual observer, but to one familiar with punch and die practice, the job really conveys to him the fact that there is a great deal of work connected with the proper designing and machining of shell-making punches and dies.

The steel arrives in the shop in the shape of round bar stock 3½ in. in diameter. These bars are placed in cutting-off machines and cut into billets 4 13-16 inches long. Four machines are employed in this operation, one being an Acme Machinery Co., Cleveland, Ohio, product, and the three others of John H. Hall & Co., Brantford, make. Fig. 1 shows the "Acme" machine at work. On each of the four machines two tools are used to cut off the bar. The bars are moved forward against a stop in each instance when a new cut is about to be started; thus the length of the billet to be cut off is automatically measured. Each machine is fitted with a universal chuck having four jaws.

Small nibs are left on the ends of the billets as they come from the cutting-off machines, and these are removed on a slotter manufactured by Smith, Beacock & Tannett of Leeds, England. The billets in the jig provided for this purpose are clearly shown in Fig. 2.

The billets are next carried to the furnace in which they are heated previous to the first forging operation known as piercing. This furnace is clearly shown in Fig. 3, and is a "Ferguson" product equipped with oil burners. Fig. 3 shows that side of the furnace on which the billets are fed in, three doors each equipped with counterweights being there installed.

The billets are placed in the furnace in a simple, yet rather unique way. A large piece of flat iron is laid on one of the projecting ledges in front of the doors. This flat iron is shaped like a paddle with a long blade, and a handle which makes it an easy matter to turn it on edge, is fitted to the end. Eight billets are placed on the blade of the

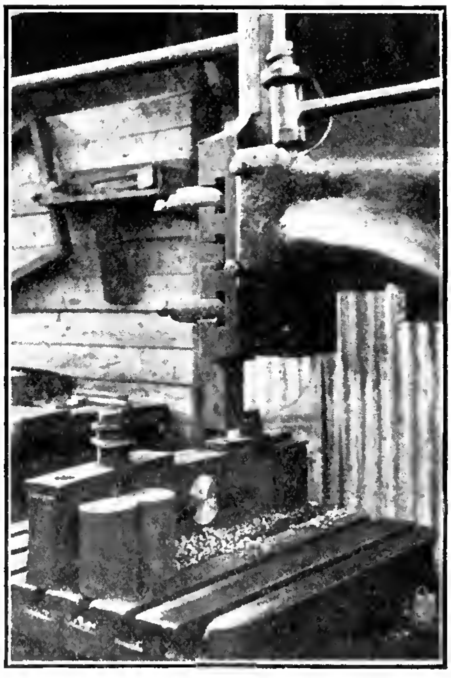


FIG. 2. SMITH, BEACOCK & TANNER SLOTTER FITTED UP TO REMOVE NIBS FROM ENDS OF BILLETS.

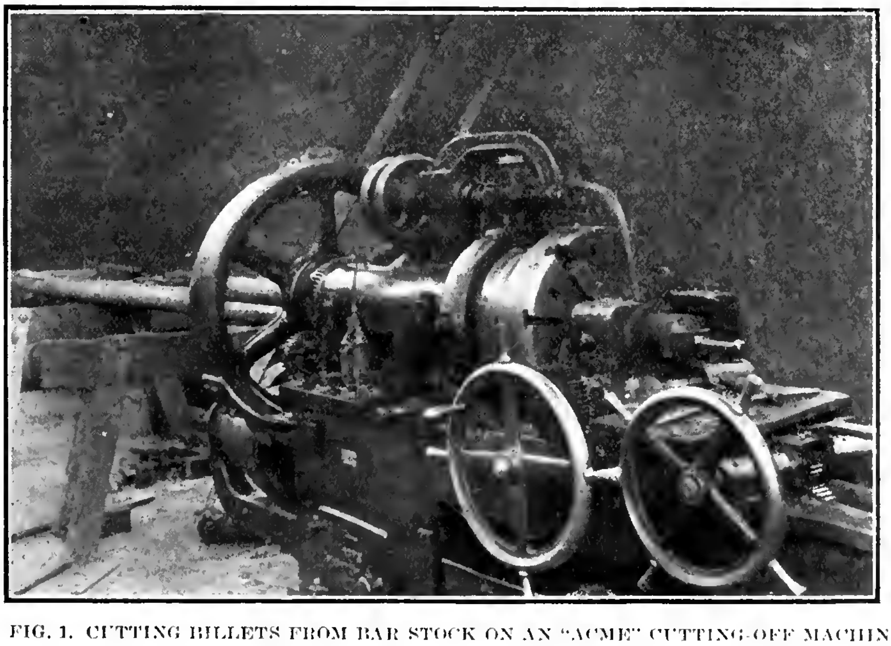

FIG. 1. CUTTING BILLETS FROM BAR STOCK ON AN "ACME" CUTTING-OFF MACHINE.

iron and the door is opened. The iron slab is pushed into the furnace and turned on edge, leaving the billets on their sides, in rows of eight in the muffle

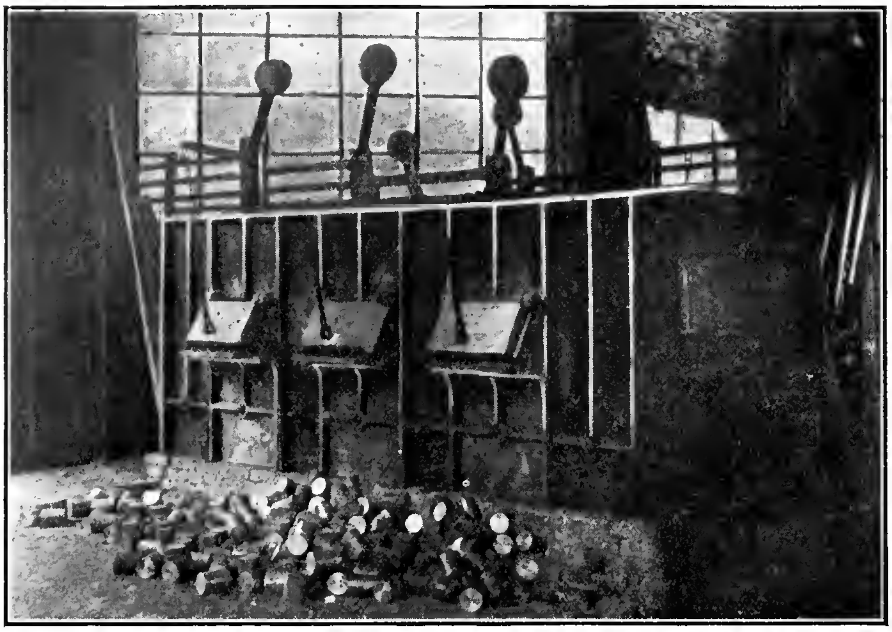

FIG. 3. OIL FURNACE FOR HEATING BILLETS PREVIOUS TO PIERCING OR FIRST OPERATION.

of the furnace. The heated billets are removed from the other side of the furnace by the three doors provided for that purpose. The billets are heated up to 1900° F. or 2000° F., and are left in the furnace for no stated length of time, being removed as required by the presses.

Piercing Operation.

The piercing operation is accomplished on an R. D. Wood hydraulic press of 350 tons capacity. The hot billets are removed from the furnace and picked up

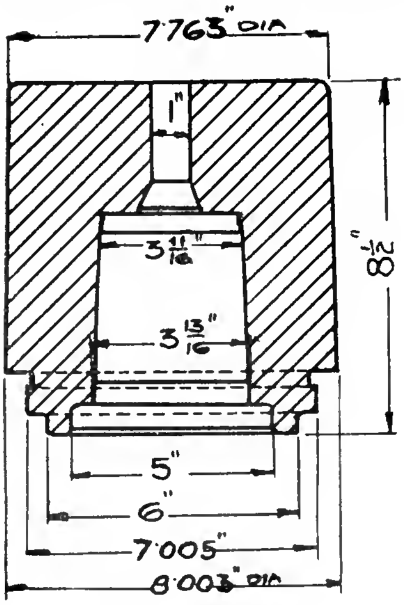

FIG. 4. PIERCING DIE.

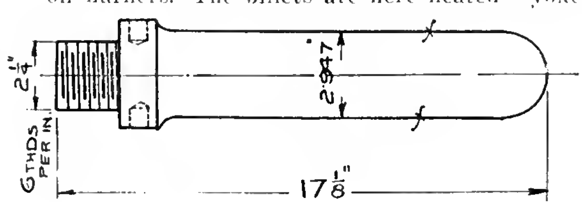
with tongs. The billets are knocked on an iron block to remove any loose scale and are placed in the dies shown in Fig. 4. The punch is shown in Fig. 5. The centering tool which guides the punch and causes it to strike the billet centrally, is shown in Fig. 6. The billet is elongated through this operation from 4 13-16 inches to about 7 inches. This press is equipped with a single spindle and is shown in Fig. 7. The billet heating furnace is seen immediately behind the press.

Reheating Furnace and Drawing Operation.

The billet is taken from the 350-ton press and passed on to the reheating furnace, shown in Fig. 8. This furnace was built by the Canadian Locomotive Co., Kingston, Ont., and is fitted with oil burners. The billets are here heated



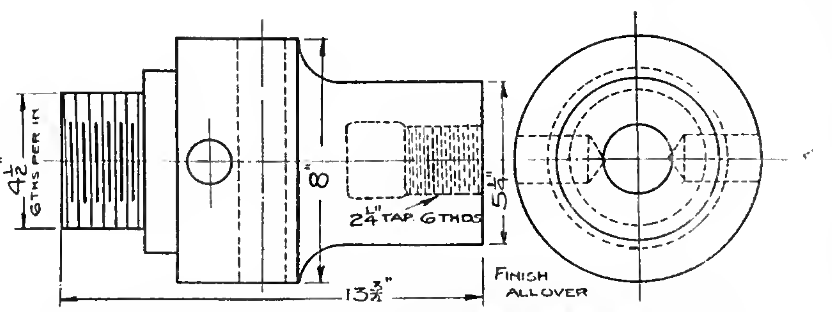


FIG. 5. FIRST OPERATION OR PIERCING PUNCH, AND HOLDER FOR SAME.

up to about 1900° F. or 2000° F. again, preparatory to being drawn out to finished length. After being heated, they are taken to the 200-ton R. D. Wood two-spindle hydraulic press for the final drawing operations. This press is shown in Fig. 9. Two quite distinct operations are performed on the press. The first is the bottom forming. The press is only allowed to complete a portion of its stroke. The punches come down in the pierced billet and the billet or forging is brought up against a bottoming die which forms the base of the forging on both the interior and exterior of the shell. This bottoming die is shown in

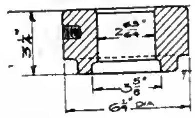

FIG. 6. CENTERING TOOL FOR GUIDING PIERCING PUNCH WHEN LATTER IS ABOUT TO PIERCE BILLET.

Fig. 10. It has still another function to perform. It stamps on the base of the shell the letter of identification belonging to the firm and the number corresponding to the carbon content of the steel. The stroke of the press is automatically stopped at the point when the punch and die have properly performed their operations. The die is placed in a small portable die holder and when the press is reversed this die and die holder are removed by means of a handle conveniently attached. The die and die holder appear in Fig. 9 on the floor in front of the press.

On the next stroke of the press, the forging which has risen with the punch is forced through the drawing dies of which there are three, the details being shown in Fig. 11. The punch details are shown in Fig. 12. The forging after being forced through the three drawing dies is stripped from the punch by a yoke of iron which is thrust into the die holder below the dies. Thus, the forging operations are completed. The forgings are piled up behind the press and are allowed to cool in the air.

The punches are in contact with the hot forgings for so long a period that they naturally become very warm. In order to cool them, water is played on the punches, being conveyed to them through a hose and through the medium of a cylindrical piece of iron. After cooling, the punches are coated liberally with a thick

mixture of black oil and graphite. The dies are also coated. This mixture is also used on the piercing press punch and dies.

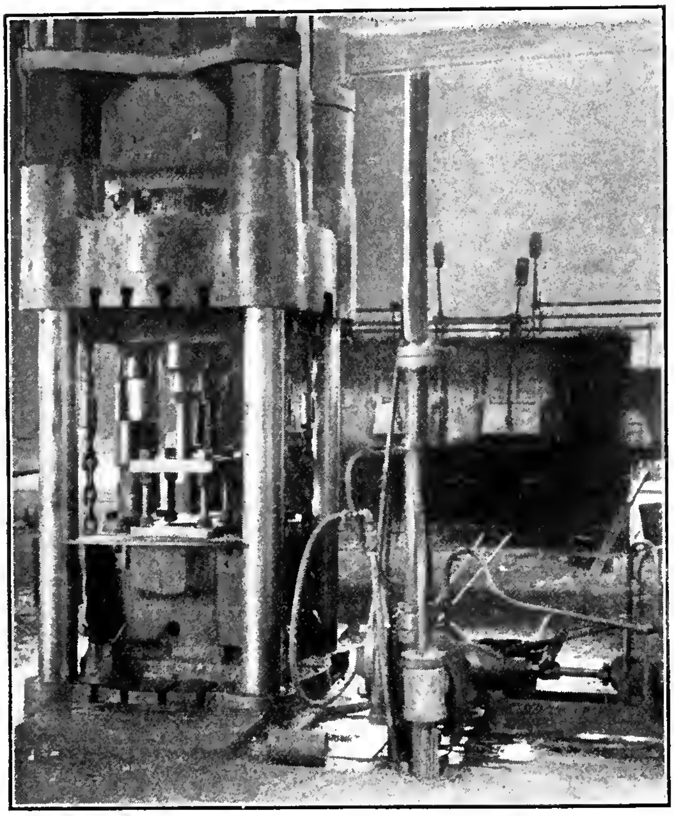

FIG. 7. R. D. WOOD 300-TON PRESS FITTED UP FOR PIERCING BILLETS.

Hydraulic Pressure Pump and Accumulator.

The presses are operated under a pressure of 1,500 pounds per square inch. The pump is a product of the Snow Steam Pump Co. of Buffalo, N.Y. At present the company are somewhat handicapped because they have had to equip so quickly all their various features. As soon, however, as delivery can be made, a new pump and accumulator of much larger capacity will be installed. Fig. 13 shows the present pump and accumulator which are working under a heavy over-load constantly.

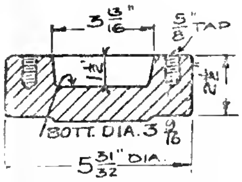

FIG. 10. BOTTOMING DIE OF 200-TON "WOOD" PRESS.

Annealing.

After coming from the drawing press the forgings are annealed. This is done in the large Ferguson oil furnace which is installed. The shells are placed in the furnace for a period of about one hour and are kept at a temperature of 1200° F. Several hundred shells can be annealed at one time in this large furnace. The shells are afterwards removed and

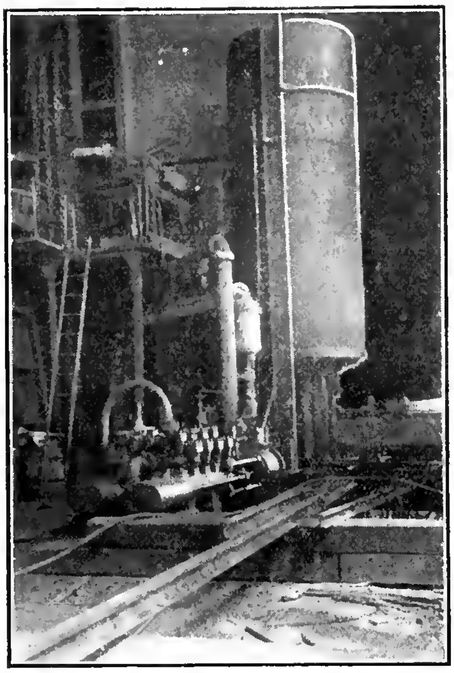

FIG. 13. SNOW STEAM PUMP AND ACCUMULATOR DELIVERING WATER TO HIGH PRESSURE MAINS AT 1,500 LBS. PER SQ. INCH.

allowed to cool slowly in the air. The heavy doors of the furnace are opened and closed by compressed air means, which makes their operation an extremely simple matter. The shells next pass on to the Government Inspection Department.

Government Inspection.

The forgings are inspected by a corps of Government Inspectors, and Fig. 14 shows them at work. The inspection can be divided into six operations.

The first operation is to stand the forgings all on end and with a portable incandescent lamp, to which is fitted a reflector, examine carefully the interior of the shell forgings for scale.

The second operation is to test the thickness and the uniformity of the walls. In Fig. 15 at A the gauge used is shown. This gauge simply calipers the walls, and the thickness is read from the gradnations above.

The third operation is to test the inside diameter. A pair of inside calipers

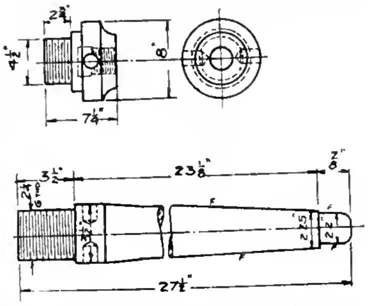

FIG. 12. DETAILS OF PUNCH AND HOLDER IN DRAWING OPERATION.

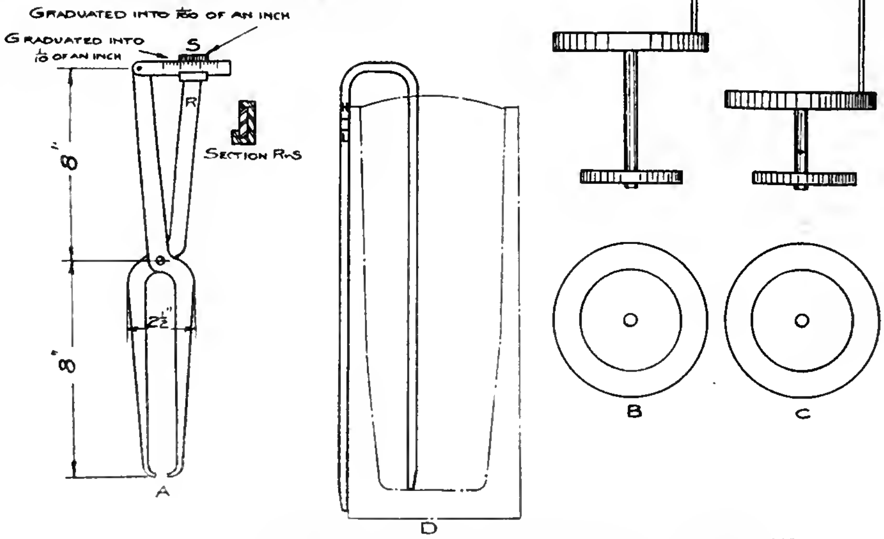

FIG. 15. GAUGES USED IN THE GOVERNMENT INSPECTION.

of more or less special design is used. The gauges B and C in Fig. 15 are placed in the forging and the diameters at these levels are tested. The gauge B brings the calipers to the top of that portion of the shell which is not machined when the shell is completed. Similarly the gauge C brings the calipers to the low level of the unfinished diameter.

The fourth operation tests the length of the shell, the gauge at D in Fig. 15 being used for this purpose. The high and low limits of length are shown on the gauge and the end of the gauge outside the forging shows if there is the required amount of metal in the base of the forging.

The fifth operation is to test the outside diameter of the forging with a snap gauge, and while doing this the inspector glances down the forging to see if it has become warped or not. It may be the right outside diameter, but if it is not straight it is not a perfect forging, so must be rejected.

The sixth and final operation of the inspectors is to mark the shell forging.

General.

Responding to the call for more forgings, this company has thrown itself into the work with the greatest of enthusiasm. The above installation shows what can be accomplished on short notice, and from this plant there are being daily received more than 2,700 forgings. By the time that this article appears in print much of the new equipment will have been received and the plant will present an entirely different appearance and will have a greatly increased capacity. However, the above description is interesting from the fact that but little of the installation was new, existing equipment being improvised by the inventive genius of the mechanical department.

CONTEMPORARY WAR ARTICLES

Embracing Information and Data Drawn from a Variety of Sources Relative to and Arising from the Prosecution of this Many-Sided European War

HIGH EXPLOSIVES.*

By L. S. Marsh.

IT is here endeavored to give briefly the methods of manufacture, uses, and, to a slight extent, the historical side of the more important explosives.

Gunpowder Discovery.

While gunpowder or ordinary black powder is not generally classified with the modern high explosives, its discovery and development have been of so much importance in the general development of all explosives that a little time may be profitably devoted to it. Black powder was probably discovered by accident, and Friar Bacon, to whom is generally ascribed the discovery, did not, therefore, really invent gunpowder.

It seems certain from such information as we have at our disposal that Friar Bacon about the year 1250 had mixed up an experimental compound of some kind, the ingredients of which among others were saltpetre and sulphur. We can imagine the effect of igniting such a mixture and if, perchance, the good Friar had rubbed some of the mixture in a mortar it is safe to assume that he was surprised at the results obtained by this simple though dangerous operation. Roger Bacon undoubtedly fulfilled the prophecy of Prometheus that, "in the latter day, a wondrous being would appear who should call forth flashes brighter than lightning and sounds louder than thunder."

Other Explosives.

Gunpowder was for years called "kraut" in Germany, and in view of its present use the other part of the word might well be added. For 500 years gunpowder remained the only explosive, and not until the year 1846 did there appear anything really new in the line of explosives. In this year Schoenbein discovered nitro-cellulose, the basis of all smokeless powders, as well as of many modern products whose uses are more in the realm of peace than of war. In the year 1799 mercury fulminate was discovered by Howard, the use of which, however, as a filler for percussion caps was not commenced until 1815. The next important step in the development of explosives was the discovery by Sobrero in the year 1847 of that exceedingly important and highly explosive compound, nitro-glycerine. Little use was made of nitro-glycerine until the invention of dynamite because of the fact that nitro-glycerine could not be handled and transported in the liquid state without very great danger. The first practical use of nitro-glycerine was made during the construction of the Hoosac Tunnel, the nitro-glycerine being transported to the work in a frozen condition.

In 1875 Nobel discovered that an explosive composed of a mixture of collodion cotton and ordinary dynamite gave greatly increased results on explosion, this same investigator having discovered dynamite as we ordinarily understand the term, in the year 1867. Blasting gelatine, discovered by Nobel in 1875, and referred to above as the mixture of collodion cotton and dynamite, is probably the most powerful explosive, weight for weight, at the present time, at least which can be used in any practical manner. Blasting gelatine owes its great explosive power to the fact that the excess of oxygen in the products of explosion of nitro-glycerine supplies the deficiency in explosion of nitro-cellulose, the carbon burning to carbon dioxide instead of partly to carbon monoxide, which additional chemical action results in the production of more heat and therefore greater volume of gas, and greatly increased force of explosion.

Divisional Classification of Explosives.

There are two general divisions in the classification of explosives, namely, explosive mixtures and explosive compounds. Explosive compounds are mechanical mixtures containing various ingredients in the form of grains of finely pulverized material, these ingredients supplying a combustible and an oxygen carrier. As an example of an explosive mixture, gunpowder is the first one which comes to mind, and is to all intents and purposes the most important of all explosive mixtures.

Explosive compounds are those substances which contain within the individual molecule the necessary substances or elements to produce an explosive wave when detonated or otherwise broken up. As an example of an explosive compound we may refer to many of the hydro-carbons and compounds of organic origin, such as the nitro compounds of ether, acetone, phenol, glycerine, cellulose, and a large number of other organic compounds.

Black Gunpowder.

Black gunpowder is one of the most common, and, from a practical standpoint, one of the most important, of all explosives, and its manufacture, while not without danger, is, however, less liable to cause trouble in the process of combining the various ingredients than some of our other forms of explosives. Black powder, as generally made, consists of potassium nitrate 75 parts, carbon in the form of charcoal 15 parts, and sulphur 10 parts. The first requisite in the manufacture of black powder is to obtain strictly pure materials, then the proper grinding and mixing of the three ingredients named above. The potassium nitrate supplies the oxygen necessary for the combustion of the carbon.

Gunpowder Manufacture.

In the manufacture of gunpowder the materials are first ground, then sifted into grains of various sizes, after which the materials are weighed out in 50-lb. lots. The mixing of these ingredients is accomplished by means of a rotating drum which is supplied with paddles travelling in an opposite direction to that of the drum itself. After the materials are thoroughly mixed in this manner they are taken to the incorporating mill which resembles the ordinary edge runner largely used in some of our older cement mills for the purpose of grinding slurry. The rollers of the incorporating mill weigh about 4 tons apiece, and the charge of mixed materials is placed on the bed of the mill to a definite depth made necessary by the fact that if the layer is less than one-fourth of an inch thick there is great danger of explosion, while if greater than one-half inch in thickness the incorporation of the ingredients will not be satisfactory.

The process of incorporating usually requires from three to four hours, and the product is known as mill cake, which is broken up into lumps of uniform size by machinery especially designed for this purpose. These lumps or particles are now made into press cake by means of hydraulic presses to further insure the complete homogeneity of the product, the press cake being again broken up and passed through sieves of different size mesh in order to produce powder grains of various sizes. The size of the powder grain is of great importance, as, upon the size of the grain depends the rapidity of combustion, and, therefore, the shattering effect of the explosion.

Gun Cotton.

Probably the most important explosive of modern times is gun cotton, this being largely used for filling shells and mines used in modern warfare. Gun cotton is probably the most easily handled

*From a paper read before the Western Society of Engineers.

and safest of all our modern explosives. In order to gain an idea of the manufacture and composition of gun cotton we must start with the substance called cellulose. Cellulose is the skeleton left of the vegetable tissue after the substances whose functions rest entirely with the vital processes of the plant have been removed by chemical treatment. The rate of propagation of the explosion in gun cotton is somewhere between 17,000 and 21,000 feet per second.

Gun Cotton Manufacture.

In the manufacture of gun cotton, old rags and waste from cotton spinning mills are generally used, which require very careful cleansing and drying before being subjected to the nitrating process. The cleansing is accomplished by treating the cotton with a strong solution of caustic potash and then washing with running water until all traces of the caustic are removed. The material thus prepared is dried and then weighed out in batches of 16 lbs. each, and placed in the nitrating machine. The nitrating machine resembles somewhat the ordinary centrifugal used in the sugar mills, and is so arranged that the acids used in nitrating may be rapidly removed and water allowed to run in, in order to commence the washing at the very earliest possible moment after the action of the acids has been completed.

During the process of nitration, the cotton increases greatly in bulk and weight, the 16 lbs. weighing, when nitrated, about 25 lbs. In order to remove all traces of acids from the nitrated cotton, washing is continued for several hours in running water, after which the nitrated cotton goes to the hydraulic press for the removal of excess water. If the gun cotton is to be stored for any great length of time, about 40 per cent. of water is left in it in order that there may be no possibility of accidental explosion, as wet gun cotton is perfectly safe under all ordinary conditions. Our modern smokeless powders are made by treating cotton in such a way as to produce what are known as colloids.

After cotton fibre has been treated with nitric acid and sulphuric acids, as in the process of nitration, it possesses a property which it did not have before nitration, and that is its solubility in certain substances, most important of which are acetone and a mixture of alcohol and ether. Gun cotton dissolved in these solvents will give a light amber-colored solution which, upon evaporation, will yield solids more or less viscous in their nature, the viscosity depending upon the amount of solvent left in the mixture. This resulting compound is called a colloid, and is the substance used in the manufacture of smokeless powder.

Smokeless Powder.

In the practical manufacture, on a large scale, of smokeless powders, nitrated cotton is run through a machine which shreds it into small particles very much resembling paper pulp as in the process of paper manufacture. Chemical control is maintained during the process of shredding and washing in order to ascertain the presence of free acids in the mass. Gun cotton must not be permitted to retain any of the acids used in the process of nitration as they would cause decomposition and consequent accidental explosion. After the gun cotton has been thoroughly shredded and resembles bread dough, it is placed in what is called a stuff chest, in the interior of which revolves an endless screw which forces the cotton out through an opening at the top.

The gun cotton as it is now prepared contains about 40 per cent. of water, and in order to remove this excess water and prepare the cotton for the colloiding process it is put through a hydraulic press and a large part of the water removed by pressure. The pressure cannot be continued sufficiently, however, to remove all the water, and alcohol is permitted to run through the top of the cylinder containing the cotton, thus taking out all of the water by solution in alcohol. Practically all of the alcohol is pressed out of the cotton, which then goes to another press and is treated with ether, thus completing the process of collodization.

The colloided cotton is passed through dies by means of an endless screw revolving in the drum, these dies being arranged with needles which give perforations in the resulting rope or rod of smokeless powder. These rods are of various diameters and are cut into sections or grains by means of bronze knives. As in the case of ordinary gunpowder, the size of the grain determines the rapidity of combustion, and, for large calibre guns, smokeless powder may be made in the form of sticks resembling walking-canes.

Nitro-Glycerine.

The manufacture of nitro-glycerine is very similar to that of gun cotton, with the exception that the substance to be nitrated is glycerine in the place of cellulose. Nitric and sulphuric acids are used for nitrating glycerine, but a very careful watch has to be kept of the process in order to prevent the occurrence of disastrous explosions due to the decomposition of the glycerine and consequent rise in temperature of the mixture. The nitrating of glycerine usually requires about one-half hour, after which the treated glycerine is run into tanks filled with water, where it sinks to the bottom, and is drawn off for further purification.

Nitro-glycerine, as such, is not used to any great extent at the present time, but is the basis of a large majority of the dynamites now on the market. Ordinary dynamite consists of some absorbent material, such as infusorial earth, otherwise known as Kieselguhr, which is permitted to absorb the nitro-glycerine, the amount of this absorption depending upon the strength of the dynamite desired. Dynamites are graded according to the percentage of nitro-glycerine which they contain, as, for example, 60 per cent. dynamite contains 60 per cent. by weight of nitro-glycerine. Some of the modern dynamites contain, in addition to nitro-glycerine, other substances which supply an excess of oxygen and thus increase the violence of the explosion.

Blasting Gelatine.

I have already mentioned the discovery of blasting gelatine, and would briefly state here that blasting gelatine consists of about 90 per cent. nitro-glycerine and 10 per cent. nitro-cellulose, the two substances being mixed by means of wooden paddles in a large tank or vat, and finally kneaded with the hands like bread dough until a mass, having a smooth, even consistency, is obtained, the resulting product resembling a jelly-like substance, soft enough to be easily cut with a knife. This mass is forced through a die as in the manufacture of smokeless powder, and the rope or cable is cut by means of a bronze knife into the desired lengths and wrapped in paraffin paper to form the completed dynamite stick.

ROYALTY AND THE RIVETER.

THE following humorous incident falls to be recorded in connection with the recent tour of inspection of our King among the Clyde shipbuilding and engineering establishments. At a particular yard the foremen were being presented, and when it came to the foreman riveter's turn, the introduction was effected in the following words:—"The foreman riveter, your Majesty, who controls the men giving most trouble at present in the shipyard." The King, with that kindliness which so won the hearts of the war workers, remarked "And I suppose you are having a rather difficult time in controllling your men just now." The foreman's reply was certainly convincing, if somewhat unexpected: "If yer Majesty had the handlin' o' them for a week ye wad ken something about it."

Lord Dewar, speaking at a recruiting meeting in Edinburgh, recently said that in the creation of her war machine, Germany had destroyed the soul of her people—a high price to pay, even for efficiency.

RECRUITING OUR MECHANICS FOR BRITAIN.

MORE or less interest has been aroused and not a few misgivings have been expressed relative to the recruiting and enlistment of our skilled mechanics for war munitions manufacture in Great Britain. In order to get the pulse of the situation thus created, and therefore keep our readers in close touch with the present and probable future outlook development, we have been in communication with a large number of our engineering and metal-working plants, all of which are engaged in shell manufacture. Such of the replies to our letter as came to hand before this issue went to press are appended herewith:

Editor Canadian Machinery,
Toronto.

Dear Sir:

In answer to your favor of the 24th ult., we think it is a mistake to encourage the transportation of skilled machinists from Canada to Great Britain to work on war munitions there. Owing to so many manufacturing plants in Canada being engaged in manufacturing war munitions, there is at the present time a decided scarcity of skilled machinists in Canada, and the policy, therefore, of taking any of them away and transporting them to Britain is, in our opinion, entirely wrong.

We do not see what advantage is to be gained by simply transferring machinists from working on war munitions in Canada to Great Britain to do the work there. We need the men here and the only possibility of the Canadian manufacturers being able to increase their output as the British Government desires is to retain all the skilled labor we have, and, in addition, to train a great many who are at present unskilled. We think the Government should be strongly urged to invite the co-operation of the British Government to stop the transportation of skilled machinists from Canada.

Yours very truly,

——————

Canadian Machinery and Mfg. News,
Toronto.

Gentlemen:

Replying to yours of June the 24th, we have lost a number of mechanics to go to Great Britain to work on war munitions, but not as many as we have lost to concerns in neighboring cities to work on their shell contracts, nor any more than we have lost to local concerns, nor yet so many as we have lost by enlistments.

While all of these losses annoy us temporarily, there is such a large number of inexperienced men available that our solution of the labor problem is to retain a sufficient number of skilled men as instructors, tool men and repair men, and to train new men as operators on the various machines. The work being so repetitive makes it less difficult to train men than for any of our regular products.

There are so many men out of work in the country it does not appear wise or necessary to complain about any who go to Great Britain to work on munitions of war, or who have the courage and patriotism to enlist in any of the contingents.

Yours truly,

——————

* * *

Canadian Machinery,
Toronto.

Gentlemen:

Replying to your favor of the 24th ult., so far we have not heard of any large number of mechanics leaving this country for Great Britain to engage in the manufacture of war munitions, etc. It is quite likely some will go, but we expect it will be more with a view to having a visit to the Old Country. Of course it would seriously affect manufacturing here in Canada if there was a very large exodus, especially with improved conditions of business, but we are of the opinion that this will not take place.

Yours truly,

——————.

* * *

Canadian Machinery & Manufacturing News:

Dear Sirs,—We beg to acknowledge receipt of your favor of the 24th inst. with reference to mechanics leaving for the other side to engage in the manufacture of munitions of war. In this connection we may state that as far as we are aware none of our employees have gone over to the other side.

Considering the number of applications which we receive from day to day from men seeking positions as mechanics and machinists, we do not anticipate that there will be any shortage in labor of this type.

Yours faithfully,

——————.

* * *

Editor, Canadian Machinery:
Toronto.

Dear Sir,—We have your favor of the 24th instant, and beg to inform you that a great many of our employees have returned to Great Britain to work on munitions of war, and some have joined the colors.

Right at the outbreak of war we lost quite a number of men from all the departments in our works, and later, when the call for machinists and other mechanics to go to Great Britain was sent out, we lost still more men from our machine shop, although at that time we were manufacturing shells for the Imperial Government. The result was that we had to go out on the street and employ men who had never seen a lathe or a machine shop, and our operations have, therefore, been seriously handicapped. We now, however, have got over most of our difficulties in this regard.

We, like other manufacturers, felt that the men employed on munitions of war in our shops would be doing quite as much service for the Empire as if they were employed in some shop in the British Isles. Of course there may be other considerations which we are not aware of and which would make their services of more value there than here, but we honestly cannot imagine what these reasons might be unless they were going to equip fully organized shops, instead of waiting in Canada until a great many of the firms which are now at this business could equip and go ahead.

If the Empire is benefited in this way, then very little complaint could be made regarding the men being drafted across the Atlantic.

Yours very truly,

——————.

* * *

Editor Canadian Machinery,
Toronto:

Dear Sir,—In answer to your letter of June 24th, requesting information as to how we have been affected by the demand for mechanics for munition work in Great Britain, we have not found any actual difficulty in maintaining our supply of labor due to this cause.

The effect of the great advertising that this subject has received seems to have been to unsettle the men, a great many

of whom although not now employed, do not show the same keen desire to obtain employment that would be the case if they had not in mind that work with exceptional wages could be obtained at any time in England.

Their impression seems to be that the wages and other financial inducements offered by the British Commission are high, even judged by present Canadian standards, and it is our opinion that if the daily press gave full publicity to the actual rates to be paid men for munition work in England, there would be little danger of there being any shortage of labor here due to emigration to England.

We shall be pleased to give you any further information which might be of help to you on this subject.

Yours truly,

——————.

RECRUITING FOR OVERSEAS CONTINGENTS.

IN view of the fact that but slow progress is being made in recruiting for additional overseas contingents, the following figures from the official census returns make it abundantly clear that resources are not lacking. We are shy on manliness, it would appear.

Census returns show that Toronto in 1911 had a male population of 107,574, whose birthplace was Canada, and a male population of 58,185 British-born. The total male population of Ontario between twenty and thirty-nine years of age in the same year was 438,295 out of 1,229,290 of all ages, or about 35 per cent. Applying this ratio, or say, 33 1-3 per cent., to Toronto figures, the result is 35,858 Canadian-born and 19,395 British-born between the ages of twenty and thirty-nine, the recruiting ages.

The census also shows that about 50 per cent. of males between these ages are married.

HARDNESS TEST OF SHRAPNEL SHELLS.

NOT the least important of the many operations which have to be performed in order to produce high quality shrapnel shells is that of "testing for hardness." A narrow strip round the body of the shell near the band groove is first polished, after which the shell is taken to the scleroscope. This apparatus consists of a vertical glass tube with an arrangement at the top for drawing up the steel hammer in the tube and a catch for holding the hammer until released. This part of the apparatus is operated by a rubber air bulb. At the back of the tube is a scale on which are figures which bear relation to the hardness of specific metals.

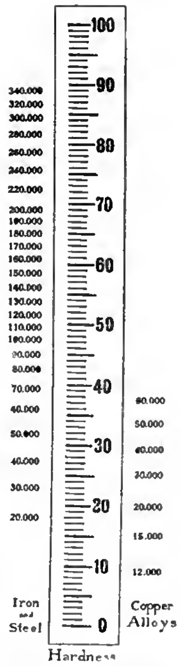
The shell is placed in a grooved block under the scleroscope and the diamond pointed steel hammer allowed to drop on the polished part of shell. The hammer rebounds and the figure at which it stops is noted by the operator. This is repeated several times, the shell being moved round each time. The hardness required of shrapnel shells must be around 45, a slight variation above or below being allowable.

The shell must not rupture at the point tested when its contained charge is exploded nor when the charge in the case is set off. Should the shell upset near the rifling band groove when being propelled out of the gun, it would of course destroy the rifling of the latter.

Experience with the scleroscope has disclosed the existence of a definite relation between the hardness and strength of metal. In determining the strength of metal, two stages are recognized: First, the elastic limit, yield point or load required to start a permanent set; second, the ultimate strength or load required to terminate permanent elongation and reduction of area in rupture.

The hardness indicated by the scleroscope is intimately related to the elastic limit, as shown by the scale cut. The elastic limit increases more rapidly than the hardness from 43 to 45, this being the minimum index of the strength value required. As an elongation of 8 per cent. in 2 inches is also called for, there must necessarily be an upper limit to the hardness. On the steel used for shrapnel which is generally about 50-point carbon, 70-point manganese, the maximum hardness should not be over 60 on the scleroscope.

TESTING SHELLS FOR HARDNESS WITH "SHORE" SCLEROSCOPE.



ELASTIC LIMITS (TENSILE) SYMBOLIZED BY THE SCLEROSCOPE HARDNESS UNITS.

EFFICIENCY.

EFFICIENCY is usually stated as the ratio of what a thing is to what it ought to be when measured by some assumed standard. When efficiency in any direction approaches 99 per cent., the amount of energy or cost required to increase it becomes entirely out of proportion to the benefits to be obtained, being governed by the well-known law of diminishing returns. It is possible, therefore, to strive too much after any one kind of efficiency. Put in another way the attainment of excessive efficiency in one direction often results in great inefficiency in another, the net combined result being low efficiency.

What is mechanically efficient may thus be commercially inefficient, and what is commercially efficient may (as money is not the only thing in the world to be desired) be totally very inefficient. The difficulty is to define total efficiency except by such indefinite phrases as "the best result at the least cost," but when it comes to defining what is the best result and what the least cost is to be measured by, then we find ourselves entangled in metaphysical reasoning of the kind that leads to nothing or may be made to lead to anything.

Machine Tool Commercial Efficiency.

To the purchaser of a machine tool, commercial efficiency is a more or less definite matter. The acquisition of a new machine tool involves the incurrence of liabilities. The interest and depreciation charges, the running expenses and the workman's wages are amounts that can be written down in figures.

Against these expenses is put the value in money of the output of the machine, and the ratio of one to the other measures the commercial efficiency of the machine from the owner's point of view. Questions of internal friction or even of personal happiness may not figure in his calculations and what to the professor or to the humanitarian might be very inefficient may be the reverse from a business point of view and vice versa.

The efficiency of a machine tool should not then be judged so much by the amount of power it wastes as by the amount of work it does, and it is quite conceivable that a machine which showed the highest possible mechanical efficiency when tested in a laboratory by a dynamometer might be most unsatisfactory from a work-producing point of view. Its handles might be in inconvenient positions, and its adjustments awkward to make; its slides might be badly proportioned and wobbly, and its frame too weak; it might be short of important movements and of other facilities for doing work quickly; and yet, in spite of all these defects, its mechanical efficiency figure might be much better than that of a machine with none of these defects. Again, the efficiency of a lathe is sometimes judged by what it will do on heavy cutting, whereas in its everyday work it may seldom or never have such work to do, and may easily be too clumsy and unhandy for the lighter work on which it is mainly employed.

The Point of View Factor.

A great deal depends on the point of view of the seeker after efficiency, and it is fortunate that, in the main, common sense is found to triumph over academic dogma. If, to take a somewhat far-fetched example, the ideal is to get rich quickly regardless of all else, then the most efficient plant, from the point of view of that ideal, may be mechanically imperfect, not durable, and unhealthy, dangerous or laborious to the operator.

If, on the other hand, the owner of the plant has the more legitimate ideal of producing the largest profit in his business that is compatible with good conditions of health, safety, convenience and wages of the workers, and with the building up of a sound and permanent business that can be handed down to future generations, then the measure of efficiency must be taken by a different scale, but in both cases the word must be understood to convey something very different from the bloodless and soulless mechanical efficiency of the schools.

The standards in such matters are set partly by the conditions under which the work is to be done, but also by the general sense of the community, and are higher now than ever before, the tendency to-day being to consider the worker as much as the work by the provision of protective devices and of conveniences for easy handling, the efficiency of which in a broad sense is universally admitted, although difficult to represent by anything of the nature of a numerical percentage.—A. H. M.

THE LATE THOMAS D. WEST.

THOMAS D. WEST, for many years one of the most widely known men in the foundry trade in the United States and a high authority on foundry practice, died at Glenville Hospital, Cleveland, Ohio, June 18, from injuries received by being struck by an automobile on the previous day. He was 64 years of age. As chairman of the board of directors of the West Steel Casting Company, Cleveland, he actively co-operated with his son, Ralph D. West, president of the company, but for several years had spent much of his time in promoting safety work in foundries and in other efforts for the benefit of foundrymen and their employees.

THE LATE THOMAS DYSON WEST.

Mr. West was born in Manchester, England. At the age of 12 he started to learn iron founding at the plant of the Portland Locomotive Company, Portland, Maine. In 1887 he organized the Thomas D. West Foundry Company, Sharpsville, Pa., now known as the Valley Mold & Iron Company, maker of ingot molds. He was vice-president and shop manager from its organization until 1909. He organized the West Steel Casting Company, Cleveland, in 1907.

Mr. West was president of the American Foundrymen's Association in 1905 and 1906, and was an honorary member of that association as well as of the Pittsburg, Philadelphia, and other associations of foundrymen. He was also a member of the American Society of Mechanical Engineers, the American Society for Testing Materials, and several other mechanical and scientific societies. He was author of "American Foundry Practice," "Molders' Text Book," "Metallurgy of Cast Iron," "The Competent Life," "Accidents: Their Cause and Remedies," and a large number of technical papers for engineering and foundrymen's associations. Two of his works have been translated into French and German.

"TNT." PRODUCTION IN CANADA.

THE report that the Minister of Militia has inspected the plant for the manufacture of trinitrotoluol, erected for the Dominion Steel Corporation, and the statement by the president of the corporation, J. H. Plummer, that the first lot of "TNT" has been completed to the satisfaction of the War Office representatives, mark an important step in the Canadian manufacture of munitions of war.

That "TNT" should be made in Canada is due to the persistent efforts of Mr. Plummer, and the soundness of his judgment in entrusting the contract for the nitration of the company's toluol to a Canadian concern is justified by the fact that, while the best English houses asked for five to six months to put up the necessary plant, the Canadian firm completed the work in two months. The benzol plant at Sydney, at which the first step in the process is taken, was erected in less than two months, and, taking the two plants together, the enterprise shows what can be accomplished in Canada when the need exists. It is a little over three months since the first contract was given to the Steel Company for toluol, and not over two months since the contract was extended to cover trinitrotoluol, and the delivery of finished "TNT" already by the Steel Company is creditable to all concerned.

It is due to Mr. Plummer that the supply of toluol available at the Algoma Steel Corporation by-product plant at Sault Ste. Marie is also to be utilized. The plant has been erected under his auspices, and, through his efforts it will be ready during the present month.

Field Guns.—These guns are, of course, made as light in scantling as possible. In order to achieve this, it is necessary to keep the maximum barrel pressure at a low figure, and, therefore, a slow-burning powder is in most cases used for the cartridge. There is a certain analogy, very slight no doubt, between what takes place in a gun at the time of discharge and what takes place in a gas engine at ignition.

THE SHELL SITUATION.

CANADA has come in for scathing criticism at the hands of Lord Curzon for her failure to deliver shells ready for the firing line as quickly as was expected, and we may be fairly certain that there exists some ground for his Lordship's remarks. In the way her natural and industrial resources have been mobilized in the defence of the Empire, Canada as a nation has no warrant to be over-proud.

Long after it became evident that the entire resources of the Empire would be needed for the prosecution of the war, a Shell Committee was appointed by the Minister of Militia. Its operations apparently were confined to distributing orders—not to obtaining orders and training and mobilizing the Canadian resources to handle them. This aspect of the situation, with its important bearing upon our exports, does not appear to have engaged the attention of the Trade and Commerce Department at Ottawa. Formally, and within the limits set by military authorities, the Shell Committee proceeded to let contracts, counting entirely upon the individual manufacturers' desire for profit as an incentive to build up a great industry over-night.

From the first there was considerable doubt as to whether Canada had the capital, plants or skilled labor necessary for the production of shells on a large scale, and it is equally clear that the British Government did not count very much on Canada in this business. The Minister of Trade and Commerce of the Dominion, through his many agents, and by virtue of the position he holds, should therefore have made it quite clear to our own military authorities and to those in London that resources in Canada for the production of munitions were very considerable, and should be utilized.

If there was need of technical advice of any kind, the Minister of Trade and Commerce should have obtained it and made it available to every machine shop in the Dominion that could be turned to account economically. There should have been no doubt left on the mind of the Director of Army Contracts in Britain as to the ability of Canadian manufacturers to produce shells.

During the first eight or nine months of the war some of our largest manufacturers on their own initiative groped their way in the production of shells with such knowledge of methods, devices and equipment as they were fortunate enough to pick up from the technical press and elsewhere. There appears to have been no concentrated effort upon the part of Government to marshall the resources of Canada for the work. Nothing of an educative or informative character seems to have been thought of. No effort was made to find out what force of skilled labor Canada could throw into the business of shell-producing.

In a crisis such as the present, it is the duty of the Government to take all the responsibility for the welfare of the nation that it can. Lloyd George wants shells, but he cannot deal with every producer individually.

Pending official readjustments now in process with the idea of developing and still further enlarging the scope of the shell industry in Canada, our manufacturers, in view of the certainty of a long drawn-out struggle, and of an insistent and increasing demand for shells, would do well to "set their houses in order"—make use of and add to their available resources—capital, plant, equipment, men and material. Patriotism demands it, and were there nothing else, that should be sufficient. There is, however, profit—that arising out of both experience and money.

Only by some such wholehearted and concerted action will we secure immunity from that criticism of incapacity of administration and inability to measure up to requirement to which we have been recently subjected.

Representative of Canadian manufacturers, their families and administrative staffs who have heeded the call of Empire for active service on our various overseas contingents.

Shrapnel Shell Manufacture

Shell Department of a General Engineering Works

Staff Article

Perhaps the most fortunate of the various manufacturing institutions in its ability to readily take over the shell business is the general engineering plant. The equipment usually requires comparatively slight alteration, and there are also at hand the type of men and scope for designing and building any necessary special apparatus at short notice.

MORE 18 pounder shrapnel shells have been made in Canada, than have any other size and denomination since the industry was started here some ten months ago, and every shop has its own system worked out and has tooled up in manner that will best utilize the equipment installed. Thus, upon entering this particular plant which carried on a general engineering business previous to the outbreak of the war and the inauguration of the industry of shell making, we are confronted with some extremely interesting tooling. The present shell shop was originally that known as the compressor shop. It is a new and up-to-date building standing somewhat apart from other and older buildings.

Primary Operations.

The shells are received in the main machine shop where they have their open ends marked off roughly to length with scratch awl gauges. They are then chucked in a "Bertram" engine lathe, carrying a universal chuck, and the open end is cut off to rough length with a parting tool. The shells are next carried over to the shell shop, the first operation there being to face the bases roughly. This is done on a vertical boring mill manufactured by H. Bickford & Co., Lakeport, N.H. To the table is bolted a jig which is capable of having twenty-four shells clamped to it. The machine is shown in Fig. 1. Both heads are utilized so as to divide the working strains over the machine more evenly. The machine is motor-driven by a 10 h.p. General Electric Co. motor. Four tools in all are used, two being attached to each head.

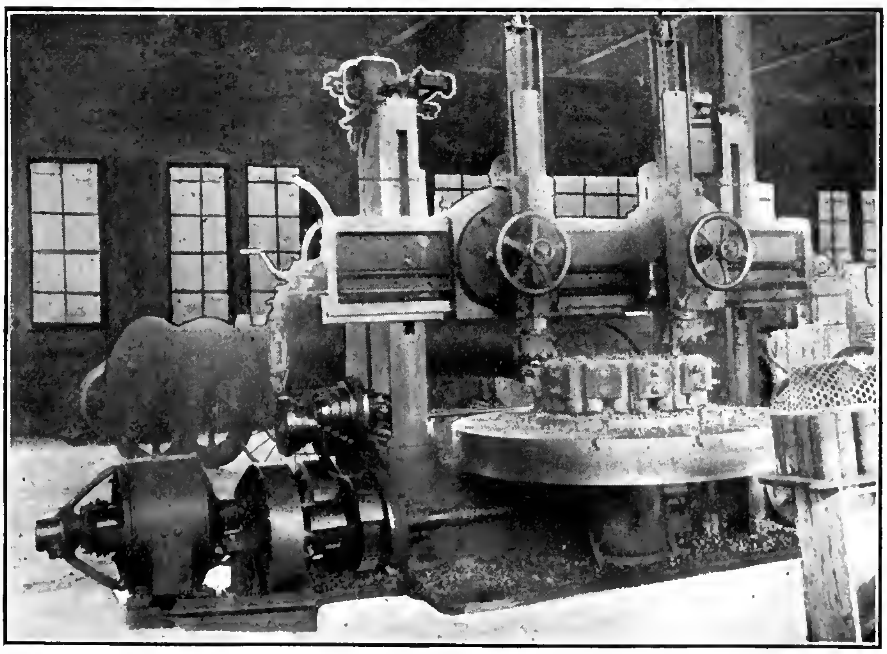

FIG. 1. FACING BACK END OF SHELLS ON AN H. BICKFORD & CO. VERTICAL BORING MILL.

Rough-Turning.

The shells next pass on to the rough turning operations. Two "Bullard" vertical boring mills are used for this. The boring mills are each fitted with a turret on which the various tools are carried, and both machines are motor driven. Fig. 2 shows one of the boring mills tooled up for the work. This machine is to all intents and purposes a vertical turret lathe. On the table is fitted an expanding chuck, the details of which are given in Fig. 3. The shell is chucked on this arbor. A fixture corresponding to the cross slide on a lathe carries several of the tools in a revolving tool holder.

A tool carried on the cross slide and ground with a wide cutting edge faces the base of the shell. A rough-turning tool, projecting from the same side of the tool holder as the facing tool is next brought up to the work and a rough taper is formed on the end of the shell to allow the rollers on the box tool following immediately to take up the work. This box tool is carried on the turret, and rough turns the shell down to a distance of $1\frac{3}{4}$ inches from the end. The following rollers prevent the shell from springing away from the tool to any extent.

For the next operation the turret is swung, and another box tool of similar design is brought into the work. This tool is carried on the turret and finish turns the shell up as far as the driving band recess.

The next operation is to form the radius on the base of the shell and to rough turn and form the driving band groove. These tools are carried on the cross slide. The shell is, however, supported by rollers from the turret during this operation. The last tool in this operation is a rough taper forming tool

carried on the cross slide. It turns the rough taper on the open end preparatory to nosing. A "Gisholt" turret lathe is also tooled up to accomplish these operations. No lubricant is used on the vertical boring mills, but, on the "Gisholt" turret lathe, a soda water compound is employed.

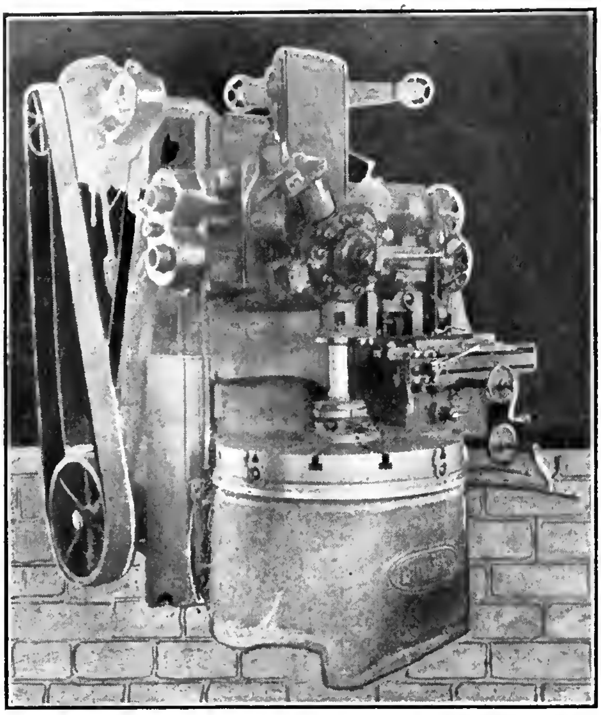

FIG. 2. "BULLARD" VERTICAL BORING MILL TOOLED-UP FOR ROUGH TURNING SHELLS.

Boring.

The boring of the shells is accomplished on two "Jones & Lamson" flat turret lathes. These are equipped with "D. E. Whitton" self-centering chucks. There are two boring bars from the turret, one carrying the roughing cutters and the other carrying the finish cutters. The latter are placed in the bars inclined a little to the horizontal —about an angle of 10 degs. to 12 degs. After these two operations are accomplished, the turret is swung again and the unfinished portion of the shell is rough turned and the nose faced. This constitutes the series of operations on the turret lathes fitted up for the boring operations. Fig. 4 shows one of the turret lathes fitted up for the boring, while Fig. 5 shows the gauges used to test the shell after boring. These gauges test the thickness of metal in the base, the distance between the bottom of the powder pocket and the diaphragm seat, and also the profile of the powder pocket and the diaphragm seat.

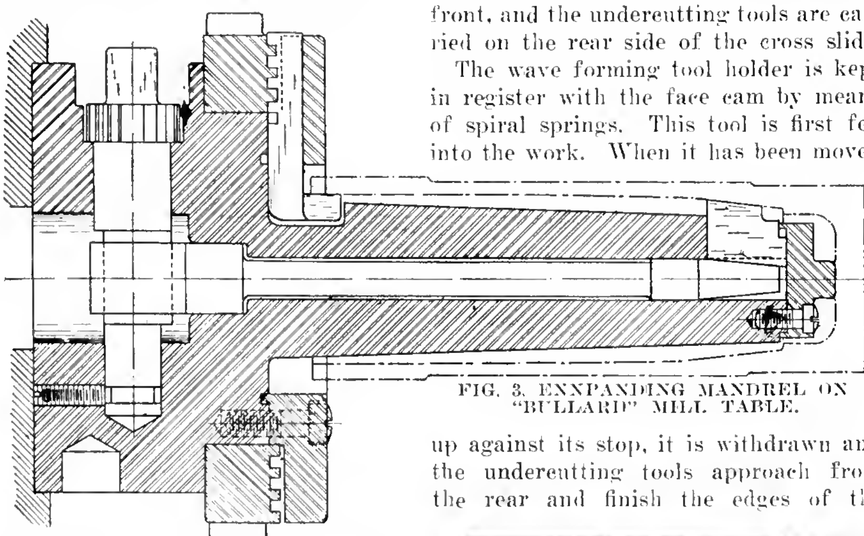

FIG. 3. EXXPANDING MANDREL ON "BULLARD" MILL TABLE.

Machining the Driving Band Recess.

Two engine lathes are tooled up to accomplish this work. One is a motor driven "C. M. C." engine lathe and the other is a "Bertram" engine lathe. Fig. 6 shows the "C. M. C." lathe. A split box chuck is attached to the face plate. The shell is chucked up against a stop A split bush is placed on the shell and the chuck closes down on this bush. On the face plate is bolted a three-point face cam, which is integral with the split chuck. The wave forming tool is carried on the cross slide of the lathe at the front, and the undercutting tools are carried on the rear side of the cross slide.

The wave forming tool holder is kept in register with the face cam by means of spiral springs. This tool is first fed into the work. When it has been moved up against its stop, it is withdrawn and the undercutting tools approach from the rear and finish the edges of the groove. These tools are fitted to small tool holders, which travel in slides at an angle to the work. In this manner the undercutting is accomplished. With the completion of this operation the groove is finished. The "Bertram" lathe is tooled up in an exactly similar manner.

Heat Treatment.

The shells are next taken to the heat-treating department. Small oil furnaces, capable of taking in seven shells at a time, are installed. The shells are heated to 1,600 degs. F., and kept at that temperature for twenty-five minutes. A small furnace, accommodating only four shells, is also used. A "Hoskins" pyrometer is employed to keep tab on the temperatures of each furnace, and can be connected to any of the furnaces in the department. Upon being removed from the hardening furnaces, the shells are placed in a large vertical cylindrical tank of seal oil, being held in a woven wire basket and lowered into the tank. The oil, of course, absorbs a great deal of heat from the shells, and in order to keep it cooled to those temperatures at which the best results are obtained, cold water coils are placed in the bottom of the tank. To further cool the oil, jets of compressed air are also requisitioned.

The shells are removed and the surplus oil is allowed to drain from them. They are then tumbled in sawdust to remove any oil that may still remain. Following this they go to the oil burning annealing furnaces where they are kept at a temperature of 500 degs. F., for ten minutes. Upon being removed from the annealing furnaces their noses are heated to about 1,400 degs. F., in a lead pot; two shells at a time being thus heated.

FIG. 4. JONES & LAMSON FLAT TURRET LATHE TOOLED UP FOR BORING SHELLS.

They are placed on a wrought iron shelf which is submerged in the molten lead.

The shells are nosed on a motor driven rivet press to which suitable dies have been fitted. Two strokes of the punch perform the operation. After being closed in, the noses are again heated to a dull red and placed in trays of powdered lime. This latter process tends to anneal the noses and remove all traces of chill due to the hot metal striking the cold nosing.

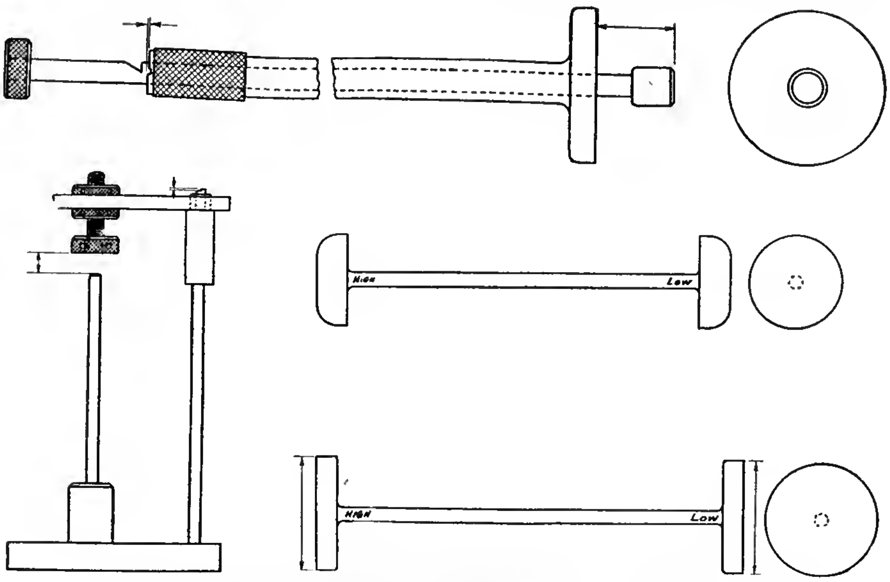

FIG. 5. GAUGES USED IN THE MACHINING OF SHRAPNEL SHELLS.

Finishing Inside of Nose.

The shells are taken back to the shell shop from the heat treating room and there the inside of the nose is machined. Three lathes are tooled up for this work. One is a London Machine Tool Co. product, the second a "Bertram" lathe, and the third a motor driven Canada Machinery Corporation lathe. The tooling on all three lathes is similar, turrets being fitted to the cross slides of the lathes. Fig. 7 shows the London Machine Tool Co., lathe fitted up with the turret on the carriage to do this work. A split chuck is screwed to the live spindle of the machine and is carried in an outer bearing. The shells are chucked against a stop. Fig. 8 gives a layout of the tools carried on the turret.

The first operation is to bore the nose, the second is to rough face it, and the third to finish face it. The nose is then tapped with a collapsible tap. Finally, the inside turning and forming tool is fed into the work. Suitable stops are fitted to all three lathes, which stops control the operations of the various tools.

Finish Turning and Grinding.

The finishing operations are done on a "Landis" grinder, but previous to the grinding operation the shells are turned and formed to within fifteen or twenty thousandths of finished size. The turning operations are accomplished on a "Bertram" lathe equipped with a special forming cam. The cross feed has been disconnected, and weights suspended from wire cables attached to the cross slide keep it in register with the forming cam. This operation is also accomplished on a Fitchburg Machine Co. "Lo-Swing" lathe, the taper attachment being modified so as to take care of the special form. The third lathe on this work is a "Bertram" engine lathe but no forming cam is attached to it, being simply used to turn the straight portion of the body.

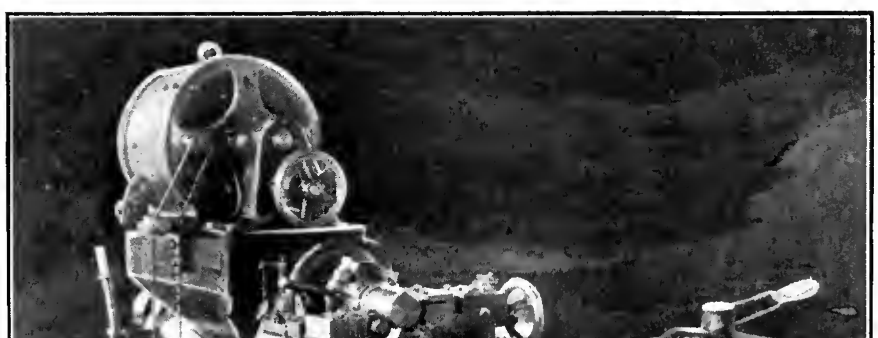

FIG. 6. CANADA MACHINERY CORPORATION MOTOR-DRIVEN ENGINE LATHE TOOLED-UP TO TURN THE COPPER DRIVING BAND RECESS.

A plug centre is screwed in the nose of the shell to enable it to be put in the lathes, the centre being on an extended shank upon which two flat sides have been ground. A driving dog is placed on the shank so that the shells are placed with their noses towards the lathe headstocks. The other end of the shell is carried in a revolving centre. On the Landis grinder a large stone dressed to the profile of the shell finishes the body and the nose at one operation. The grinder is a heavy one, being a 20 in. x 120 in. machine. A special plug centre is screwed in the nose of the shell and acts as a driver, while the other end of the shell is supported in a revolving centre. The wheel is frequently dressed to insure the production of accurate bodies and noses, and excellent production results have been obtained.

Two Canada Machinery Corporation lathes are fitted up for finish turning the shells, both being equipped with forming cams and having their cross feeds disconnected. The first lathe is driven by a motor manufactured by the Reliance Electric & Engineering Co., of Cleveland, Ohio. The face plates have been removed and the fixture shown in Fig. 10 substituted. A dog on the base end of the shell engages with the driver A and drives the shell. A plug centre in the nose of the shell is supported by the tail stock spindle. The second lathe has a universal chuck which is used to grip the base and drive the shell. This lathe in other respects is similar to the other.

The shells are next sandblasted and cleaned up, particularly so in the recess grooves and bases. They then pass on to the preliminary Government inspection.

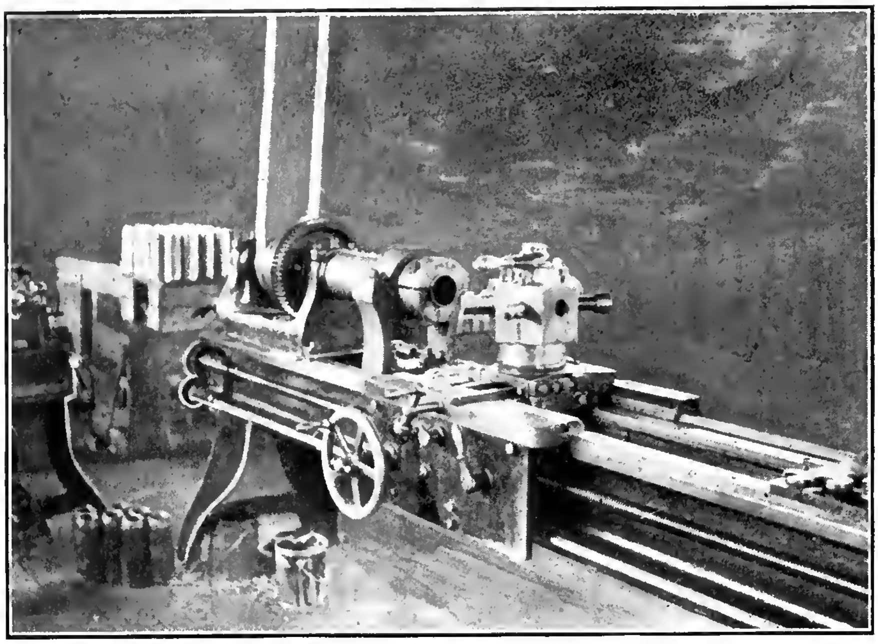

FIG. 7. LONDON MACHINE TOOL CO. ENGINE LATHE FITTED WITH SPECIAL TURRET ON CARRIAGE FOR MACHINING INSIDE OF NOSE.

Pressing on and Turning the Copper Bands.

The next operation is to press on the copper bands, this being accomplished on the pneumatic machine shown in Fig. 11. This machine was built at the works moves in against a stop. The roughing tool is carried on the cross slide and moves up against a stop. The finishing tool is carried on the rear of the lathe, and this tool comes down and shaves the band to size.

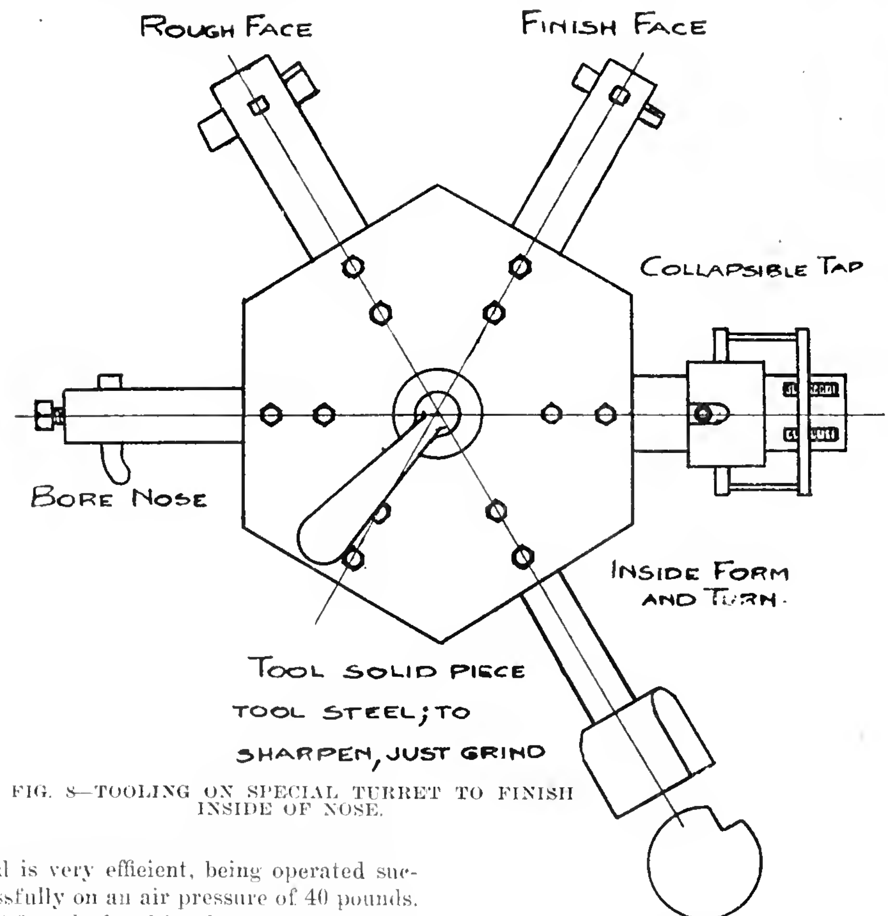

FIG. 8—TOOLING ON SPECIAL TURRET TO FINISH INSIDE OF NOSE.

and is very efficient, being operated successfully on an air pressure of 40 pounds.

After the band has been pressed on the shell, it goes to the band turning lathe shown in Fig. 12. This lathe is fitted with a universal chuck, and the shell

Assembling.

The shells now pass on to the assembling department. Here the powder cups and brass powder tubes are inserted. Running in of the shot follows. Next the molten resin is poured in, after which the shell is weighed carefully. The brass sockets are then screwed home, the thread being first coated with red lead. Next the powder tube is soldered to the socket and the shell passes on to the socket finishing lathes.

Finishing Brass Sockets.

The brass sockets are finished on an Acme Machine Tool Co. turret lathe. The base of the shell is carried in a two-jaw chuck, and the outer end is carried in a steady head as can be clearly seen in Fig. 13. The turning and forming tools which are carried on the cross slide, approach from the front and move up against a stop. The little tool which

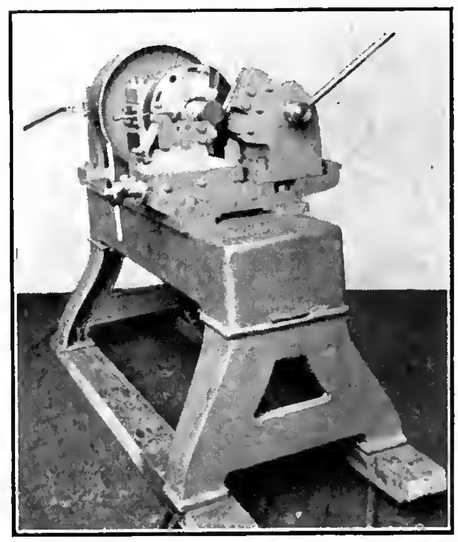

FIG. 12. JENCKES MACHINE CO. BAND TURNING LATHE.

turns down the end of the nose approaches from the rear. A spot facing tool is carried on the turret; this cleans up the projecting end of the powder tube, the central shank going into the latter. A second tool on the turret faces the bottom of the socket. This completes the socket machining operations.

Final Shop Inspection.

The shells now pass to the final shop inspection, where the sockets are tapped

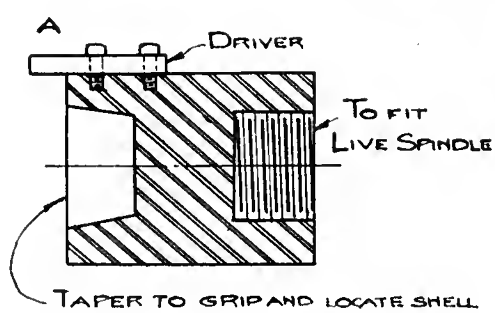

FIG. 10—FACE-PLATE ON "C.M.C." ENGINE LATHE FOR FINISH TURNING.

out, the grub screw hole tapped and also the powder tube reamed. Com-

pressed air is used to blow out dirt from the powder tube. The shells next pass to the Government inspectors who pass upon them finally.

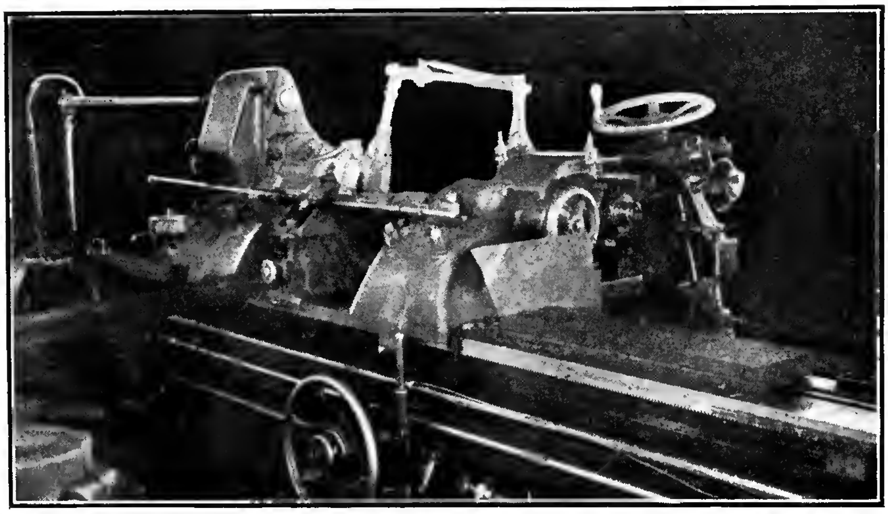

FIG. 9. "LANDIS" GRINDER FITTED UP TO GRIND THE BODY AND NOSE OF THE SHELL AT SAME TIME.

Painting.

After the shells have passed the Government inspection the little brass plugs are screwed into the socket. Small lathes are fitted up to hold the shell and revolve it for painting. The nose of the shell is supported by a square centre which fits into the brass plug and does the driving. The base is carried in a revolving centre. A priming coat of black japan is given the shells, after which they are placed on shelves to dry. Later they are replaced in the painting lathes and a finish coat of paint is applied. At the same time the noses are coated with red lead. When dry, the shells are packed in boxes of six and shipped.

General.

The shop is operated on a piece-work basis, and two shifts of men are employed. The shell output it is expected will soon reach five hundred shells per day. Excellent natural and artificial lighting is provided, and the shop is thoroughly modern and up-to-date in every respect.

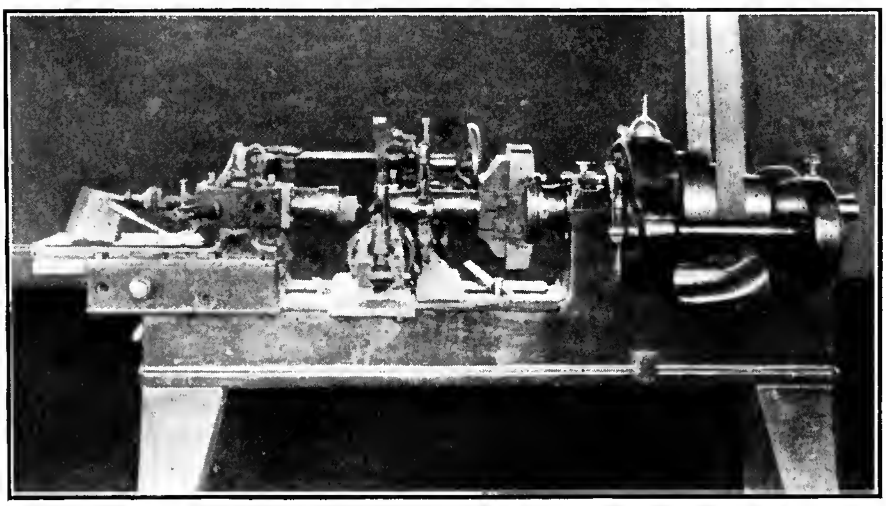

FIG. 13. TURNING BRASS SOCKETS ON AN ACME MACHINE TOOL CO. TURRET LATHE.

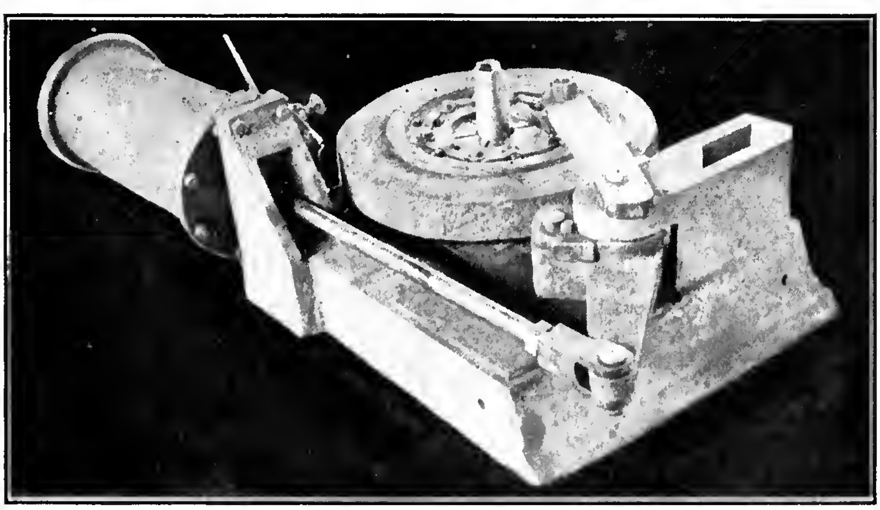

FIG. 11. JENCKES MACHINE CO. BANDING PRESS.

CARTRIDGE CASE METAL.

IN a communication to the "Manchester Guardian," a correspondent says that the tremendous price to which spelter has soared must be giving our War Department very grave concern. Continuing, the writer says: "I find that on July 31st, 1914, spelter was quoted in the region of $115 per ton and copper round $300 per ton. These prices have now advanced to around $550 for spelter and $465 for copper. In the manufacture of cartridge and shell-case metal, spelter of 99.9 per cent. purity is used, which costs about $100 per ton more than the above prices, and is exceedingly scarce at that figure.

"I have had 15 years' practical experience of metal manufacturing and hot and cold rolling, and I really do not see why the present very expensive cartridge and shell-case metal should not be displaced by hot-rolled tough copper accurately finished by the ordinary cold-rolling process. The finished cartridge and case can be drawn just as easily from copper as from the present expensive metal, and can be made much more rapidly and by more manufacturers. There are a large number of hot-rolling mills at present manufacturing copper sheet and strip whose extensive plant could be utilized.

To Deaden the Sound of War.—According to a correspondent, an interesting invention which has just been adopted by the Admiralty is known as the Mallock—Armstrong ear defender. The earpiece is no larger than the cotton wool plugs hitherto used, but contains a diaphragm of goldbeater's skin, which, while readily responsive to ordinary volumes of sound, muffles any abnormal sound. This effect is brought about by a "stop" which limits the distance through which the diaphragm can vibrate. While the ear receives readily and clearly a word of command, it is protected from the noise of the discharge of a gun.

Fire Control in Relation to Military Rifle Practice*

By Major A. C. Geddes

The last few years have witnessed a revolution in the musketry training of the British Army. A new series of ideas has been evolved and put into practice, so far as could be done in times of peace, and the new method is now undergoing its first war test. This paper gives a brief description of the work of the School of Musketry at Hythe, at which place the new ideas were worked out, and incidentally upsets our accepted ideas of rifle shooting.

THE work done during the retreat of the British Army from Mons proved conclusively that there was very little wrong with their rifle shooting, for no comparatively small force could have so fallen back in face of superior numbers if the men had not been masters of their weapon.

There is a general idea that rifle shooting is very simple; all that is necessary being to adjust the rear sight upon the weapon to suit the distance of a well-defined target, to allow for any wind that may be blowing, to aim leisurely, and to pull the trigger. This is the theory which is practised at Bisley, and those who follow it are clamoring to have it continued in its old form. The fact that this form of rifle shooting is almost useless for active service does not seem to make any difference to them.

A departure from this simple idea of firing a rifle to hit a mark must be made as soon as rapid shooting begins under service conditions, and as a result certain complications arise. For instance, it has been found by experiment that with the British rifle and Mark VI. ammunition, there is a deviation of the line of departure of the bullet from the line of the axis of the barrel, caused by the motion set up in the latter by the force of the explosion. This deviation, which is known as "jump," depends upon the nature of the charge, the muzzle velocity of the bullet, the condition of the rifle, including the bore of the barrel, the tightness of the screws holding the barrel to the stock, and whether there is a bayonet fixed or not, and with every variation in the manner in which the rifle is held.

Long Range Mark Shooting.

Therefore, on active service, the simple theory of rifle shooting is no longer true. Conditions then prevail when the rifle cannot be kept always at the same temperature, or fired so slowly that the barrel does not heat. All this at once throws doubt upon the usefulness of the expert target shot, who depends upon the perfect condition of his weapon, the accuracy of his ammunition, and the complete control under the most favorable circumstances of the breathing of the marksman and of his muscles. None of these can be depended upon with any degree of certainty while on active service.

It was proved conclusively in South Africa that great accuracy in rifle shooting at large, clearly defined targets, and at long ranges which were definitely and accurately known, is of little avail in active service, as the necessary conditions cannot be reproduced. This does not mean that great accuracy of rifle shooting is not useful at shorter ranges where all these disturbing conditions have less influence. It is laid down in the British Army training that accurate shooting at from 200 to 500 yards is of extreme importance, provided it is combined with great rapidity. Maximum rapidity of fire with individual accuracy at long ranges is, however, not worth working for, because it cannot be maintained under service conditions.

Concentrated Volley Firing.

The realization of these facts at once completely changed the training the individual soldier undergoes in the regular army. Previously efforts were made to train the men individually for long range shooting, but now they are not so trained as individual shots. Not only is it a question of barrel, ammunition and the general condition of the rifle, but there are other factors causing inaccuracy, such as barometric pressure, weather, temperature and the fact that it makes a difference whether the firing is along a horizontal line of sight or up or down from the horizontal. All these points have a serious effect on target accuracy at long ranges.

Instead, therefore, of attempting to train each man to shoot with extreme accuracy at ranges beyond 500 yards, an effort is made to use the rifles of companies or half companies as one firing machine, and to turn the stream of bullets into any area it is desired to beat with fire. This new system requires a quite different type of skill. It is first necessary to have a very highly trained firing leader who can judge distance accurately either by eye or with the aid of a range finder, and who has some way of indicating to the men who constitute his firing machine, what target he wants them to aim at.

Standardizing Rifles.

Before he can get his machine at work, although he knows how to judge distance and indicate targets to secure proper results, he has to standardize his rifles by some method which can be used in the field, and which, therefore, requires no complicated apparatus. When the rifles are thus standardized, each man can be instructed as to the range at which the backsight of his rifle is to be set to get the range desired. Rifles have been found on examination to be really ranging at 1,200 yards when the backsights were set at 1,500. Thus on service, a fire-leader must have each rifle standardized, be able to demonstrate targets, to judge distances, and to judge ground in relation to rifle firing. Many good fire-leaders were in the divisions which first went to the continent, but the casualties amongst them have been enormous.

The method of standardizing rifles is very simple. It requires an open stretch of ground and a vertical target—a barn wall or a screen or even a tree will do. Thirty yards away, the rifles are aimed at the ground line with various elevations and the point of impact marked, and from this the true range can be obtained by reference to range tables, the height above the ground being the determining point. The judging of distance is most elaborately studied.

Accuracy of Observation.

On the first day when the class arrives at Hythe to undergo instruction the men are led out to the seaside grounds, over which the school has absolute control, and asked without any previous warning to say within three minutes how many dummy soldiers are to be seen in front. On one occasion out of a squad of seven, one man saw one dummy and others various numbers, while one man saw over twenty. In reality there were fifty dummies exposed. This part of the training is to teach soldiers to observe accurately what they see.

Next it is necessary to teach the men certain standard distances first over flat ground, then over water, then over hilly ground, and then from a low point to one up a hillside; and finally from a hillside down into the valley. These standard distances are seen and re-seen until everyone is more or less familiar with them, and with the apparent sizes of dummies at these distances.

When new men become proficient in the elementary part just described, they

*From a paper read before the Canadian Society of Civil Engineers.

are given instruction of a more advanced character. First, they are taken to a hillside which commands some miles of open country and told to listen. Two or three shots are fired with blank cartridges by a man who stands up for four seconds after firing, and then disappears into the gorse or behind a wall. Each member of the class has to adjust the sights of his rifle to the range for the distance at which he estimates the man was. This is carried on until a fair standard of accuracy over the different types of ground already referred to is attained.

Judging Concealed Fire Direction.

In the next stage of instruction the firing is carried on out of sight and its direction has to be judged. After one has learned to judge the direction of firing—and that takes some men a long time to learn—the next step is to range on the nearest fold in the ground which might conceal the firers. The firer is never exposed at all, and it is extraordinary how, after training, men can accurately by sound and observation of the ground, discover the probable location of the enemy, and get his range. Once this elaborate instruction is gone through, by eye, with the instructors checking the distances accurately, men are taught the use of the range finder, but judging distance under service conditions is put first.

The fire-leader is now instructed how to indicate targets so that he can switch the whole of the fire of his machine on any point he desires. In service a target is seldom a very visible object. It may be a line of heads at a thousand yards, perhaps merely a fold in the ground, a hedge or a house, but whatever it be, if the machine composed of a company, a half company or a section is to be used properly the target must be absolutely pointed out to every man who is in the formation.

Influence of Intervening Ground.

After the fire-leader has learned to judge distances and to properly indicate targets, he has to study the effect of ground shape upon his rifle fire. Rifle fire at short ranges, especially with the modern rifle and high velocity bullet, such as used in the German and English armies, with an initial velocity of 2,400 feet a second, requires very little special sighting anywhere within a range of 600 yards, and so long as the ground is horizontal the fire is easy to control. With a rifle fired from a prone position, the trajectory up to 700 yards, is well below the head of a cavalry man and not much above the infantry, and at 600 yards or less it is well below the head of the infantry.

With these bullets and such trajectories, it is obvious that, for service work, sighting—but not aiming—hardly matters at all inside of 500, 600 or 700 yards' range because if a man lying on the ground fires at the ground line at any man approaching in the erect attitude on horseback the latter will be hit somewhere, and that enables a battle sight to be used. Of course, this is quite distinct from target shooting, for the object is to hit to kill and sighting does not alter very much unless the ground has a dip into which the enemy may sink.

At say 1,000 or 1,500 yards conditions are completely changed, because the bullet is coming down so steeply that the dangerous area is smaller, therefore, the nature of the ground is of great importance. From 600 or 700 yards outwards, then ground becomes more and more a consideration in relation to rifle fire. At a range of 2,800 yards. the culminating point of the trajectory is reached between 1,600 and 1,700 yards, the bullet then being at a height of 600 feet above the horizontal line of sight. It is this great height of trajectory at the longer ranges which is so important. A bit of ground that followed the trajectory in its curve would be a perfectly ideal field of fire because from the muzzle of the rifle to a distance of 2,800 or 3,700 yards, which may be taken as the extreme range of the modern British rifle, the whole area would be dangerous space, and nothing could advance. Such bits of ground occur only rarely, but they are to be found, and it is to make use of them that fire-leaders have to be trained.

Rifle Fire Defence.

The ground, therefore, has a great influence upon the defence of a position by rifle fire, and determines the type of position to be selected for defence. Of the stream of bullets sent out from a single machine gun or the rifles of a company, the best directed fifty per cent. furnishes a nucleus of the action of fire. Rather more than fifty per cent. of the bullets are effective from the point of view of beating ground, but not of killing the enemy.

With fairly good shots and with rifles recently tested and directed by a good fire-leader, about 75 per cent. of the bullets will fall within the really effective area. There will be a certain spreading out of the nucleus by the creation of a larger dangerous area on downward slopes. With ground which slopes upward from the line of sight, it follows that if a company is forced to occupy a position with rising ground near it, the leader cannot hope to develop any very great fire effect against the enemy while the latter are descending the slope. On the other hand, the enemy while on the top of the slope cannot develop any great fire effect against the company because their fire will of necessity be a more or less plunging one on account of the downward inclination of the line of sight, and a plunging fire gives so small a dangerous area that it is likely to do but little damage.

It is recognized with all the influences which exist to make ranging difficult, that it is practically impossible for any man, however skilful, to judge the proper range at which to set his sight. Although he may judge the distance perhaps within a hundred yards, that will not help him much if the range is 2,800 yards where there is a fall of about 137 feet in the last 100 yards of the bullet's flight. It is not only difficult to get the exact range, but also to get the barometric and temperature effect of the air. To overcome these difficulties, a device known as "combined sights" is adopted—that is, making part of the firing machine fire at one range, and part at another, say half a company at 1,400 yards and half at 1,550, which spreads the nucleus of the fire zone.

"Combined Sights" Device.

With accurate ranging, the nucleus of the beaten zone will fall within the required area, but without such accurate judging there will be no effective beating of ground where it is required, or the nucleus may only touch the edge of the required area with too thin a shower of bullets to do real damage. It is therefore frequently necessary to use combined sights, so as to get a greater searching power and depth in the zone of fire. In searching ground, the same aiming mark is used throughout one search, but the range is progressively increased or decreased, so that a strip of ground is beaten for perhaps a mile in depth and then another strip is beaten, and so on until the whole ground is searched in strips.

Similarly, sweeping may be carried out by changing the direction of fire crosswise—or searching may be combined with sweeping—so that if there are four companies in action, two are searching and the other two sweeping, two working fore and aft and two working backward and forward across the front allotted to them. In this way the greatest possible psychological effect that fire can produce is obtained. A dropping fire does not disturb men very much after the first few minutes because so few men get hit and there is so long an interval between hits that no one gets nervous, whereas, if heavy fire is brought to hear with a sudden rush on one part of the line and suddenly switched to another, each bit of the line struck by the gust of fire is not only materially damaged but the men are also correspondingly distressed, which puts their shooting out more rapidly than anything else. When men are demoralized by heavy casualties around them their shooting is likely to be very poor.

After all this long range and collective

firing practice, the training in the British army has another feature, viz., individual snap-shooting. Suppose that men are attacking a position and have fought their way forward under the command of their fire-leaders until they have reached a position of say 200 to 250 yards from the enemy, at which point they are unable to advance further because any man who stands up is immediately shot. It is at such critical stage of the attack that a special phase of the battle develops. It is the crisis of fire, and has for its object the winning of either material or psychological superiority for one side or the other, in order that one of the forces may charge home and close with the bayonet.

Rapid, Accurate Fire at Short Range.

At short range, material as well as psychological superiority is gained by putting the fear of death into every man on the other side every time he moves, and that can be done only by extraordinarily rapid shooting with extreme accuracy, so that every time an enemy's head appears around a stone, through a loophole or over a cover, it is at once greeted with a stream of bullets all around him. Once the enemy's head can be kept down in this way there is nothing to stop the bayonets—and it is with the bayonet that the decisive results can be obtained. An effort is made to get the troops so close to the enemy that they can use this rapid and accurate short range fire to which they are trained. In short range fighting the men have to act individually because there is no time or opportunity for any command. They fire whenever possible and when the fire-leader has got his men to that position and feels that they will win moral superiority he is ready to make his final plans to close with the enemy.

Such, then, are the ideas which have been the basis of training of the British regular army in the last few years. The actual course of training is of extreme interest. At the great ranges at Hythe there are thousands of dummies which can be moved with great realism in almost any direction and at almost any speed. Even dummy cavalry can appear, gallop across the plains and charge. Guns appear and gallop into position, and the whole range is really a maze of mechanical devices to secure the movement of different sets of dummies.

The Dummy Feature of Training.

One of the most interesting features there shown, is a small position definitely prepared for defence by a hundred men. In front of that position, extending for about 300 yards, is ground over which dummies are arranged to advance and attack. As a demonstration a hundred really good shots are selected and instructed to hold the position while they are attacked by the dummies, and each given 150 rounds of ammunition. The dummies begin to come forward in definite infantry attack formation from the extreme limit of the range. The attack develops and is pressed home. As a rule, the dummies are practically untouched, and the men who defend the position, these good target shots, are in a condition bordering upon physical collapse from fatigue after trying to fire 150 rounds with extreme rapidity.

The continual discharge of the rifle is very fatiguing in itself. Rapid rifle firing after 100 rounds is no joke becase the barrel gets very hot and the kick very savage. As a contrast a series of recruits from a line regiment, who have done no firing, except at short ranges, but have been carefully trained in parade and field in recognizing targets and snapping without firing, are placed under command of five good fire-leaders. One of the fire-leaders is a company commander, and the other four are section commanders. These much poorer shots, not through any virtue or merit of their own, but through the skill of the firing commanders, are able to inflict hits upon between 70 and 80 per cent. of the dummies in attack. That, of course, would not be reproduced in a real attack, because the enemy would be firing at the holders of the position, and the fact of being fired at has, with all but the most experienced veterans, a certain disturbing effect. It is, nevertheless, wonderful how little difference it makes to men after a few days.

Close Order—Effect of Rifle Fire.

The next practice for demonstration is intended to prevent mistakes in formation, and shows the effect of rifle fire upon troops in close order. A series of screen are put up to represent a battalion in quarter column, with its eight companies close together. A party of green shots led by an experienced fire-leader have to deploy into position about a mile away from the screens. Sitting amongst these screens in little metal beehives, closed against the fire, but open on the other side, are the officers to be instructed. Firing is opened under direct instructions as to range, and 100 rifles working their hardest for a minute means that about 2,000 bullets are dropped in the striking area in 60 seconds.

To sit in one of these beehives is a liberal education, for before the reports of the rifles are heard the ground begins to boil. Stones jump and smash through the screens with the whizzing of bullets, and then the noise of the firing comes, and within a minute all the screens are wrecked, the poles are smashed, and everything comes to pieces. The same experiment repeated with good shots without fire-leaders in the same circumstances, is also instructive. Usually nothing happens, the men apparently judge the distance wrongly and, breathing fast after a rapid advance are not able to hold their rifles steady on the target. It is through such practical demonstration that infantry officers and men in the British Army are trained.

General.

No attempt has been made in this paper to elaborate points in connection with the use of the rifle, but simply to indicate in a general way the lines along which the British army is trained and along which all the forces of the British Empire are asked to train themselves, although many of them have not as yet responded to that invitation.

There are still men who are in the position of leaders of troops who hold out for long-range target shooting as though it had proved to be of real value in the field, whereas it has been found in actual service to be of almost no value at all. It is excellent elementary practice, teaching a man how to handle his rifle properly and keep it steady. The British War Office has been seeking to get the competitors at Bisley to agree to a complete change in the type of competitions, introducing service conditions, and it is only because the men who are interested in "pot hunting" do not understand the more serviceable type of shooting that an agreement has not yet been reached.

Of course the war has stopped this discussion, but unfortunately it has not stopped the results of the different types of training. There are troops with the Allies who have been trained on the old theory that everyone must be a good target shot to be useful, and in the idea that the officers have comparatively little to do with the shooting; whereas the officers, n.c.o's, and squad-leaders who control the fire are really the men responsible for the shooting of the whole machine.

Kitchener and the Office Boy.—An amusing story has been going the round of the Tyne shipyards concerning the recent visit of our King, accompanied by Earl Kitchener, to certain local works. The Royal party was in the drawing office of a celebrated firm on one occasion, when the door opened somewhat noisily, and a youth entered, apparently in ignorance of the presence of the visitors. "You are not one of the draughtsmen, are you?" inquired his lordship of the newcomer. "No, sir, I am the office boy," was the reply, given with such an air of self-importance that the habitually stern face of K. of K. relaxed. Turning to the King, the War Lord gravely exclaimed, "Your Majesty, the office boy."

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

CHATTERING TAPER REAMERS.

By J. C. Klaehn.*

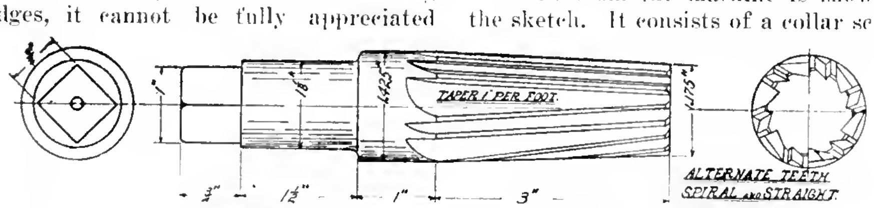
THE writer was much interested in your article in the June 17, 1915, issue of Canadian Machinery, page 519, on "Chattering Taper Reamers," from Herbert's Monthly. No doubt all that was said will be quite readily agreed to by those who have attempted to produce large numbers of reamed taper holes, which had to be perfectly smooth and accurate.

Recently the writer had a large quantity of taper holes to be reamed in brass castings, which were used as quick-make-and-break couplings on a compressed air system. These couplings had to be interchangeable, thus grinding to fit in pairs was out of the question.

From previous experience with the standard taper reamer, I knew that it would not do very satisfactory work, and, if possible, I wished to use power for operating the reamers, as considerable material had to be removed. The accompanying sketch shows the reamer we adopted for this work.

You will note that spacing of the teeth is quite coarse, being quite reverse to the usual practice, but quite necessary for rapid removal of stock.

The main feature of the design of this reamer is in the alternate straight and spiral or "backward" teeth. This prevents the reamer from "hogging in," and permits power to be used to drive it. The holes that these reamers produce are as smooth as can be desired, and unless a person had actually tried one of them into a reamed hole by hand, and felt the velvety action of its cutting edges, it cannot be fully appreciated that for a taper reamer, alternate straight and "backward" spiral cut teeth certainly seem to be the correct design.



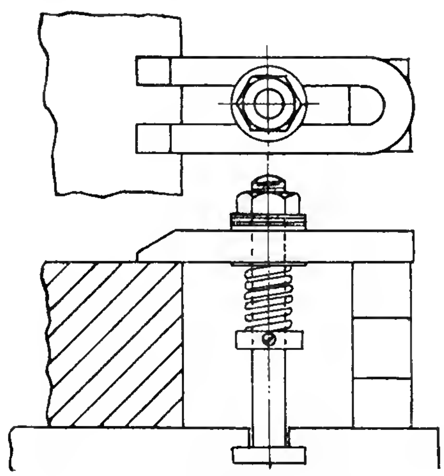
LARGE SIZE "B. & S." TAPER COUPLING REAMER.

*Master Mechanic, Can. Consolidated Rubber Co., Berlin, Ont.

A STRADDLE-CLAMP SUPPORT.

By J. E. Cooley.

ON planers, millers, and other machines where straddle-clamps are used to strap down work, a great deal of time is lost through what might be called a "wasteful method" in handling these tools. Where several of these clamps are used together, and each one is removed from the bolt and work and thrown on the floor or dropped down somewhere after an operation is completed, it is readily seen how wasteful this proceeding is. There is seldom any need to remove the straddle-clamp entirely away from the bolt, or let it even drop down, in order to remove the work from the machine. It is only necessary to provide some means to keep the clamp upheld, so that it can be drawn back sufficient to clear the work.



COLLAR AND SPRING FOR STRADDLE CLAMP.

A useful time-saving suggestion by which a straddle-clamp can be kept in position while work is being placed or removed from the machine is shown in the sketch. It consists of a collar screwed on the bolt a suitable distance below the clamp, on top of which is placed a spring and washer as shown. It is readily seen that when the nut is unfastened, the spring causes the clamp to lift up, so that it can be drawn back from the work.

One length of spring can be used for different lengths of bolts, it being only necessary to set the collar so that the spring will have a slight tension under the clamp after the nut is unloosened.

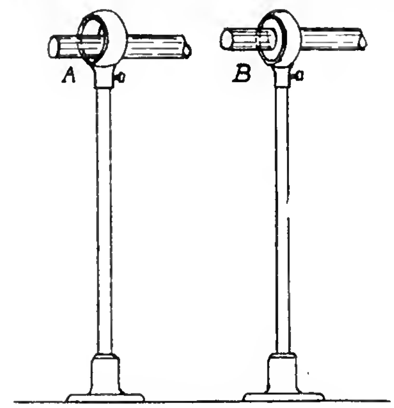
UNNECESSARY NOISE IN MACHINE SHOPS.

By E. C.

A GREAT deal of the noise made in machine shops is unnecessary. In order to produce good work, and in order that workmen shall not have their attention attracted away from same, it is important to eliminate as much as possible all unnecessary noise. While all noise cannot be entirely done away with, it is possible to reconstruct some of the means that produce it so that the sounds will be considerably lessened.

Attention is called to the unnecessary noise made in having bar-stock run loosely in the upright supports that are fastened to the floor near the ends of screw machines and turret lathes. Everyone is familiar with the rattling and banging noise produced, especially when the speeds are changed or reversed, as required in running a die off a thread.

This noise is caused by using only one size stock-holder, in order to take in all the different diameters of stock in one machine. An example of this is shown in the illustration at A. If separate stock-holders are used with holes of the same diameter as the bar-stock, as suggested at B, this noise would be greatly reduced. The holder is fastened to the rod by means of a set screw. Several of these holders could be made up and marked, and kept together in a box always ready for use.



LOOSE RUNNING BAR STOCK.

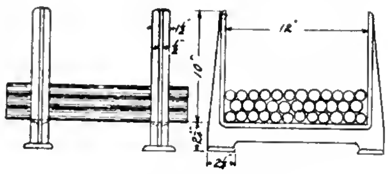
SHAFT RACKS.

By C. James.

WHEN piling small shafts on a work bench the general method is to stack them up pyramid fashion, supporting them on the sides by means of nails or pointed rods driven into the bench. This method is not always dependable, as the

nails or rods often give way, letting down the shafts with a great noise and confusion. Another objection is that more space is taken up than really necessary.

In the enclosed drawing is shown a neat and reliable arrangement for holding a considerable number of shafts in a limited space. It consists of two light yet substantial cast iron racks, that are



SHAFT RACKS.

"stood up" near each other on the work bench, the shafts being placed across them as shown.

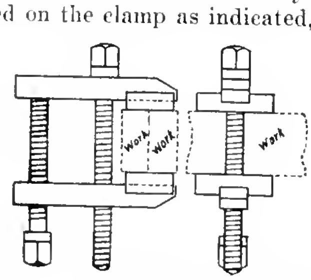
The racks as seen in the drawing are made up to hold 100 shafts of 1-in. diameter in a space of 10 in. by 12 in.

GROOVED BLOCKS FOR HOLDING WORK PARALLEL.

By J. Hartford.

IN making a jig or doing any accurate tooling, it is sometimes necessary to hold two pieces of work together parallel for the purpose of drilling or filing them, etc. For this means two steel blocks are placed against the work and fastened on with a parallel clamp.

In manipulating the blocks, they often slip away and fall to the floor, or they are not placed satisfactorily in the clamp after the screws have been drawn up. In the illustration is shown a useful "kink" that may be of interest to machinists. It consists of cutting a groove in the blocks so that they can be slipped on the clamp as indicated, thereby keeping them from falling from the clamp, and maintaining them in an upright position when the screws are tightened.

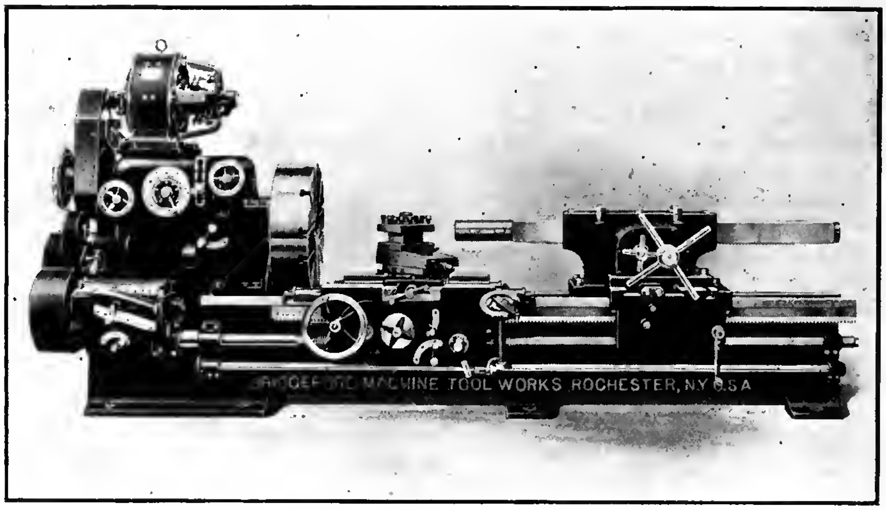


GROOVED BLOCKS FOR HOLDING WORK PARALLEL.

TURNING AND BORING LATHE FOR LARGE SHELLS.

IN order to meet the demand for machinery for the rapid production, both in turning and boring of large shells, the Bridgeford Machine Tool Works of Rochester, N.Y., have taken their 32-in. heavy pattern triple-geared head engine lathe and arranged it with devices that permit of maximum production up to the limit of the best high-speed steels. The lathe is up-to-the-minute in design, is a powerful, well-built tool, and, on a 32-in. diameter, delivers a pulling power of approximately 17,800 lbs. at the tool.

A power-fed tail block of massive construction can be supplied, which makes the boring of large shells a simple and rapid operation. The bar, which is $5\frac{1}{2}$ in. diameter, and bored and reamed for No. 7 Morse taper, is arranged on a swivel so that either straight or taper holes can be bored without using the taper attachment. The power for operating the bar is taken from the lead screw and transmitted to the bar through gearing. In addition to the power feed, there is an arrangement whereby the bar can be traversed by hand, either slow or fast, as desired by the operator. The large handwheel has two positions—one for fast movement, and the other through back gears. The small handwheel is for engaging or disengaging the power feed. There is cross adjustment for the tail block, also lateral adjustment along the bed. A four tool steel turret on the compound is of great assistance in the rapid and economical handling of the work.



TURNING AND BORING LATHE FOR LARGE SHELLS.

The lathe shown is driven by a 18 h.p. Westinghouse variable-speed motor, and controlled from the carriage by the use of a Westinghouse drum-type controller, which is placed on the rear of the frame. This enables the operator to control the motor from the carriage and change from slow to fast speed or vice versa, without leaving his position at the carriage. Without a motor the head block gives fifteen mechanical speed changes in geometric progression, but when the lathe is equipped with variable-speed motor drive, these fifteen speeds are multiplied by as many points as there are on the controller. The quick change gear box enables the operator to obtain instantly any desired feed.

A number of firms with these lathes in operation have, we understand, equipped them with side turning or full swing rests, and, when so equipped, they are able to take care of large shells to the best possible advantage.

OIL IN MOTOR WINDINGS.

By A. F. Adams.

ON a 400 h.p. induction motor we have had considerable trouble with oil getting into the stator windings. The oil apparently worked out around the plugs, inserted in the bottom of the oil well for draining the bearings, and also around the connection, where the gauge glass is placed.

Several times the plugs had been taken out and cleaned, and, as the threads in the castings were in good condition, also those on the plugs and gauge glass connections, they were replaced. Each time that this was done, however, the leakage seemed worse, drops of oil would form on the bottom of the bearing and on the outside, and, due to the current of air which was generated by the fans of the rotor, a portion of the drop of oil would be deposited on the windings.

As something had to be done, we scraped the paint off of the casting where the plug and gauge connections were and found our trouble. A portion of the casting seemed to be porous, and this was where our oil was coming from and not from the drain plug and gauge connection as had been supposed.

We successfully stopped the trouble by putting a piece of condenser tube packing around the plug and leading it to the floor. All of the oil goes down the string, and the windings are perfectly dry. Any piece of soft cord will answer the same purpose.

VAULT FEATURE, DOMINION BANK BUILDING, TORONTO

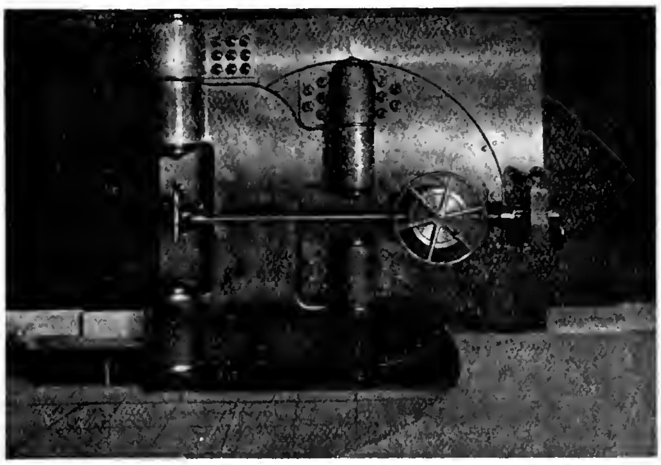
NOT the least attractive feature of the many such to be formed in the design construction, equipment and appointments of the new Dominion Bank situated on the south-east corner of King and Yonge Streets, Toronto, is the great vault, admitted to be the largest as well as the most complete in Canada. The approach is by the broad marble stairway leading from the savings bank department down to the public space separated from the vault lobby by a massive steel grille with bars one and one-half inches thick, spaced four inches on centres, and reaching from the floor to ceiling. The vault is erected entirely separate from the building construction, and is approximately 33 feet square by 25 feet high; divided into two stories, the upper or safe deposit vault, the lower or treasury vault.

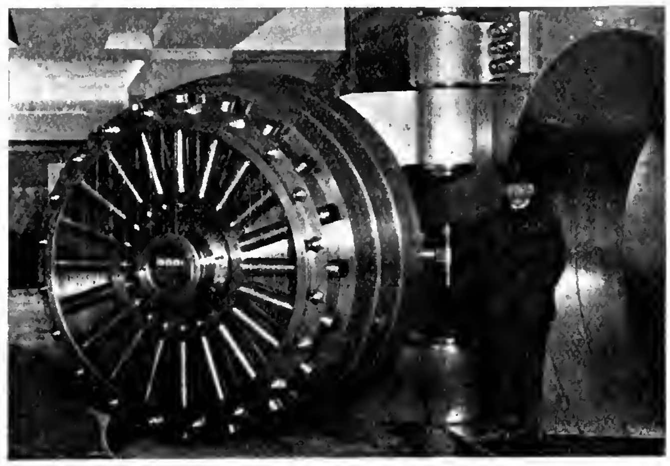
Protective Devices

Surrounding the vault is a patrol passage 3 feet in width. At the corners are placed heavy silvered glass mirrors, full depth, and set at such an angle as to permit of free observation on all sides; while similar arrangements have been made above and below, so that no exposed surface escapes the attention of the guard. Lights with silvered reflectors are arranged by means of removable parts so that the entire length of the observation space is well illuminated. Even the bottom of the vault is constructed in such a manner as to remove all possibilty of tunneling. Upon the solid rock-bed, 18 inch steel beams encased in concrete form a series of piers which support the vault, and at the same time permit an unobstructed view of all open space beneath.

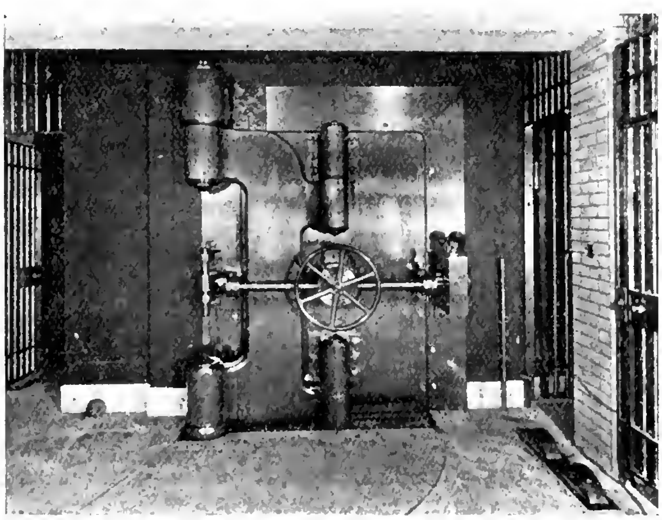
Directly over the observation tunnels just mentioned is a 28 inch floor, the construction of which consist of reinforced concrete, closely staggered iron grillage, $2\frac{1}{2}$ inch steel lining, and tile laid upon a cement base. The walls also are similar in thickness to the floor, built up of $2\frac{1}{2}$ inches of shock and drill-proof steel surrounded by 2 feet of rock concrete. This concrete is made impervious to fire, shocks and acid applications by having two rows of heavy steel beams embedded within. The entire outside surface of laminated lining is waterproofed by two layers of heavy tar paper with applications of hot tar on both sides.

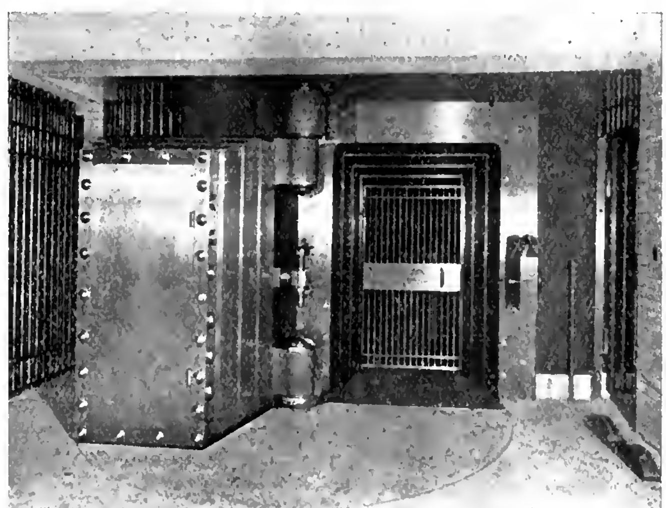
To enter the safe deposit vault it is necessary to pass through one of the





TWO VIEWS OF CIRCULAR DOOR TO SAFETY VAULT, DOMINION BANK HEAD OFFICE BUILDING, TORONTO





TWO VIEWS OF ENTRANCE DOOR TO TREASURY VAULT, DOMINION BANK HEAD OFFICE BUILDING, TORONTO.

largest and heaviest doors ever built. It is circular in shape, $2\frac{1}{2}$ feet thick, weighs more than 30 tons, and has a clear opening of 7 feet 6 inches in diameter. The door guarding the treasury vault below is of the same thickness and construction, but rectangular in shape.

The doors are of composite construction, the outer half formed of low steel castings containing 10 inches of concrete; interlaced refractory steel members $1\frac{1}{2}$ inches in diameter, by 4 inches on centres; and an outer burner proof metallic section. The inner half is built up of seven parts each of 2 inch thickness firmly welded together; three layers of five-ply chrome steel plates; four layers of low steel and solid cast steel bolt frames. With the exception of two narrow rebates, there is no short stepping and no customary tongues and grooves.

Lock Mechanisms

A feature of unusual interest is the locating of the combination locks and bolt-throwing mechanism on the door jambs and the time locks upon the doors proper. The arrangement necessitates the putting of holes through both the jamb and the door in order to reach the dogging devices in burglar operations and provides doors solid and without spindle holes. All locks and bolt-throwing mechanism are covered with heavy steel plates, while the combination dial is in shape of a steel cylinder disappearing angle-wise in the top of the front pressure housings. The front end is provided with an oval glass window, behind which appears an electrically illustrated dial with two revolving pointers which are connected with operating knobs located on the side of the housing, used to set the combinations of the locks. The device is not only one of convenience, as the cylinder is located upon a normal line of vision, but absolutely prevents any unauthorized observation of the setting up of the combination numbers.

The doors are hung upon massive steel crane hinges provided with ball and roller bearings and so carefully balanced that they are easily manipulated. They are steam tight and locked with a train of twenty holding bolts, $4\frac{1}{2}$ inches in diameter. The bolt work is covered with sections of French plate glass, at the centre of which is a circular glass door 15 inches in diameter. The outside ring of glass is one piece without radial frames, set with a grey invisible packing.

A special foundation of concrete has been set in front of the entrances for the support of the mechanism, whereby sections of the floor are dropped by the use of a hand lever to permit the opening and closing of the doors and then raised and locked in position to complete the floor levels.

Electric protection has been installed so that in case any attempt has been made to drill through the walls or doors, or should the doors be opened in any unauthorized way, three large gongs sound an alarm, one being located upon the exterior and two upon the interior.

Safety Deposit Vault Equipment

The safety deposit vault is equipped with more than a thousand boxes of various sizes, finished in polished steel, locked with the latest interchangeable key locks, and provided with an enamelled bond drawer. The vault has a polished steel grille and gate located directly within the main vault entrance. The floor is tiled with marble slabs, the joints being "struck" with monel metal bars. The walls and ceilings are panelled with steel plates and bars, and the lighting is furnished by a double system of electric equipment so arranged that the vault cannot be thrown into darkness by anyone except the proper officials.

Within the vault is a telephone which allows a means of outside communication by any person accidentally locked in at night time. If such an accident should occur the prisoner will find a pair of lights burning and a card of instructions advising whom to call and how to release the time lock devices, after which the combinations can be operated. Large volumes of fresh air are constantly delivered into the vault, the circulation of which is augmented by fans.—Cuts Courtesy of "Construction."

SEVEN MISTAKES OF LIFE.

Here is an American editor's enumeration of the seven mistakes of life:

1—The delusion that individual advancement is made by crushing others down.

2—The tendency to worry about things that cannot be changed or corrected.

3—Insisting that a thing is impossible because we ourselves cannot accomplish it.

4—Attempting to compel other men to believe and live as we do.

5—Failure to refine the mind by acquiring the habit of reading good literature.

6—Refusing to set aside trivial preferences in order that important things may be accomplished.

7—The failure to establish the habit of saving money.

THE WAR A TEST OF ENGINEERING SKILL AND CAPACITY.

WE are now into the twelfth month of the war and evidences are not lacking that its duration will be at least as long again. A feature of it, however, that seems to have been given little consideration relates to the part our Empire has played and is still playing by virtue of its having become one of the combatants.

In submitting the view, that, long ere this, Germany would have over-run the whole of Europe and have become a menace to world freedom, but for British intervention on behalf of the latter, expression is given to the thoughts and ideas of all who have followed the course of events in the various theatres of conflict since last August. Too sanguine expectations, seem, however, to have been formed as a result of our entry into the conflict—in a word, too much seems to have been taken for granted in the matter of our preparedness to make a swift and effective onslaught on our enemy and all too little was known of his highly developed fighting machine, its engineering supplement and mainstay.

When the inside history of the war comes to be written, it will be found that resourcefulness and deeds of valor or far-flung battlefields—of the type and nature chronicled in other conflicts, sea and land, may have to give pride of place for the first time to engineering expertness, ingenuity and constructive ability. In a word, the requirements of any combatant nation are, if success is to be attained, that the industries of that nation, and particularly those relating to engineering and metal-working be enlisted and mobilized for service. Mobilization of industry did not materialize in Britain with that of her standing army and her fleet, although now it is realized that such a step should have been taken. The man as in the past was reckoned to still have implanted in his nature grit superior to that of any adversary and to be at least a match.

Among other things these months of war have taught us, however, is that individual men in even overwhelming numbers are only of value when supported by the products of our workshops and factories. We need, it is true, all the men we can get, and we want a great many more to offer themselves; incidentally this is a particularly pressing matter with us to-day in Canada. We need more than men, however, we need engines and munitions of war, but as in the case of the Motherland, we have gone into the manufacture of these in that more or less spontaneous, unsystematic manner that marks our race.

As has been said, there was no Imperial command to put every lathe, tool and forge at the service of Empire. We simply have taken advantage of the opportunities afforded of Government work, realizing that thereby we were helping out in the task of suduing Germany, and incidentally helping ourselves. We have been manufacturing shells and having had several months practical experience of the work, we had got to the stage at which not a little pardonable pride was being taken in our achievement, but our shell products, although as called for, are incomplete for service. We are now asked to make them so, it only being realized at this late day that shipping empty shells either to Britain or France is a clumsy, uneconomical and unbusinesslike proceeding.

Compared with our shell forging and machining plants, those equipped for adding the "fixed ammunition," are away less than a handful. Wherever the blame for the present state of affairs may be placed, much unnecessary heart-burning and confusion is likely to result in our shell shops. Sufficient enterprise should have been shown by our Department of Trade and Commerce to make suggestion to the British War Office that our Canadian plants were both equal to the task and were prepared to furnish shells ready for the gun batteries.

Canada would have been unanimously at its back if it had demanded from Lord Kitchener why orders for millions of completed shells should not be given to our manufacturers. If Schwab, with the United States Consular service at his back, could sell to the British War Department, why could not Foster do the same thing with Canada at his back? Obviously we need a business, not a political engineer at the head of our Trade and Commerce Department.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., July 5, 1915.—The demand for machine tools of all kinds, particularly engine and turret lathes, continues very brisk with deliveries promised three months from date of placing order. In this line there is a wider and more promising outlook than appears at first sight. For example, with the pressure to which machine tools are being subjected, the night and day shifts, coupled with the added incentive of piece-work prices, the life of equipment at present in use will not be of long duration. In other words, even in plants now fully equipped, there will be a steady and consistent demand for new machine parts and also complete machines.

Just at present, according to some machine tool users, there is great opportunity for the manufacture of lathes, shapers, presses and milling machines. On the other hand it is claimed that after the finish of the war there will be a glut of machine tools on the market. This latter argument is, however, refuted by the fact that even for the duration of the war most shops will have to renew their equipment units entirely.

There is not much difference in prices of electrolytic copper between New York and Montreal, the price in the former place being one cent a pound cheaper than locally. August deliveries are offered at 19¾c cash New York. The outlook is that the price of copper will con-

tinue to soar owing to increased consumption on account of war demands, it being highly problematical as to whether production will keep pace with the consumption. The opinion of leading military authorities seems to be in agreement that the war has yet two years to run. All this is more or less guesswork, however; at the same time there is considerable capital invested on the strength of such a long drawn out struggle. Finished steel prices have been extremely well maintained.

Antimony still continues at 40 cents a pound., which is a considerable increase from 7 cents, the ruling price in the ante bellum days. The demand in this country for antimony is large and persistent.

The price of tin has not shown any great variation in spite of the fact that consumption is fairly strong.

Aluminum is quoted at 40 cents, but buyers seem reluctant to pay this price. Bids of 38c have been made, but nothing seems to be available at that figure.

While metal prices generally have been rising steadily, the price of second-hand lead is quoted at 4½c, with more frequent offers and prompt deliveries. In fact, most all waste metals this week show a considerably easier feeling, with red brass and red brass turnings down one cent.

The recent flurry in spelter prices which, it is alleged in some quarters, were deliberately marked down to facilitate the purchase of low-priced concentrates by the very people who will be interested later in getting as high a price as possible for the refined product, did not have any lasting effect on the market. There was a rumor that manipulative tactics were being resorted to which caused the prices to remain firm. There is every evidence of a fresh buying movement being close at hand.

While no large contracts are yet being booked, there are many inquiries in the market. The way things are going, the "stand-patter" is about on an equal footing with the more venturesome. Just to demonstrate what the activity is in this metal, the New Jersey Zinc Co. has declared an extra cash dividend of 30 per cent. It is also rumored that their capital stock will be increased three and one-half times.

Toronto, Ont., July 6, 1915.—The development of foreign business and the manufacture of war equipment, including munitions, are the chief matters of interest in commercial circles. With ordinary business dull and little prospect of any material improvement for some time to come, there is every incentive for our manufacturers to look to other fields rather than at home. As regards this new feature, prospects are improving and it is anticipated that not only will further war orders be placed with Canadian manufacturers, but also orders for equipment not necessarily for the allied armies, but as a result of the war. The contracts for locomotives and cars already placed will no doubt be followed by others. Shells for the Russian Government are being made here and it is expected that manufacture of shells for the French Government will be commenced shortly. It is expected that the visit of David A. Thomas, the representative of the British Government, will result in large orders for war material being placed in Canada.

> **COMING CONVENTIONS.**
>
> **American Foundrymen's Association, Atlantic City, N.J.—Sept. 27-Oct. 1.**
>
> **Foundry and Machine Exhibition Co., Atlantic City, N.J.—Sept. 25-Oct. 2.**

Conrad F. Just, special Trade Commissioner for Canada to Russia, has sent an interesting report from Petrograd to the Department of Trade and Commerce. Mr. Conrad advises Canadian traders to organize on the basis of a close study of Russian requirements and to keep in touch with the consumer by means of local agents. He states that it is desirable to have assembling shops in Russia, particularly for machinery, thus effecting a saving on customs duties and permitting tendering on Government works.

Steel Market.

The mills have made an advance of $1 per ton on steel bars, plates and shapes, and quotations are now $1.25 f.o.b. Pittsburgh, with steel hoops at $1.30 at the same point. Canadian mills are quoting $2.15 f.o.b. Toronto and Montreal. Prices are very firm at the advance and may be raised again. The active demand for steel bars for shells continues with an increase in tonnage. Specifications for French shells have been issued and good business is expected from this source, as well as from Russia. Merchant business continues quiet, and statistics show a sharp decline in the building trade.

> **CANADIAN GOVERNMENT PURCHASING COMMISSION.**
>
> **The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George Gault, Winnipeg; Henry Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.**

Since the last advance in galvanized sheets, the spelter market has been easier but is recovering. Prices of sheets weakened, but are firm again and another advance is probable, as the spelter market is stronger. The continued abnormal price of spelter is affecting the output of galvanized sheets considerably. Some makers have withdrawn from the market entirely and others are asking higher prices for their product. Galvanized pipe is firm at the higher prices announced last week and makers are seriously affected by the spelter situation. Cold rolled strip steel has advanced $2 per ton. Prices on cold drawn steel shafting have been withdrawn pending an advance which it is expected will be about $2 per ton.

In the United States the steel market continues active and prices on all products are firm. Further large orders for ammunition are pending and there is a big demand for high-grade bars for shells. There is a better demand for steel plates owing to domestic consumption, and also on account of big business being done in the ship-building industry.

Pig Iron.

The market continues dull and the situation shows no improvement. Prices are unchanged.

Scrap Metals.

Quotations on copper and brass scrap are holding very firm on good demand. Scrap zinc has recovered and has advanced, being now quoted at 16c per pound. Lead prices are firm but unchanged. The market for iron and steel scrap is quiet and prices unchanged.

Machine Tools.

The market is distinctly quieter as regards new inquiries, but dealers are busy filling orders already placed. Deliveries are no better, the ingenuity of makers and dealers being taxed to satisfy customers so that they may begin operations with as little delay as possible. Second-hand machines tooled up for making shells are being requisitioned to make up for the deficiency in new equipment. There is a temporary lull as regards new shell contracts and also shipment of shell cases, but when plants of sufficient capacity for turning out fixed ammunition have been equipped, there will no doubt be increased activity in the shell industry and interesting developments may be expected.

Supplies.

The supply business is very good and prices are holding firm. The demand is principally from the shell plants, although ordinary business is showing some improvement. There are no price changes to note this week.

Metals.

There are few price changes to note in the metal market this week, for with the single exception of aluminum, which has advanced, all markets are steady. There is a big demand for this metal and supplies are scarce. The tin market has a weaker tendency, but the price is unchanged. Copper likewise is unchanged and the market stagnant. Spelter is firm at the advance announced last week and the situation shows no improvement. The lead market is weak but quotations generally are being maintained. The antimony market is dull, but the position of this metal is good. The New York metal exchange was closed on Monday.

Tin.—The market is quiet with a weaker tendency in London. The consumption of tin is on the increase and higher prices may result. Tin is quoted locally at 46c per pound.

Copper.—The situation is unchanged. The London market is lower due to the increase in stocks of copper in England and France, while the New York market is stagnant, and prices unchanged. The consumption of copper continues very heavy and will increase owing to the enormous demand for ammunition. The copper position is therefore a strong one and higher prices are looked for. Local quotations for copper are unchanged at 21½c per pound.

Spelter.—The situation continues serious and supplies are very scarce. Most of the demand is from the brass mills, but there is also considerable from galvanizers. The market is firm and unchanged with prices nominal at 28c per pound.

Lead.—The market is lower in London but firm in New York. Producers are well sold ahead, and the market has a steadier tendency. Locally, prices are holding firm and are unchanged at 7½c per pound.

Antimony.—The market is dull, but is holding up well. With the increase in the demand for ammunition, there will be a greater consumption of antimony. Quotations are unchanged and nominal at 40c per pound.

Aluminum.—The market is strong and has advanced again. There is a heavy demand for this metal, and supplies are very scarce. Aluminum has advanced 5c and is quoted at 40c per pound.

The Hudson's Bay Co. has been appointed purchasing agents in Canada for the French Government.

High Speed Steel Price.—Tungsten is one of the chief ingredients of high speed steels, its average being about 18 per cent. in every pound. As it has quite tripled in price within a short period, and is at that hardly obtainable, it was only reasonable to expect that the price of high speed steel would show a considerable and, of course, proportional increase.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Halifax, N.S.—The Starr Mfg. Co., have equipped their plant to make shells.

Truro, N.S.—The Truro Engineering Works, Ltd., have received an order for shells, and will proceed to install the necessary equipment.

Renfrew, Ont.—It is announced that the Smith mill owned by M. J. O'Brien will be converted into a machine shop and equipped with machinery for making shells.

Orillia, Ont.—The E. Long Mfg. Co. will undertake the manufacture of shells for the British Government. The initial order of 15,000 high explosive shells has been received.

Kingston, Ont.—A special committee of the city council have recommended that a boiler be purchased from the Jenckes Machine Co. for the proposed incinerator.

Welland, Ont—William G. Edwards of the International Specialty Co., is planning to equip the plant with machinery to manufacture shells for the French Government.

Calgary, Alta—The local branch of the Ford Motor Co. has secured an option on the property at the north-west corner of Eighth street west and Eleventh avenue, where it is planned to erect an assembling factory.

New Glasgow, N.S.—McNeil Bros., who are manufacturing shells, have leased the rink at Stellarton, which they will convert into a machine shop, in which shells and their parts will be made. New machinery costing $75,000 will be installed as soon as possible.

Municipal

Calgary, Alta.—The city is planning to build a big reservoir and a water filter.

Millardville, Ont.—The council are considering installing a waterworks system.

Collingwood, Ont.—The Town Council contemplate making improvements to the waterworks system.

The Pas Man.—A by-law will be submitted to raise $80,000 for the construction of a system of waterworks and sewerage.

Port Hope, Ont.—The by-law has passed authorizing an expenditure of $35,000 on waterworks improvements.

Whitby, Ont.—The completion of the sewer system is contemplated by the Town Council. A by-law will be submitted.

Kamsack, Sask.—The town council propose to construct an addition to the waterworks system, estimated to cost $35,000.

Lambeth, Ont.—The council propose to install a waterworks system, at an estimated cost of $15,000. Engineers J. A. Bell & Son.

Vancouver, B.C.—Seven by-laws for the purpose of raising three-quarters of a million dollars were defeated by the electors on June 28.

Matheson, Ont.—A by-law will be voted on by the ratepayers on July 16, to raise $20,000 to pay for the construction of a waterworks system.

Vernon, B.C.—The city council propose to install an auxiliary pumping station at B. X. Creek at a cost of $3,000. Ald. Clement is chairman of the Water Committee.

Hamilton, Ont.—By-laws have been passed by the City Council authorizing the issuing of debentures for $250,000 for the city's and owner's share of the McKittrick bridge and waterworks extension.

Mimico, Ont.—With the closing of the deal between the Villages of New Toronto and Mimico, for a supply of water to the latter municipality, the Mimico Council immediately intend to proceed with the work of laying the mains.

Toronto, Ont.—W. A. McLean, Provincial Highways Engineer, reports that the Toronto-Oshawa highway constructed of macadam would cost $239,000, and if made of concrete $625,000. The cost would be divided among the various municipalities interested.

The Pas, Man.—The town has given notice in the current issue of the Manitoba Gazette of its purpose to establish a system of electric light and power in its municipality at a cost not to exceed $50,000. The money will be raised by sale of debentures. The by-law will be submitted to the electors on July 15.

London, Ont.—The city council are considering awarding the following contracts for machinery for the Springbank pumping station:—Motors to Canadian Westinghouse Co., Hamilton, at $6,400; waterwheels to Hamilton Co., Peterboro, at $7,595, and pumps to the John MacDougall Caledonian Iron Works, Montreal, at $4,710.

ALLIES PURCHASING AGENTS.

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:—

International Purchasing Commission, India House, Kingsway, London, Eng.

British.—Col. A. G. Barton and F. W. Stobart, Ritz Carlton Hotel, Montreal.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendance Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminister, London.

Russian.—Messrs. S. Ruperti and Aieksieff, care Military Attache, Russian Embassy, Washington, D.C.

General Industrial

London, Ont.—The proposed breakwater at West London will probably be constructed of concrete.

Renfrew, Ont.—It is announced that the Jamieson Brick & Tile Co. will establish another plant here.

Owen Sound, Ont.—The Town Council has decided not to proceed with the scheme for building an elevator here.

Redcliffe, Alta.—A cyclone on June 25 did considerable damage to the planing mill here and several other factories.

Eburne Station, B.C.—It is announced that the B.C. Grinnell Glove Co., of Vancouver, will locate a branch of their business here.

Sorel, Que.—The factory of the Sorel Bottling Co., recently destroyed by fire with a loss of $7,000, will be rebuilt. New machinery will be required.

The Relation Between Production and Cost Compared*

By H. L. Gantt

It has been common practice to make the product of a factory running at part capacity to bear the whole expense. This is recognized by many as illogical, although no rational theory as to what proportion of expense such product should bear has been advanced.

MANUFACTURERS in general recognize the vital importance of a knowledge of the cost of their product, yet but few of them have a cost system on which they are willing to rely under all conditions.

While it is possible to get quite accurately the amount of material and labor used directly in the production of an article, and several systems have been devised which accomplish this result, there does not yet seem to have been devised any system of distributing that portion of the expense known variously as indirect expense. burden or overhead, in such a manner as to make us have any real confidence that it has been done properly.

Indirect Expense Distribution.

There are in common use several methods of distributing this expense. One is to distribute the total indirect expense, including interest, taxes, insurance, etc., according to the direct labor. Another is to distribute a portion of this expense according to direct labor, and a portion according to machine hours. Other methods distribute a certain amount of this expense on the material used, etc. Most of these methods contemplate the distribution of all of the indirect expense of the manufacturing plant, however much it may be, on the output produced, no matter how small it is.

If the factory is running at its full or normal capacity, this item of indirect expense per unit of product is usually small. If the factory is running at only a fraction of its capacity, say one-half, and turning out only one-half of its normal product, there is but little change in the total amount of this indirect expense, all of which must now be distributed over half as much product as previously, each unit of product thereby being obliged to bear approximately twice as much expense as previously.

When times are good, and there is plenty of business, this method of accounting indicates that our costs are low; but when times become bad and business is slack, it indicates high costs due to the increased proportion of burden each unit has to bear. During good times, when there is a demand for all the product we can make, it is usually sold at a high price and the element of cost is not such an important factor. When business is dull, however, we cannot get such a high price for our product, and the question of how low a price we can afford to sell the product at is of vital importance. Our cost systems, as generally operated at present, show under such conditions that our costs are high, and if business is very bad, they usually show us a cost far greater than the amount we can get for the goods. In other words, our present systems of cost accounting go to pieces when they are most needed. This being the case, many of us have felt for a long time that there was something radically wrong with the present theories on the subject.

As an illustration, I may cite a case which recently came to my attention. A man found that his cost on a certain article was 30 cents. When he found that he could buy it for 26 cents, he gave orders to stop manufacturing and to buy it, saying he did not understand how his competitor could sell at that price. He seemed to realize that there was a flaw somewhere, but he could not locate it. I then asked him what his expense consisted of. His reply was labor 10 cents, material 8 cents, and overhead 12 cents. My next question was:—Are you running your factory at full capacity? and got the reply that he was running it at less than half its capacity, possibly at one-third. The next question was: What would be the overhead on this article if your factory were running full? The reply was that it would be about 5 cents; hence the cost would be only 23 cents. The possibility that his competitor was running his factory full suggested itself at once as an explanation.

The next question that suggested itself was how the 12 cents overhead, which was charged to this article, would be paid if the article was bought. The obvious answer was that it would have to be distributed over the product still being made, and would thereby increase its cost. In such a case it would probably be found that some other article was costing more than it could be bought for; and, if the same policy were pursued, the second article should be bought, which would cause the remaining product to bear a still higher expense rate. If this policy were carried to its logical conclusion, the manufacturer would be buying everything before long, and be obliged to give up manufacturing entirely. The illustration which I have cited is not an isolated case, but is representative of the problems before a large class of manufacturers, who believe that all of the expense, however large, must be carried by the output produced, however small.

This theory of expense distribution is quite widespread, and clearly indicates a policy, which in dull times would, if followed logically, put many of our manufacturers out of business. In 1897 the plant of which I was superintendent was put out of business by just this kind of logic. It never started up again.

Fortunately for the country, our people as a whole will finally discard theories which conflict with common sense; and, when their cost figures indicate an absurd conclusion, most of them will repudiate the figures. A cost system, however, which fails us when we need it most, is of but little value and it is imperative for us to devise a theory of costs that will not fail us.

Systems Devised by Accountants.

Most of the cost systems in use, and the theories on which they are based, have been devised by accountants for the benefit of financiers, whose aim has been to criticize the factory and to make it responsible for all the shortcomings of the business. In this they have succeeded admirably, largely because the methods used are not so devised as to enable the superintendent to present his side of the case.

Our theory of cost keeping is that one of its prime functions is to enable the superintendent to know whether or not he is doing the work he is responsible for as economically as possible, when function is ignored in the majority of the cost systems now in general use. Many accountants, who make an attempt to show it, are so long in getting their figures in shape that they are practically worthless for the purpose intended, the possibility of using them having passed. In order to get a correct view of the subject we must look at the matter from a different and broader standpoint. The following illustration seems to put the subject in its true light:—

Let us suppose that a manufacturer owns three identical plants, of an economical operating size, manufacturing the same article, — one located in Albany, one in Buffalo, and one in Chicago,—and that they are all running at their normal capacity and managed equally well. The amount of indirect expense per unit of

*From a paper read at the Spring Meeting, American Society of Mechanical Engineers.

product would be substantially the same in each of these factories, as would be the total cost. Now suppose that business suddenly falls off to one-third of its previous amount and that the manufacturer shuts down the plants in Albany and Buffalo, and continues to run the one in Chicago exactly as it has been run before. The product from the Chicago plant would have the same cost that it previously had, but the expense of carrying two idle factories might be so great as to take all the profits out of the business; in other words, the profit made from the Chicago plant might be offset entirely by the loss made by the Albany and Buffalo plants. If these plants, instead of being in different cities, were located in the same city, a similar condition might also exist in which the expense of the two idle plants would be such a drain on the business that they would offset the profit made in the going plant.

Size of Plant.

Instead of considering these three factories to be in different parts of one city, they might be considered as being within the same yard, which would not change the conditions. Finally, we might consider that the walls between these factories were taken down and that the three factories were turned into one plant, the output of which had been reduced to one-third of its normal volume. Arguing as before it would be proper to charge to this product only one-third of the indirect expense charged when the factory was running full.

If the above argument is correct we may state the following general principle: THE INDIRECT EXPENSE CHARGEABLE TO THE OUTPUT OF A FACTORY BEARS THE SAME RATIO TO THE INDIRECT EXPENSE NECESSARY TO RUN THE FACTORY AT NORMAL CAPACITY, AS THE OUTPUT IN QUESTION BEARS TO THE NORMAL OUTPUT OF THE FACTORY.

This theory of expense distribution, which was forced upon us by the abrupt change in conditions brought on by the war, explains many things which were inexplicable under the older theory, and gives the manufacturer uniform costs as long as the methods of manufacture do not change. Under this method of distributing expense there will be a certain amount of undistributed expense remaining whenever the factory runs below its normal capacity. A careful consideration of this item will show that it is not chargeable to the product made, but is a business expense incurred on account of our maintaining a certain portion of the factory idle, and chargeable to profit and loss. Many manufacturers have made money in a small plant, then built a large plant and lost money for years afterwards, without quite understanding how it happened. This method of figuring gives a clear explanation of that fact and warns us to do everything possible to increase the efficiency of the plant we have, rather than to increase its size.

This theory seems to give a satisfactory answer to all the questions of cost that I have been able to apply it to, and during the past few months I have laid it before a great many capable business men and accountants. Some admitted that this viewpoint would produce a very radical change in their business policy, and are already preparing to carry out the new policy. It explains clearly why some of our large combinations of manufacturing plants have not been as successful as was anticipated, and why the small, but newer plant, is able to compete successfully and make money, while the combinations are only just holding their own.

The idea so prevalent a few years ago, that in the industrial world money is the most powerful factor, and that if we only had enough money, nothing else would matter very much, is beginning to lose its force, for it is becoming clear that the size of a business is not so important as the policy by which it directed. If we base our policy on the idea that the cost of an article can only legitimately include the expense necessarily incurred either directly or indirectly in producing it, we shall find that our costs are much lower than we thought, and that we can do many things which under the old method of figuring appeared suicidal.

Common Acceptation of Cost.

The view of costs so largely held, namely, that the product of a factory, however small, must bear the total expense, however large, is responsible for much of the confusion about costs and hence leads to unsound business policies. If we accept the view that the article produced shall bear only that portion of the indirect expense needed to produce it, our costs will not only become lower, but relatively far more constant, for the most variable factor in the cost of an article under the usual system of accounting has been the "overhead," which has varied almost inversely as the amount of the product. This item becomes substantially constant if the "overhead" is figured on the normal capacity of the plant. Of course a method of accounting does not diminish the expense, but it may show us where the expense properly belongs, and give us a more correct understanding of our business.

In our illustration of the three factories, the cost in the Chicago factory remained constant, but the expense of supporting the Buffalo and Albany factories in idleness was a charge against the business, and properly chargeable to profit and loss. If we had loaded this expense on the product of the Chicago factory, the cost of the product would probably have been so great as to have prevented our selling it, and the total loss would have been greater still.

When the factories are distinctly separate, few people make such a mistake, but where a single factory is three times as large as is needed for the output, the error is frequently made, with results that are just as misleading. As a matter of fact it seems that the attempt to make a product bear the expense of plant not needed for its production is one of the most serious defects in our industrial system to-day, and farther reaching than the differences between employers and employees.

The problem that faces us is then first to find just what plant, or part of a plant, is needed to produce a given output, and to determine the "overhead" expense on operating that plant or portion of a plant. This is primarily the work of the manufacturer, or engineer, and only secondarily that of the accountant, who must, as far as costs are concerned, be the servant of the superintendent. In the past, in almost all cost systems the amount of "overhead" to be charged to the product, when it did not include all the "overhead," was more or less a matter of judgment. According to the theory now presented, it is not a matter of judgment, but can be determined with an accuracy depending upon the knowledge the manufacturer has of the business. Following this line of thought it should be possible for a manufacturer to calculate just what plant and equipment he ought to have, and what the staff of officers and workmen should be to turn out a given profit. If this can be correctly done, the exact cost of a product can be predicted. Such a problem cannot be solved by a cost accountant of the usual type, but is primarily a problem for an engineer, whose knowledge of materials and processes is essential for its solution.

Functions of a Cost System.

Having made an attempt to solve a problem of this type, one of the most important functions we need a cost system to perform, is to keep the superintendent continually advised as to how nearly he is realizing the ideal set, and to point out where the shortcomings are. Many of us are accustomed to this viewpoint when we are treating individual operations singly, but few have as yet made an attempt to consider that this idea might be applied to a plant as a whole, except when the processes of manufacture are simple and the products few in number. When, howver, the pro-

cesses become numerous or complicated, the necessity for such a check becomes more urgent, and the cost keeper who performs this function becomes an integral part of the manufacturing system, and acts for the superintendent, as an inspector, who keeps him advised at all times of the quality of his own work.

This conception of the duties of a cost keeper does not at all interfere with his supplying the financier with the information he needs, but insures that information shall be correct, for the cost keeper is continually making a comparison for the benefit of the superintendent, of what has been done with what should have been done. Costs are valuable only as comparisons, and comparisons are of little value unless we have a standard, which it is the function of the engineer to set.

Lack of reliable cost methods has, in the past, been responsible for much of the uncertainty so prevalent in our industrial policies; but with a definite and reliable cost method, which enables us to differentiate between what is lost in manufacturing and what is lost in business, it will usually become easy to define clearly the proper business policy.

TRADE OPPORTUNITIES IN THE ARGENTINE REPUBLIC.

THE Argentine Republic representative of the Department of Trade and Commerce, Ottawa, deals in a recent report with the following trade opportunities which may be made more or less available:

Tools.

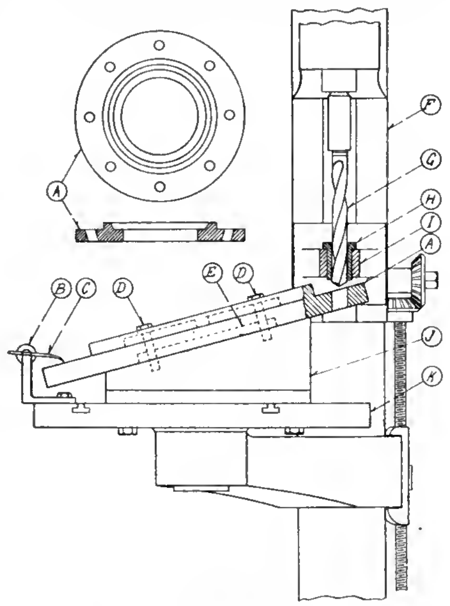
Tools, such as axes, carpenters' tools, taps and dies, spanners, etc., have been imported from the United Kingdom, United States, Germany and France, and in axes and certain classes of carpenters' tools some well-known United States manufacturers are doing a considerable export business. In hand-saws, a very well-known United States make has a strong position, but there is reason to believe that a Canadian-made article of equal price and quality would eventually be able to compete against it. Carpenters' hammers have heretofore been purchased to a very large extent in the northern part of France, and in Alsace. Although this area is included in the war zone, the stocks in hand prevented any shortage being felt, but as they are doubtless becoming depleted, this state of affairs will probably change.

Bolts, Nuts, Screws, Etc.

In Carriage bolts, a Buffalo company practically controls the market, and United States screw companies have a large control of the market in wood screws; in fact, one of these companies has been successful in overcoming the competition of a well-known Birmingham firm, as well as a manufacturer in France. One firm sends the screws wrapped up in small paper packets, tied with string, and another puts them up in neat folding card-board boxes. One large firm stated that three hundred different sizes of screws had to be kept in stock, and for that reason, packing becomes very important. Flat-headed screws are the ones more generally used.

Valves.

English manufacturers have in the past controlled the trade in valves, but owing to the dislocation of business, it will probably be difficult for them to hold it. Canadian manufacturers of valves have an excellent opportunity to extend their sales, as this class of goods is always more or less in demand. A local firm stated that they had been endeavoring to form connections in Canada, but the manufacturer, whom they approached, refused to extend any terms of credit to this market. This seems unfortunate, especially in this instance, as the firm's clients are houses of good standing.



JIG FOR DRILLING ANGULAR HOLES.

Split Wood Pulleys.

Split wood pulleys, although imported into Argentina, are also manufactured in the country.

Metal Goods.

There has been a strong demand for metal lathing, but owing to the present dislocation of the building trade, this has almost entirely ceased, except for those buildings which are being completed. This demand, however, will probably appear again when times become more prosperous. Canadian manufacturers therefore should not wait until prosperity sets in, but should now form their connections so that they may be ready to take advantage of the improvement in business whenever this may occur. The Canadian product seems to be able to compete with that of any other country.

The same cannot be said of metal ceilings and stamped metal work manufactured in the United States, which, owing perhaps to the greater output, seems to be able to underbid Canadian prices.

Metal tiles, which are used in Canada do not meet with acceptance here, as they require wooden sheathing beneath them, without which they would be penetrated by hail. The necessity for the sheathing constantly renders the price prohibitive.

There should be some sale for metal culverts, although at the present time there is not much demand for them.

DRILLING ANGULAR HOLES.

By R. Garth.

THE illustration shows a jig for drilling the holes in the piece A at an angle with the base. The piece J is secured to the drill table K; the upper surface—which is turned to the required angle, having a boss to fit the bore of A, which is secured to the piece J in the desired position.

Secured to the drill press upright F is the piece I, which carries the hardened drill bush H, through which the drill G is fed to the work. The piece I is adjustable in a vertical position and always maintains the drill bush H in a central position relative to the drill spindle. By releasing the clamping bolts D, the work is shifted to the next desired location, which is found by the scriber C.

By using a variety of drill bushes H, the piece I can be used for quite a number of different jobs.

The conditions under which aeroplane guns operate are new to the scientist, and the ordinary trajectory formulæ do not wholly apply, principally because of the altitude from which the gun is fired. Guns fired from the ground attain a long range by means of high muzzle elevation, but the aeroplane gun is fired from a great height and has consequently a much greater range, there being stored in the shot fired from it the potential energy due to the height. Thus, if a 3-in. shot were fired from a height of 10,000 ft., there would be potential energy stored in it of 60,000 foot-pounds and, if fired with the gun barrel horizontal, the range would be considerably over 12,000 yards. The same gun, fired from the surface of the earth would have an extreme range of 2,000 yards only.—Ex.

CONCERNING DROP FORGINGS FOR AUTOMOBILES.*

By Arthur Stubbs.

THE number of parts or pieces required has an important bearing on the question as to whether these shall be drop forgings or otherwise. If the number of parts required is very small, say less than 100, it may be better to use a casting or a forging, as the cost of a pattern is less than that of a pair of dies, and reduced first cost may outweigh the other advantages of the drop forging. If, however, a considerable number of similar parts are required, the exact number depending largely on the simplicity or otherwise of the design, and also on the dies, drop forgings should be used, as they will give greater consistency in the metal than a casting, so that machining is easier, while the part can be produced with greater accuracy and more closely to size than either a casting or forging. The machining cost will be less, as there will be less metal to remove, except in the case of such a part as a hub, where a casting could be cored out. A drop forging will also be stronger than a casting of the same weight, or lighter for the same strength.

There is, of course, nothing to choose under this head between drop forgings and hand forgings. It is, perhaps, hardly necessary to point out that the process of cutting from the solid can only be applied to a somewhat limited number of parts of the automobile, and they must be of simple and regular form, but if the cost of the dies is taken as the equivalent of that of the special tools necessary for a particular job, a part may probably be machined from the solid more cheaply than a drop forging can be finished. The forging, however, will be stronger, as the operation of forging makes the metal more homogeneous and improves the structure, while in many pieces the grain of the metal will run in a direction which gives better resistance to the stresses.

Material of Dies.

The dies, which may be taken to correspond to the mould for a casting, are made in a variety of materials, depending upon the class of forging and the number required. Cast iron is now seldom used, except in the case of fairly large and plain parts made in wrought iron or mild steel (soft). Common Bessemer steel blocks are used when the quantity required is small and the article fairly simple and large, so that the material for the forging is not hard to work and the dies need not be hardened. The material most generally used is a high-grade Siemens acid steel, made upon a Swedish base, thus containing some "body," so essential to toughness in dies. A general analysis of such a steel is as follows: Carbon, 0.65 per cent.; manganese, 0.60 per cent.; silicon, 0.045 per cent.; sulphur, .02 per cent.; phosphorus, 0.025 per cent.

Crucible cast steel is used when the article is small and the quantity great, and also when the material for the forging is hard to work, such as a high-carbon or alloy steel. Nickel steels have also been used, generally owing to their greater toughness, but it is only in exceptional cases that the cost of this material is justifiable. It is a good axiom to use the best material possible compatible with the cost, as the risk of breakage due to using a poor quality of steel is great, and the few dollars extra cost per 100 lbs. is unimportant compared with the cost of replacing a broken die.

Life of Dies.

The number of forgings which a pair of dies will make depends upon the quality of the steel used for the blocks, the quality of the steel used for the forgings (that is, whether it is ordinary mild steel, high-carbon steel or an alloy steel), and the design of the article, whether it is simple or one requiring very deep or sharp angular impressions. The life of a die is also largely governed by the amount of metal required to be removed for a single re-cut, though it is very seldom in practice that a pair of dies are really worn out in automobile work, as they can usually outlast the design.

The allowance for fin—that is, the thickness of metal between the top and bottom dies, varies from about 1/8 in. to 1/4 in., but, as will readily be appreciated, this depends upon the weight and design of the forging. In many cases the dies must be guttered, so as to allow the waste metal to flow out more easily. This is particularly necessary where the forging has very deep bosses, as dies are very often broken, through the material choking the die owing to the smallness of the outlet or gutter.

In order that the guttering of dies should be fully understood, it may be well to point out that reference is made to something more than the outlet at the end of the die which allows the material to flow out with the tag (the tag being described as the porter-bar, which is welded on to the material being used for the forging). The face of the bottom die is cut away in corrugations so that instead of the die presenting a perfectly flat surface, the actual finishing impression stands up slightly above the face owing to the other part of the die being corrugated. This is very important in the case of forgings which are very liable to choke a die owing to a very deep boss and so on. It also enables the material to flow out evenly in all directions, and, in consequence, the forgings contract more uniformly during cooling.

Production Tolerance.

A drop forging can be produced to a tolerance of 1-32 in. as an ordinary commercial limit for small work, though it is quite possible by careful forging and supplemental re-striking, and provided that the forging is fairly small, to produce work within a few thousandths of an inch of dead size. The degree of accuracy possible in drop forging is, however, very seldom realized, and for work within very fine limits it is absolutely necessary to have multiple dies, that is, one or more pairs of dies for roughing out, and one or more pairs of dies for the finishing operations. It would very often pay to have forgings re-struck, preferably in a pair of finishing dies, especially when the part can be jigged for machining, as the difference in cost between jigging a piece and setting it up separately is very considerable.

Multiple Dies.

In many cases multiple dies are desirable but prohibitive on account of their cost, their use being limited owing to the small number of pieces of any given pattern usually required. A connecting rod made in alloy steel, especially when the rod is to be within a fine weight-limit and carefully balanced, may be quoted as an instance where multiple dies would be desirable. Multiple dies are also necessary if it is desired to eliminate the stresses set up in forging, due to large and deep bosses being adjacent to very thin and long webs. The necessity for eliminating sharp corners and angles, and avoiding the design of parts which have deep and very thin sections is urged. It is also very desirable that the designer should work with the drop forger in this matter.

*From a paper read before the Institution of Automobile Engineers.

After the dies have been cut and tested for correctness with the lead impression, they are then carefully hardened if they are small, but large dies are not usually hardened owing to the risk of breakage. The necessity for slow and uniform heating of dies for hardening is a very important factor, and quite as much care has to be taken to avoid distortion as in hardening a gear blank. The defects due to rapid heating and sudden quenching are well known, but it may be desirable to point out that this very often results in a broken or badly distorted die, which gives rise to the complaint that the forging is not to shape.

Keeping Dies Cool and Clean.

It is very necessary that, during the process of forging, the face of the die should be kept cold, and this is accomplished by directing a blast of air from a 1-in. to 1½-in. diameter pipe on to the face. It is also necessary to keep the dies clean, which is usually accomplished by using a wire brush. To prevent the work from sticking in the die, oil is used, which is thrown into the top die, as the tup rises, by the use of a swab or stick. After the piece has been finished in the die, the fin has to be removed in a pair of trimming dies, which consist of a bed cut out to the finished shape of the forging, and this forms the bottom die, while a punch, formed to the profile of the forging, forms the top die and presses the forging through the bed, thus leaving the fin around the punch. It is scarcely necessary to point out that the fin is removed by a suitably-geared press.

Steel for Automobiles.

In considering the various classes of steel used in the construction of motor cars, it is curious to notice that in many cases where an automobile manufacturer has found a steel which gives him the minimum of trouble he will specify it for every conceivable part. It is common to find a low-carbon, case-hardening steel actually used for steering levers, or a high-nickel-chrome steel for a connecting rod, while a crank-shaft is made of ordinary 0.30 per cent. carbon steel.

As to who should be actually responsible for the choice of the steel to be used in any particular part of a car, there are three alternatives. The automobile maker may (1)—specify both the maker and the quality of the steel; (2)—tell the steelmaker what he wants and allow him to recommend the quality his experience shows to be the most suitable; or (3)—specify his tests and the purpose for which the part is required, and then ask the drop forger to supply a part to meet that test and hold him responsible.

In the first case the automobile manufacturer assumes responsibility as to the final tests, yet in the event of trouble he blames the drop forger or the steelmaker, or probably both. The steelmaker will claim that the drop forger has spoiled the steel by incorrect treatment, and the drop forger will reply that the steel was unsuitable. If the steelmaker accepts the test specified by the automobile manufacturer and recommends a steel for a particular part, he should be held responsible for the final test, provided the instructions he furnishes have been carried out. So far as bar material is concerned, that is probably quite satisfactory, but, in the case of material to be worked up by the drop forger, it leaves a loophole for the steelmaker to evade responsibility by saying that the drop forger has ruined the steel. This may be true, but the ruin may be caused either by careless treatment in not carrying out the steelmaker's instructions, incorrect treatment due to his ignorance of the properties of the steel, for which the steelmaker is largely responsible, or working a steel which was totally unsuitable for that particular part, and for which the steelmaker is responsible. Abundant evidence is available to prove that the steelmaker is not the best qualified to recommend, in all cases, a steel for any particular part.

If the drop forger accepts the test specified by the automobile manufacturer as being reasonable, he can be held responsible for the finished part, because he has a free hand in the choice of the material he buys and of the maker from whom he buys it; he will confine himself to the use of those steels which his experience tells him are most reliable and with the properties of which he is fully acquainted, and this will tend to a more uniform output.

A PISTON RING FIXTURE.

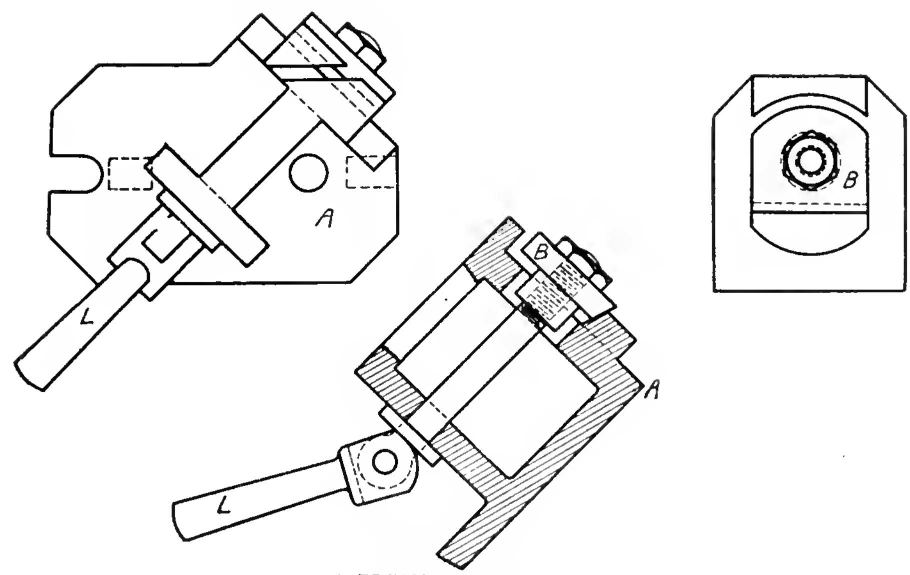
By D. S. Mann.

IN the drawing is shown a fixture for holding piston rings of the smaller sizes while parting same, this being designed particularly for use on the hand-milling machine, although, of course, it is adaptable for the regular machine. The work, however, can be done much more advantageously and cheaply on a hand-fed machine.

The fixture comprises the one main casting A, this being bolted to the machine table, and being provided with lugs for locating in the table slots. The particular rings in this case were split at an angle of 45°, so that the vertical face of the fixture is placed at this angle. The end view and section shows the projecting lug at the top, this being turned to the proper radius for the ring. The latter is held between this lug and the clamping piece B. The clamping piece is cut at a bevel on the bottom, and rests on a corresponding bevel on the main casting; this is operated by means of the cam lever L through the eye bolt.

It will be noticed that the two vertical parts of the main casting are joined by a rib at the top for strength. A heavy spring, not shown in the drawing, is placed around the eye bolt so as to push out the clamping piece B when the cam is released. This cam works on a hardened steel washer. When the cam lever is depressed, the piece B is drawn in, rising on the bevel and clamping the ring which has been placed on the top of same and beneath the projecting lug at the top.

The eye bolt is threaded into the piece B, and is provided with a lock nut, so that adjustments can be quickly made. The cut made by the milling cutter is, of course, carried entirely through the upper part of the frame and lug, and this serves to centre up the cutter.



A PISTON RING FIXTURE.

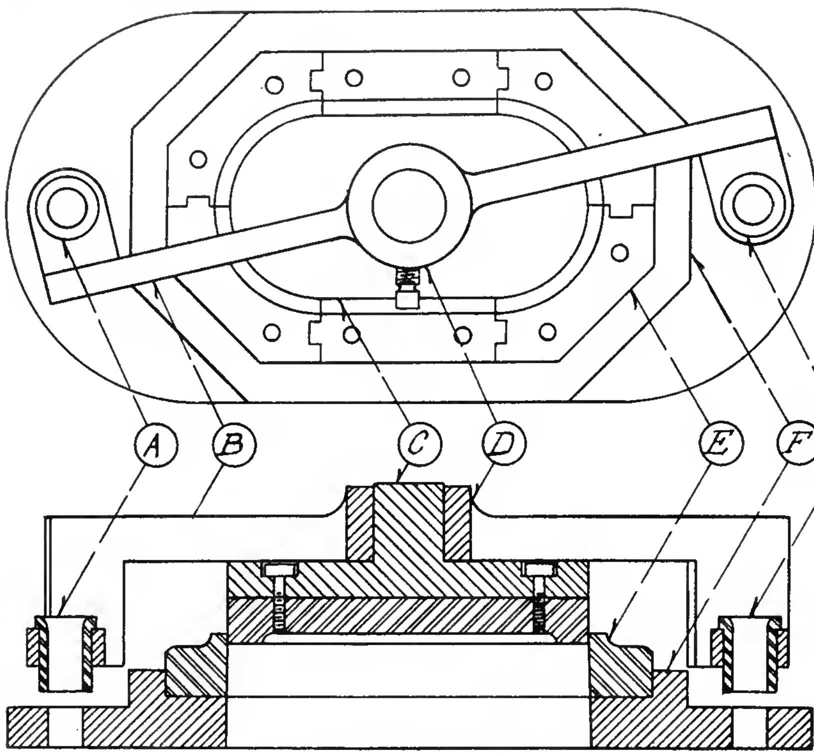
PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

DRILL JIG FOR DIE BED.

By G. Hamilton.

THE accompanying sketch shows a useful jig for drilling the clamping holes in dies for the punch press, it being sometimes very unhandy to locate these holes in the proper position, especially when the contour of the die is of an irregular shape.



DRILL JIG FOR DIE BED.

The punch C and the die E, being fitted, the jig B is placed upon the shank of the punch holder C, and secured by the set screw shown in the position required. The drilling is performed through the hardened bushes A and G in the usual manner, bringing the holes a certain distance apart, also equidistant from the punch stem and in line with each other.

A FEW MULTIPLE JIGS.

By W. G.

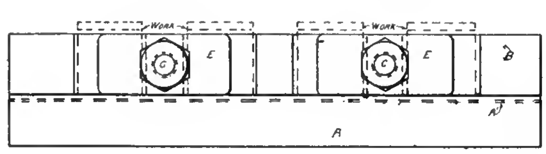
QUITE a number of multiple jigs do not, in actual practice, produce the expected results; this being very often due to one of two things, namely, the locating parts are so enclosed as to render the clearing away of chips a difficult and lengthy operation. Again, the method of holding work is often far too complicated, thus in many cases taking longer to insert and remove the work than to perform the machining operation. It must, of course, be admitted that these conditions cannot always be avoided, but in many cases a little forethought when designing, would mean elimination of the aforementioned troubles.

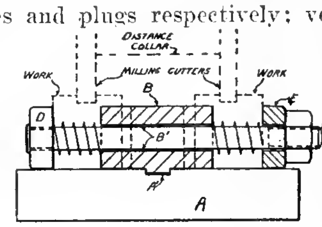
Slitting Jig.

The drawings herewith illustrate a few jigs of the multiple type that have in actual practice proved in every way satisfactory. Fig. 1 shows three views of a slitting jig. The base, part A, consists of a flat rectangular cast iron plate on the upper face of which is formed a tongue groove A^1 for the purpose of aligning the locating or work block B. This is made from a block of mild steel, the longitudinal sides being shaped away to form the eight vee grooves as shown. The said block is further provided with two transverse holes B^1 for receiving the clamp bolts C. These holes should be quite free to the bolts, as this compensates for any unevenness during clamping. Parts D and E are the clamps; these are preferably made from flat mild steel stock, and therefore require but little machining. It will be noticed that the clamps D are made integral with the studs C by screwing and riveting, while the clamps E are a sliding fit. Parts F are the clamp springs, their object being to keep the clamps in the outward position during insertion and removal of work.

Spanner Flats Milling Fixture.

Fig. 2 shows elevation and plan respectively of a fixture used for milling the spanner flats on the end of gland nuts; two settings of the fixture being required to complete the operation. The base G consists of a U-shaped iron casting, provided at its extremities with two feet or projections, G^1 and G^2; the use of which is to secure the base to the machine when in operation. The body H is also made from an iron casting, and consists of a circular disc, on the upper face of which is formed a square block or projection H^1 for carrying the work by means of the holes H^2 as shown. Parts I and J are the mild steel clamping plates and plugs respectively; very little need be said of these, beyond the fact that they (the plugs) should be a free fit in the transverse holes in the





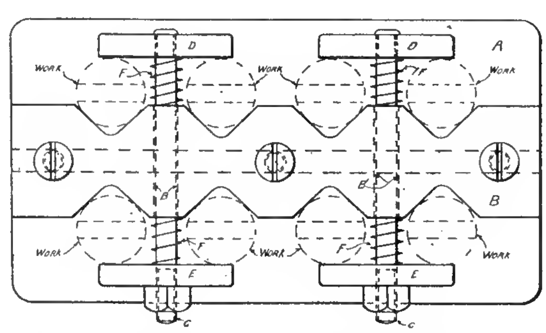


FIG. 1. SLITTING JIG.

block H^1, likewise the clamp stud K. Parts L are the clamp plate springs, and Part M is the fulcrum plug: this is for

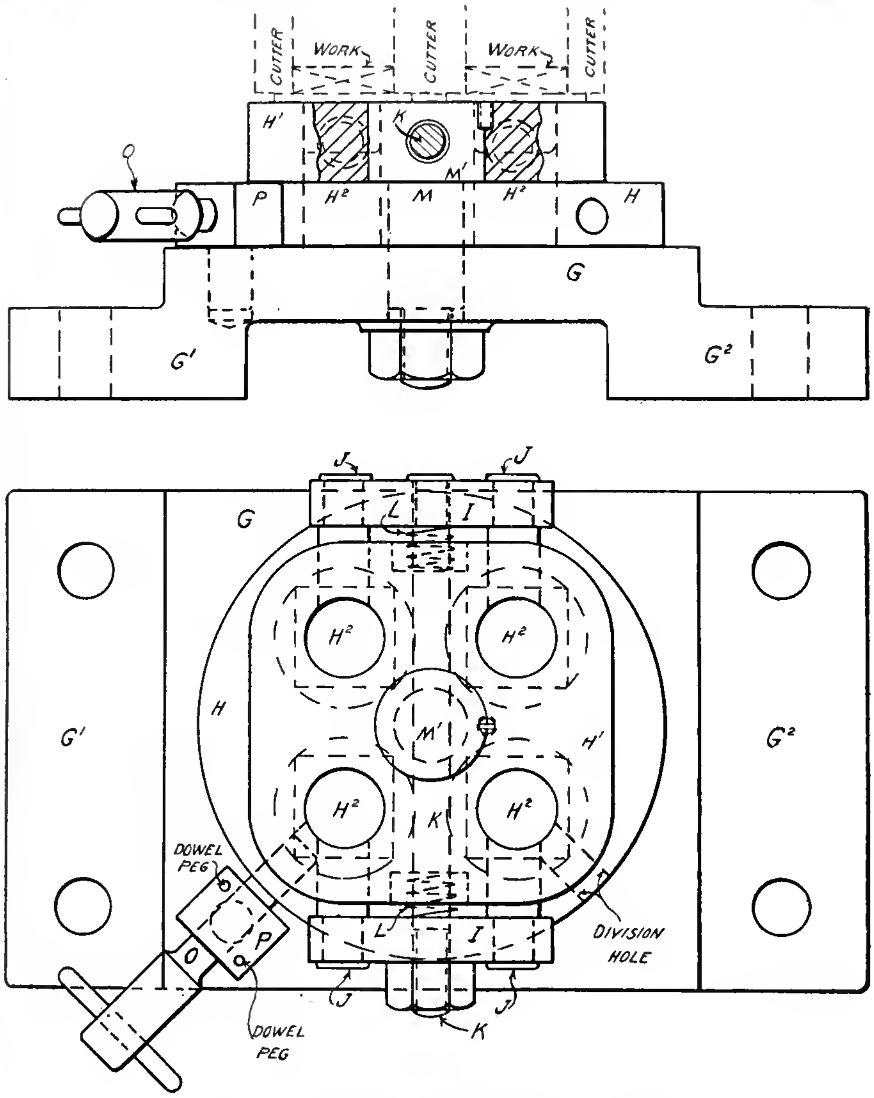

FIG. 2. SPANNER FLATS MILLING FIXTURE.

locking the body in position when in operation. The enlarged part M^1 should be made a tight fit to the central hole in the body, and the reduced part should be a sliding fit (not loose) to the hole in the base G. Indexing is carried out by means of the hardened plug O engaging with the index block P and the two holes at an angle of 90 dgs. apart formed in the periphery of the body H as shown.

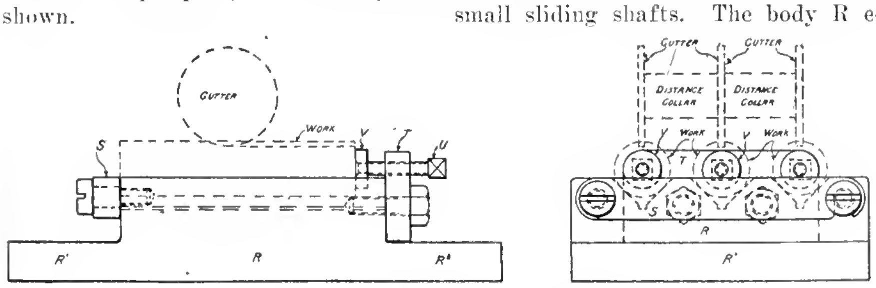

FIG. 3. KEY SLOT MILLING FIXTURE.

The sequence of operations is as follows: The first cut produces parallel flats on the sides of the work; the fixture is next withdrawn, and the index plug removed from the hole in the body H. The locking nut is then slackened off, thus leaving the body free for rotation, until the next hole in its periphery is brought into alignment with the index plug, which is reinserted, and the body locked ready for the next operation (finishing square.)

Key Slot Milling Fixture.

Fig. 3 shows side and end views of a simple fixture for milling key slots in small sliding shafts. The body R consists of a rectangular cast iron block provided at its base with two steps or projections R^1 and R^2, for securing it to the machine table. It is further provided upon its upper face with three vee grooves as shown, for locating the work. Part S is a mild steel thrust plate; it being made to swivel to facilitate cleaning away the chips from the vee grooves. The clamping plate T is also made from mild steel. It is rigidly secured to the body R; its object being to carry the three clamping pins U; these consist of ordinary set screws turned down at the end to receive the mild steel clamping discs V. The object of these latter is to prevent injury to the work when clamping.

It may be worthy of mention that in this particular case it was advantageous to use a separate clamping means for each part, as the overall lengths of the shafts were not particular within 3-32 in., yet it was essential that the length of keyslot from the plain end (uncut) should in each case correspond with the other. This latter was made possible by locating against the face of the thrust plate S by means of the set screws as shown.

THE IMPORTANCE OF CORRECT GATING.

By Arthur Smith.

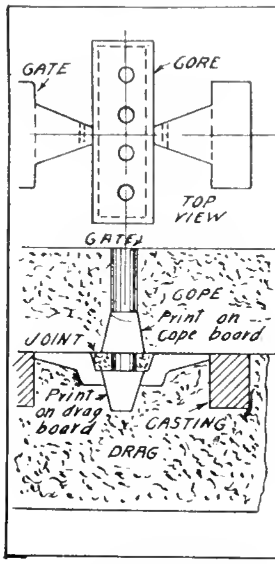
It is perhaps not an exaggeration to state that fully fifty per cent. of the castings proving defective in a foundry are the result, either directly or indirectly, of incorrect gating. A careful and efficient foreman will see that the moulders are provided with proper equipment in the way of flasks; he will insist upon the necessary sands and facings, and will insure that the mould is fully secured and vented, but will leave the location and size of the gates to the judgment of the mechanic.

Correct gating is an art, and it is unfortunate that so few moulders value it at its true worth. We are all aware that if any dirt at all occurs in a casting it will likely be found at or near the gate. Still, many mechanics will place the gate right against or upon a finished face, simply because it offers a convenient place for the metal to enter the casting. Another delusion is that a heavy casting must have large gates, sight apparently being lost of the fact that several small gates will fill the casting equally fast, while the runner box may be kept full at all times and the danger of slag and dirt going down materially reduced.

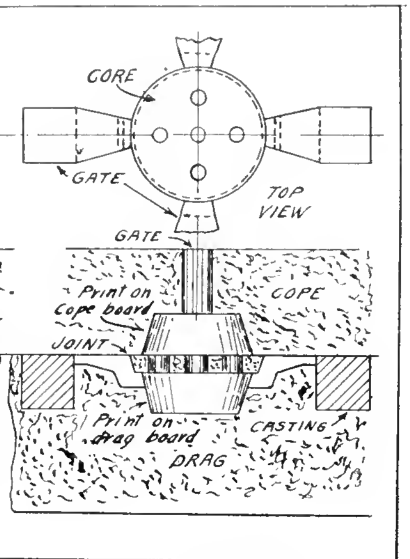
Top or "Pop" Gate.

Many moulders lean toward the top or "pop" gate. This is a round gate, 3/8 in. or 1/2 in. in diameter, placed directly on top of the casting, and in a great many cases it is a first-class arrangement. One of the principal objections to its general use, however, is that the metal falls continuously upon the face

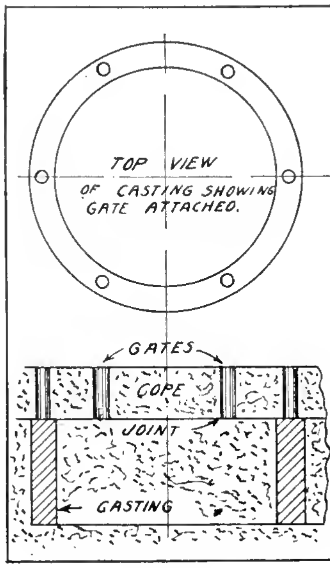
of the mould or core, and is apt to cause cutting or scabbing unless the mould is nailed where the metal strikes. In castings having flanges or pockets where a pool is almost instantly formed, the "pop" gate can not be improved upon.



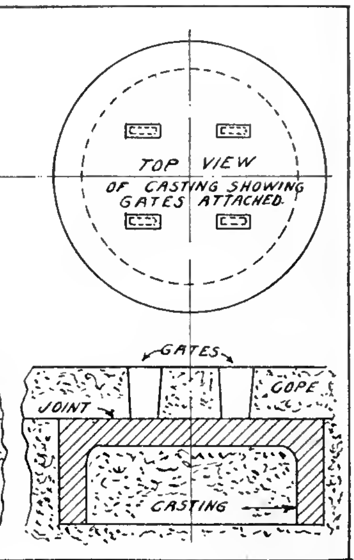
STRAINER GATE RECTANGULAR.



STRAINER GATE ROUND.



POP GATE.



STOVE PLATE GATE.

Flat or "Stove Plate" Gate.

The flat or "stove plate" gate is often used for light work with good results. This gate is usually ¼ in. or ⅜ in. in diameter by from 2 in. to 4 in. wide, and is placed directly on top of the pattern. As the name indicates, it is used extensively for stove-plate work, thin plates, etc. It is remarkable how fast one or two of these gates will take the iron, and the mould fills so rapidly there is little danger of cutting.

The "Strainer" Gate.

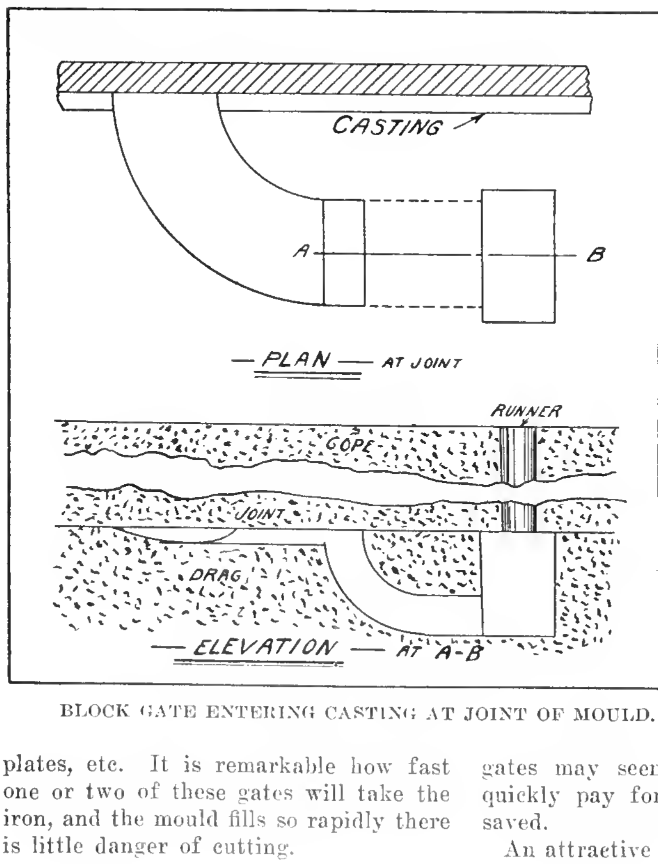
The "strainer" gate for small gated work is one of the most satisfactory that has ever come under the observation of the writer. When using this gate, the metal is strained through a perforated oil sand core, and it is almost impossible for any dirt to enter the mould. In a moulding machine shop, where the work is poured by foreigners, whose chief desire seems to be getting the iron out of the ladle, this gate is invaluable. While the initial expense of equipping machine boards with strainer gates may seem formidable, they will quickly pay for themselves in castings saved.

An attractive method of pouring heavy castings is through the "block" gate. This is a modification of the well known "horn" gate, and its success lies in the fact that the metal is so thoroughly screened there is very little likelihood of any impurities entering the mould. This gate may be made quite heavy, and engine beds weighing several tons are successfully poured with one block gate on each side of the main bearing.

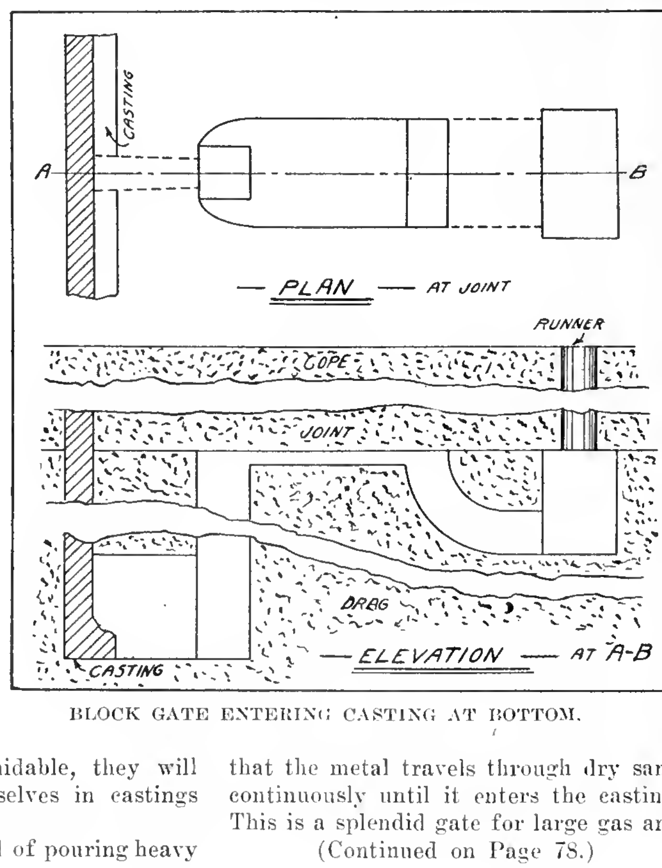
Gating Through the Core.

The old-fashioned method of gating through the core commends itself in many instances, and has the advantage that the metal travels through dry sand continuously until it enters the casting. This is a splendid gate for large gas and

(Continued on Page 78.)



BLOCK GATE ENTERING CASTING AT JOINT OF MOULD.



BLOCK GATE ENTERING CASTING AT BOTTOM.

Arithmetic for the Machinist and Workshop Operative

By J. H. Rodgers

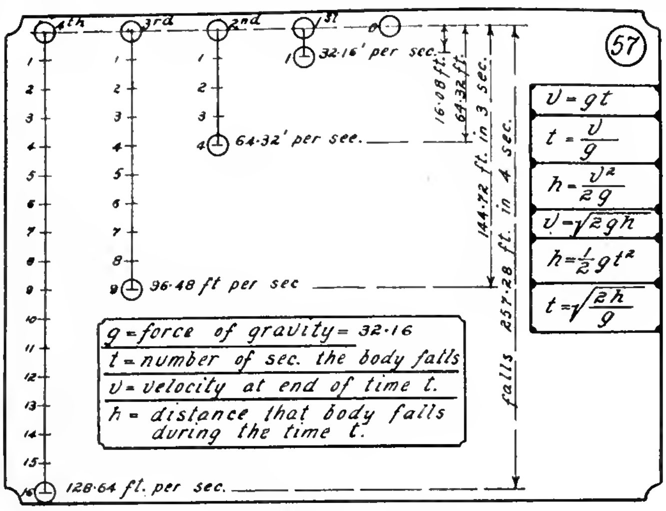
It will be found by those who have followed the previous lessons and profited by them that the various practical applications can now be easily observed, applied and appreciated.

GRAVITATION.

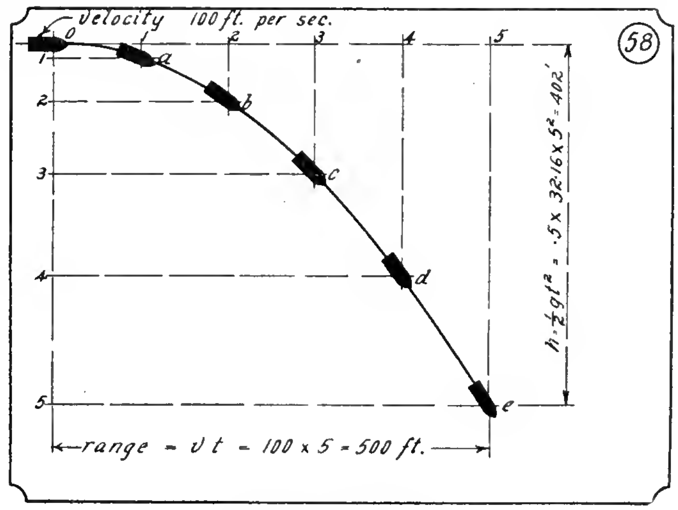
GRAVITATION is the force which is continually acting between two bodies tending to draw them together. The downward pressure of a body (usually termed the weight) is the attraction of the earth toward that body. The attraction between the earth and any body, at or near the surface, is called the force of gravity, and this force will always be the same. By formula:

$$\text{Mass} = \frac{\text{weight of body}}{\text{force of gravity}}, \text{ or } m = \frac{w}{g}.$$

The general laws of weight are that bodies weigh most at the surface of the earth or sea level; that below the surface, the weight decreases as the distance to the center decreases; and that above the surface, the weight decreases weight of a body, the distance above or below the surface must be so great that for all practical purposes the differences need not be considered. If a number of objects irrespective of their size, shape or weight, were allowed to fall within a vacuum, it would be found that each object falls through the same distance in the same time. If, however, the same objects were dropped from a certain



ARITHMETIC CHART 57.



ARITHMETIC CHART 58.

always acts in a straight line between the center of the body and the center of the earth.

The attraction between the earth and a body (and therefore the weight) varies for different locations upon the earth's surface. It is slightly less, above and below, than at the sea level, but if the weight of any body at any place be divided by the force of gravity at that place, the ratio will be the same. This ratio is called the mass of the body, and as the square of the distance increases. By formula, when

d=distance between the centers of the earth and the body.

R=approximate radius of the earth=4,000 miles.

w=weight of body at given distance above or below the surface.

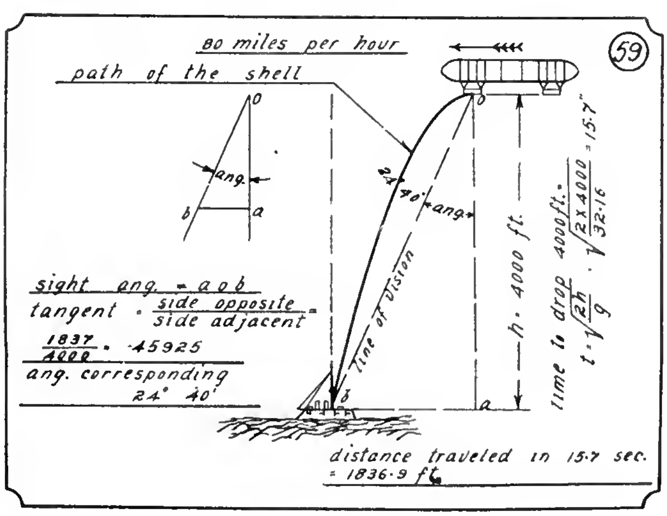
W=weight of body at the surface.

Below the surface:—$wR=dW$.

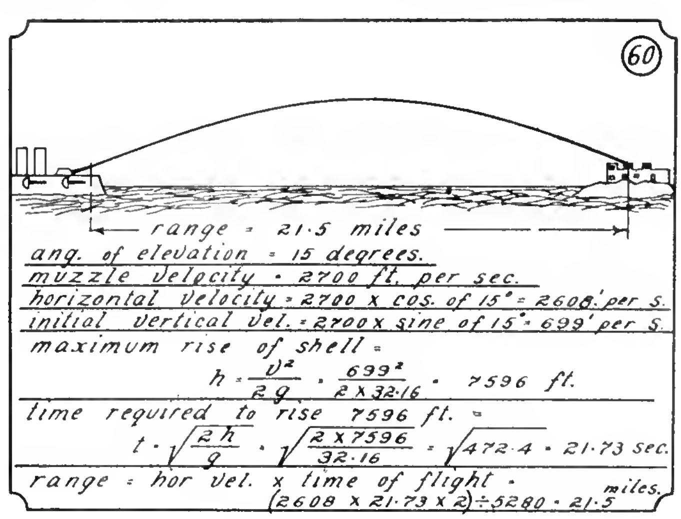
Above the surface:—$wd^2=WR^2$.

To have any material effect upon the height in free air, the one offering the least resistance to the air would reach the ground first, but if the shape and size of each were the same they would all descend the same distance in approximately the same time.

All bodies being attracted toward the earth with the constant force of gravity will gradually increase their velocity until brought to a state of rest. This increase in velocity is called acceleration. The velocity of a falling body due



ARITHMETIC CHART 59.



ARITHMETIC CHART 60.

to acceleration is the velocity at the end of one second multiplied by the number of seconds.

The acceleration of a falling body is slightly greater at the poles than at the equator, but for most practical purposes the constant 32.16 is generally used; that is the velocity of a falling body at the end of the first second is 32.16 feet per second. At the end of a fall of four seconds, the velocity would be, $32.16 \times 4 = 128.64$ feet per sec. (See Chart 57.)

It has been found by experiment that a freely falling body will fall 16.08 feet during the first second, and for a greater fall the distance will equal 16.08 multiplied by the square of the time in seconds, or

$h = \frac{1}{2} gt^2$ when

h=height of fall.

g=force of gravity=32.16.

t=time of fall in seconds.

If the machine of an aviator turn turtle at a height of 500 feet and fall

$$h = \frac{1}{2} gt^2 = \frac{1}{2} \times 32.16 \times 5^2 = 402 \text{ ft.}$$

The range will equal the velocity multiplied by the time of flight or

$r = vt = 100 \times 5 = 500$ ft. (See Chart 58.)

If a dirigible airship is travelling at a rate of 80 miles per hour, and at a height of 4,000 feet: what distance in advance must the explosive be allowed to fall to hit its objective?

To find the horizontal velocity of projectile at time of discharge, resolve the speed of airship into ft. per second.

$$\frac{80 \times 5280}{60 \times 60} = \frac{352}{3} = 117\ 1\text{-}3 \text{ ft per sec.}$$

Time required to drop 4,000 ft. =

$$t = \sqrt{\frac{2h}{g}} = \sqrt{\frac{2 \times 4{,}000}{32.16}} = 15.7 \text{ sec.}$$

Distance travelled in 15.7 sec. =

$117 \times 15.7 = 1836.9$ feet.

= 698.8 ft. per sec.

The greatest height to which the shell will rise =

$$h = \frac{v^2}{2g} = \frac{699^2}{2 \times 32.16} = 7596 \text{ feet.}$$

Time required to rise 7,596 ft.——

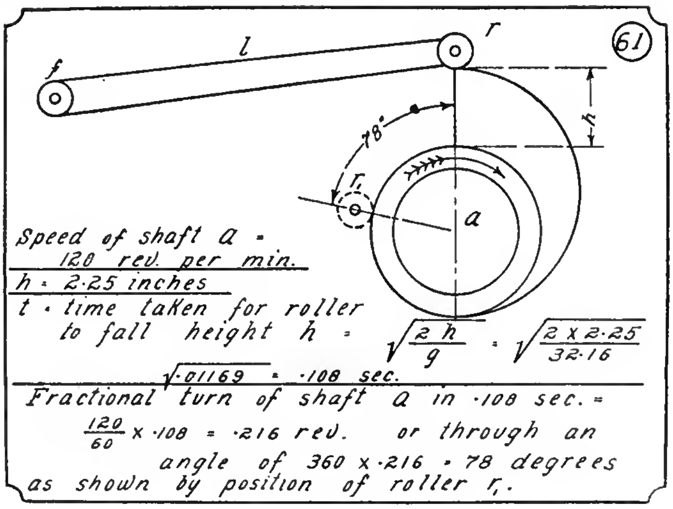
$$t = \sqrt{\frac{2h}{g}} = \sqrt{\frac{2 \times 7596}{32.16}} = \sqrt{472.4} = 21.73 \text{ sec.}$$

Then range = horizontal velocity multiplied by the time of flight =

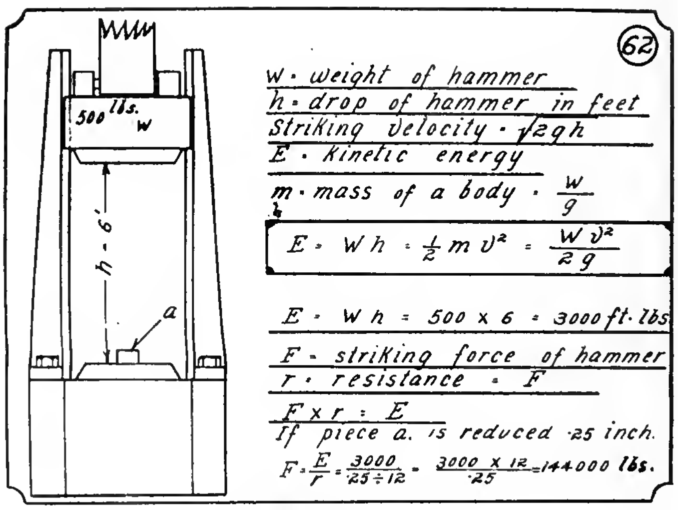
$2608 \times 21.73 \times 2 = 21.5$ miles.

In the sketch of the cam, roller and arm in Chart 61, the shaft A travels at a speed of 120 rev. per min., in the direction of the arrow; at what point on the cam will the roller strike, friction being neglected? Time taken for roller to fall 2.25 inches or .1875 feet =

$$t = \sqrt{\frac{2h}{g}} = \sqrt{\frac{2 \times .1875}{32.16}} = 108 \text{ sec.}$$



ARITHMETIC CHART 61.



ARITHMETIC CHART 62.

freely toward the ground, at what velocity will it strike the earth, allowing a reduction of 15 per cent. in acceleration due to the resistance of the air? By formula

$$v = \sqrt{(2gh)} = \sqrt{(2 \times 32.16 \times 500)} = 179.3 \text{ ft.}$$

Then $179.3 \times .85 = 152$ ft. per sec.

If a baseball be thrown vertically upwards, and five seconds elapse before it returns to the ground, to what height did it go, and what was the initial velocity? As the total time elapsed was 5 seconds, the time of fall was $5 \div 2 = 2.5$ sec. By formula

$h = \frac{1}{2} gt^2 = \frac{1}{2} \times 32.16 \times 2.5^2 = 100.5$ ft., and

$v = gt = 32.16 \times 2.5 = 80.4$ ft. per sec.

If a projectile be discharged in a horizontal direction at a velocity of 100 ft. per second, what must be the height of gun if shell strikes the ground at the end of the fifth second, and what is the range? As gravity acts constantly irrespective of the velocity, the height=

As this distance could not be readily reckoned at such a height, the angle corresponding must be found. As will be seen from Chart 59, the line of vision ob forms the hypotenuse of the right triangle oab of which the sides are the elevation and distance travelled respectively. The sight angle = a o b, then

$$\text{tangent} = \frac{\text{side opposite}}{\text{side ajacent}} = \frac{1837}{4000} = .45925,$$

and angle corresponding = 24° 40 minutes.

If a naval gun (Chart 60) be discharged with a muzzle velocity of 2,700 ft. per sec. at an elevation of 15 degs.; what will be the approximate range, the resistance of the air being neglected? Resolving the angular velocity into the horizontal and vertical components we have horizontal velocity =

$2700 \times \cos.$ of $15° = 2700 \times .96593 = 2608$ ft. per sec.

Initial vertical velocity =

$2700 \times \text{sine of } 15° = 2700 \times .25882$

At 120 rev. per min., the shaft will revolve in .108 sec.

$$\frac{120}{60} \times .108 = .216 \text{ of a revolution,}$$

or through an angle of

$360 \times .216 = 78°$

If the head of a drop hammer, weighing 500 lbs. fall a distance of 6 feet, reducing a piece of metal ¼ of an inch in thickness; what is the kinetic energy and the striking force of the blow? The kinetic energy of a falling body is the weight of the body multiplied by the distance in feet through which it falls, or

$E = Wh = 500 \times 6 = 3000$ ft. lbs.

The striking force of a falling body equals the resistance, and the product of the two equals the kinetic energy, then, as the resistance or compression of the metal = .25 inch, we have

$$F = \frac{E}{r} = \frac{3000}{.25 \div 12} = \frac{3000 \times 12}{.25} = 144{,}000 \text{ lbs.}$$

FACULTY OF SPOTTING PLANT IMPROVEMENTS.

By James E. Cooley.

We are spoken of as "creatures of habits." In repeating certain acts, in time we become sprinkled with a blindness, so that we do not realize when we are doing these things, and why we are doing them; we become unconscious of the real motive behind our efforts. This is plainly what is called "being in a rut." We cannot see and will not see until circumstances or someone points the way out for us.

Opportunity Always Present.

No person, no place, or institution escapes from this peculiar lethargic state, and the machine shop is included in the list. Where so much depends on saving time and reducing costs, it is hardly believable, until we are shown the facts, how many foolish and wasteful acts are done in the course of one's daily labor. A stranger looking in at the shop windows will see many things, and wonder why they are done. The fact of the matter is that while one can see easily enough from without, none apparently can see from within. It is only as we step outside that we can see inside a circle.

Repitition, doing the same things over and over, has the effect of deadening the brain's activity, and lessening the power of being able to think along new lines. If we study rut-making conditions we will become gradually enlightened and see the necessity of periodically changing the regular order of the things we do, for the mere sake of keeping clear of getting in a rut.

Being Alert to Opportunity.

There is no known method of advancing except by watching for opportunities to improve things. The reason why we do not go ahead and do things is because the impressions we receive do not go in deep enough to affect us, to stir us up to act; even having started something, we soon lose sight of the object we strive for. We adopt means for certain ends, then reverse the order so to speak, shift the thing around and preserve and uphold the means regardless of what the ends are. We become sprinkled with a blindness or what is the same thing, we enter into a state of "forgetfulness." The trouble is as before stated, our impressions do not get in deep enough, so that we wont' forget, so that we will remember what we are doing and why we are doing it. If we can get this fact strongly enough imbedded in our minds we seldom will get into a rut, or getting there, will know when is the opportune time to jump out.

Typical Examples.

A few cases are here cited to show what this rut-evil really is. A machine for grinding was bought and installed in a corner of a room by itself. In order to keep the machine clean and free from dust when not in use, a few yards of cloth were bought to cover it entirely. When workmen desired to use the machine they would pull off the cloth, double it up any old way and toss it on the bench, regardless of whether the bench was clean or not. When their job was finished they would throw back the cloth on the machine, without noting which was the top or dirt-covered side of the cloth. In time the cloth became soiled on both sides, and as much dirt was placed on the machine as was kept off. This repetition of removing and replacing the cloth was kept up for years.

If a "notice" had been put up stating what the cloth was for, which side was to be placed over the machine, and that it was to be taken off carefully and folded, the machine-users might have received a deep enough impression of their duties. One would think, however, that common sense was sufficient to indicate the proper thing to do in a matter of this kind without the aid of printed instructions. No, we can never depend on suppositions. While no great amount of profit was lost in this practice, it was a foolish action each time it was repeated.

A certain section of a factory was set apart for making up small shipments. Under a work-bench was placed several kegs of nails, one behind the other. Each time the packer wanted nails he had to reach down and rummage in the several kegs before he could find the size nails required. It would seem that the waste of this time, and constantly running into this inconvenience would have brought some enlightenment to the workman to the end that it would have led him to have the kegs placed on a bench purposely made, and have each size or sample of nail placed on the outside of each keg. This idea failed to materialize, however, as similar ideas fail to come to us. This inconvenience would never be discovered, and this and other wasteful methods of doing things would never be found out, unless a systematic study of each detail connected with machine-shop work was carried out.

A sweeper was given a long handle brush to sweep the floor of a room containing special machinery, so as not to raise too much dust. When he was through with it he stood it up against a post in the room. The sweeper left, other sweepers came after him, and each one who used that brush placed it back in the same identical place against the post. Workmen walking near it knocked the brush down, then picked it up again, and as many times as that long handle brush was used, and, as many times as it was knocked to the floor, it never occured to anyone to plug a hole in the end of the handle, loop a string through it and hang it to a peg.

Criticism Beneficial.

The reason why we act, why we make changes, is because someone suggests the idea to us to do so, otherwise we never make the effort. We need criticisms as well as suggestions, we need a lot of them, but we are dependent on one another for them, we have got to "see" for each other. Throughout each factory there are useless and wasteful practices blindly and thoughtlessly followed. Each detail needs to be carefully looked into. Disorder is found in the way some things are kept, and things are done that should never be done as they are. For example, crowbars and skid-rolls are kept in a corner or behind a door where they tumble down and workmen stumble over them. An upright-bin, sectioned off, should be built, and these materials placed in it. Again, a helper shovels up the cast-iron chips from under machines and pans into an open box, causing clouds of dust to fly upward, which gets into the belts and bearings and settles on everything. The box should be covered over, having an opening sufficient for the shovel to enter and thus keep the dust down.

Systematic Study of Detail.

Several changes such as these are required in many factories. The need only, is to develop the faculty to see them. This is best acquired by systematically studying each detail and improving it.

THE USE OF FLUX IN THE BRASS FOUNDRY.

By R. Micks.

THE intelligent use of flux in melting brass and other alloys has been proven beyond doubt to be a great help to foundrymen in producing sound castings from the different alloys, and, while in some foundries the flux question is overdone, there are still some brass founders who do not seem to see the advantage of using a flux when melting their metals. The experience of experts along these lines has shown very clearly that the right flux for the right metal when it is used at the proper time in the melting will not only produce better castings, but will also save metal.

Copper.

Good sound castings cannot be produced from copper when it is melted alone, and more chemicals have been tried and more different fluxes proposed for this metal than for any other used in making alloys. The difficulties of securing sound copper castings are due to oxygen-nitrogen and oxygen containing gases, and to overcome this trouble, it is necessary to use a flux or deoxidizing agent.

The flux now generally acknowledged as the best for copper is boron sub-oxide. This flux has a high affinity for these gases, but no affinity for copper. Potassium-ferro-cyanide has also been found to give good results as a flux for copper. Many foundrymen prefer, however, to use deoxidizing agents, such as silicon-copper-magnesium, phosphorus, etc.

Brass and Bronze.

For brass and bronze, common salt is almost universally used as a flux, and some founders claim to have got the best results with rock salt. The action of salt on these metals is that it forms a protective coating and prevents oxide of copper from forming. To obtain the best results from salt as a flux, it should be added when the first metal in the crucible begins to melt, a handful to the ordinary crucible being sufficient. The brass founder will find that, although cheap, salt will improve the quality of his castings whether he is using new metal or scrap. The metals should be kept well covered with charcoal during the melting process.

Aluminum.

For years, aluminum was melted without a flux or covering, as charcoal, on account of the lightness of aluminum, was almost sure to become mixed with the metal and cause black spots in the castings. Chloride of zinc has proved to be the most valuable flux for aluminum. The action of this flux when used on aluminum is that the zinc combines with the oxygen, which is taken up from the aluminum oxide, and forms zinc oxide. This is then skimmed off, together with the aluminum chloride, which is also formed in the reaction, when the flux is added. A piece of chloride of zinc the size of a walnut is sufficient for 50 lbs. of melted aluminum, and when dropped on the thick mass of dross, covering the surface of the melted aluminum, it will be quickly cleared. The metal should next be stirred, after which its surface will be found perfectly clear. Good, clean castings will be produced, but care should be taken not to raise the temperature any higher than is necessary, as melted aluminum should be protected from the air as much as possible.

Nickel.

The flux used for nickel, and the one that has given the best results, is a mixture of lime and fluor-spar, composed of 3 parts lime and 1 part fluor-spar. The lime should be slake, and it should be mixed with the fluor-spar and then be allowed to become solid, when it can be broken into small pieces for use. While fluor-spar alone acts all right as a flux for nickel, it attacks the crucible, affecting the clay in the crucible mixture in such a manner as to dissolve it, then as nothing but the graphite remains, the crucible goes to pieces when grasped by the tongs. Although the lime counteracts the action of the fluor-spar on the crucibles to a certain extent, they very seldom last more than five or six heats in melting nickel.

Turnings, Washings, Grindings, Etc.

As a flux for melting turnings, washing and grindings, nothing excels plaster of paris, it being not only a first-class flux for this purpose, but also having the advantage of being very cheap. Its main feature as a flux in melting these materials is that it dissolves all foreign matter that may be present in the form of sand, oxide, or slag. It melts quickly and forms a liquid slag, and has no bad effects on the crucible. About five pounds of Plaster of Paris mixed with a crucible full of turnings, washings, grindings, etc., should give desirable results. The metal should be allowed to melt in the usual manner, and if the slag is not fluid enough at the conclusion of the melt, more plaster of paris should be added. When the metal is ready to pour, do not attempt to skim, as the slag will rise to the top when the metal is poured into the ingot moulds, and when they are cool the slag of the plaster of paris can easily be detached by a few blows from a hammer.

COMING CONVENTIONS.

American Foundrymen's Association, Atlantic City, N.J.—Sept. 27-Oct. 1.

Foundry and Machine Exhibition Co., Atlantic City, N.J.—Sept. 25-Oct. 2.

THE IMPORTANCE OF CORRECT GATING.

(Continued from Page 74.)

air cylinders cast on end, the method being to cut the gate through the centre of the barrel, a vent being rammed in each half of the core.

The Runner Box Feature.

Even when the utmost care is exercised in gating, the effectiveness of the gate is often discounted by the sloping and spilling of the metal in the runner box when beginning to pour. To guard against this, some founders place a dry sand runner box on top of the mould. In this runner are placed one or two strainer cores, which collect all dirt or slag before it can reach the gate. This runner core is simple to make, and an ordinary coremaker can turn out a great number in the course of a day. One is surprised at the amount of dirt gathered by the strainer cores, a portion of which would almost of necessity enter the gate.

Gating at Heaviest Section.

Some moulders make a practice of always gating a casting at its heaviest section. While this may be quite convenient, it is decidedly wrong, for the reason that the gate keeps the metal alive at this point so long that a spongy condition results. Unfortunately this is not detected until long after the casting leaves the foundry, and many weak castings are laid to faulty design where, with the proper arrangement of gates and risers, they would be sufficiently strong for the purpose intended.

Independent Line of Sight.—An advantage the Allies have over the Germans in the matter of field artillery is that the former have adopted the "independent line of sight" for sighting their guns. In this arrangement, the gun is mounted on an intermediate carriage, and on this carriage the sight is fixed. In laying the gun, the operator revolves the intermediate carriage screw until the sight glass is on the target, when the gun will also be on the target except as regards elevation. The gun is then given elevation separately. The layer, therefore, does not have to attend at all to elevation, another man being told off for this duty.

Winnipeg, Man.—The Board of Control have awarded the contract for the supply of a steam boiler to Babcock & Wilcox, Montreal, at $2,500.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

HEAVY DUTY DRILL PRESS, WITH COMPOUND TABLE.

This heavy duty drill press is a product of the Colburn Machine Tool Co., Franklin, Pa. It has a capacity to the full cutting edge of 2-inch high speed drills in solid steel, and is of very rigid construction. Shafts are of high carbon steel and all bearings are bushed with bronze and provided with a positive and reliable method of oiling. All speed and feed changes are obtained through positive gearing by means of handles and levers conveniently located within easy reach of the operator.

The drive is through a constant speed belt on to a single pulley. Speed changes are obtained through selective sliding gears controlled by levers within easy reach of the operator. No countershaft is necessary, as a pair of tight and loose pulleys are mounted directly upon the main driving shaft of the machine, parallel to line shaft.

Six changes of speed are obtained, and never more than two pairs of gears are in mesh at any one time. All changes are made by sliding gears, no clutches being used. Splash lubrication is employed and gears and bearings receive a constant flood of oil.

The spindle is of forged high carbon steel. The thrust is taken on "Hess-Bright" ball thrust bearings spherically seated, which provide for any slight deflections or mis-alignment and distribute the load equally over the full circle of balls. Spindle has a traverse of 16 inches and a No. 5 Morse taper socket.

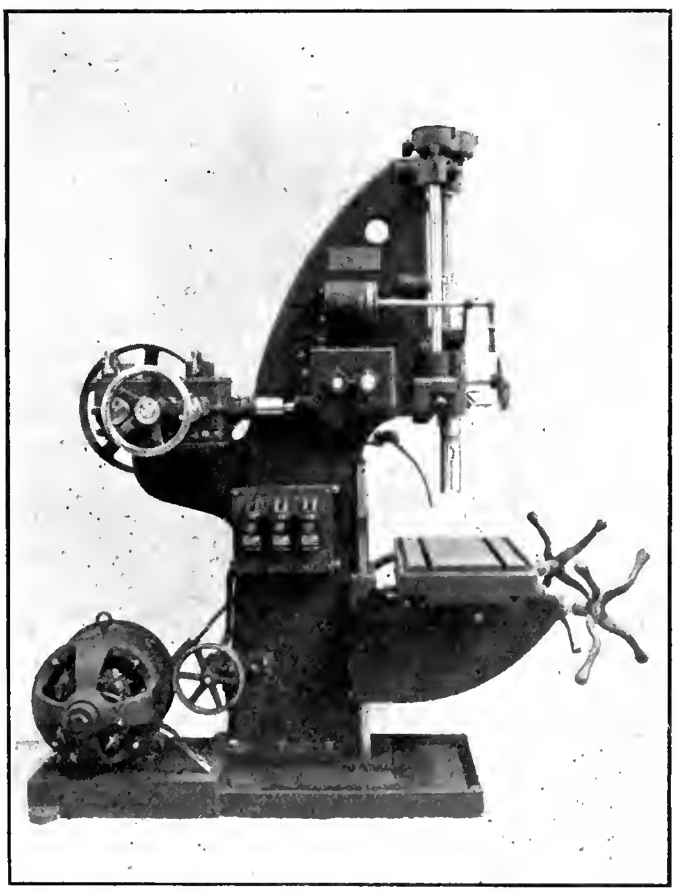
The main spindle driving gear and its pinion have helical teeth. All gears not running in oil bath are covered with dust-proof guards and special grease cups are provided which deliver the lubricant directly on to the teeth. Three spindle feeds are available.

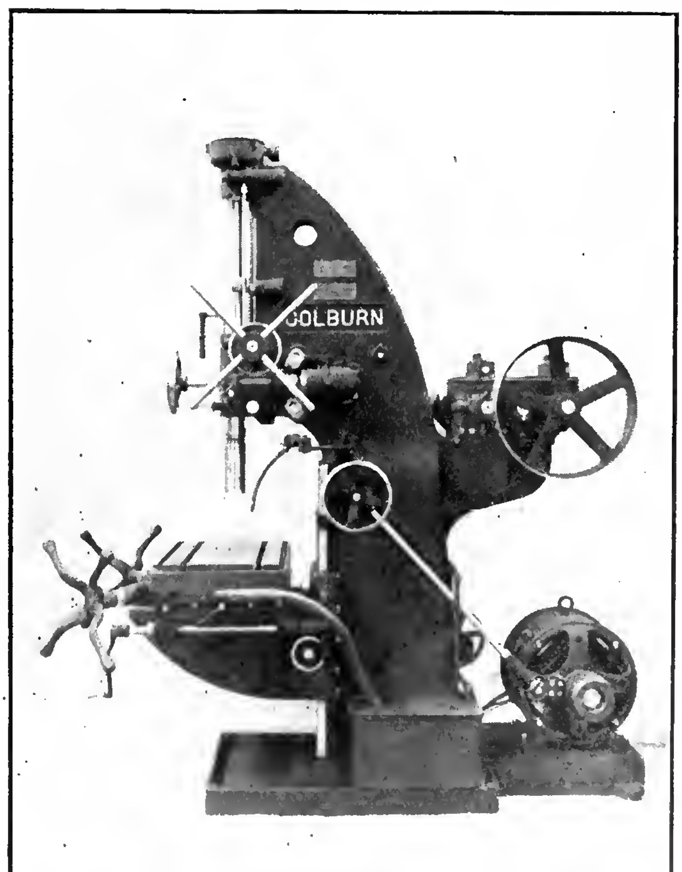
An automatic trip is furnished for tripping the power feed at any desired depth. A final safety trip is also furnished to disengage the feed when spindle has reached its lowest position, thus preventing possible accident.

Quick traverse of the spindle is obtained through four capstan handles, and power feed can be instantly changed to hand feed, or vice versa, by sliding the hand wheel shaft either in or out, thus engaging or disengaging a positive clutch connected to feed train of gearing. A safety device is provided to protect the feed mechanism, which will shear a pin before doing any damage.

The standard table is of the bracket type, gibbed to the column with extra long upright bearing. It has a vertical adjustment of 24 inches by means of rack and pinion and worm and worm wheel. The table can be bored for bushings to support the ends of boring bars up to 3 inches in diameter. The working surface is 18 x 20 inches, and a large oil pan is provided on both sides and in front.

The compound table is not an attachment to the regular table, but consists of a special knee with a table having a rapid movement through spiral worm and rack of 20 inches longitudinally and 8 inches crosswise. Capstan handles are so arranged that the operator standing directly in front of the machine can manipulate the table in both directions without moving from his position. A large oil pocket is cast on each end and a cored opening running entirely through the table drains the lubricant from the





HEAVY DUTY DRILL PRESS WITH COMPOUND TABLE.

left hand to the right hand pocket, and from there it is piped through a flexible tube back to the tank. Grooves along the edges of the table also drain the lubricant from the surface. The working surface of the compound table is 18 inches wide by 30 inches long. An oil pump attached directly to the machine is driven by a belt from pulley on speed box shaft.

The tapping device consists of a pair of friction clutch pulleys mounted on the main driving shaft of the speed box, and, by means of open and cross belts, made to run in opposite directions. To accomplish this the driving shaft is made extra long, and is supported at its outer end by a substantial journal box on the end of a bracket. The clutches are controlled by the lever directly in front of machine. The reversing mechanism of this tapping device being placed directly on the prime mover instead of on the drill spindle, excessive strain on the parts is greatly reduced.

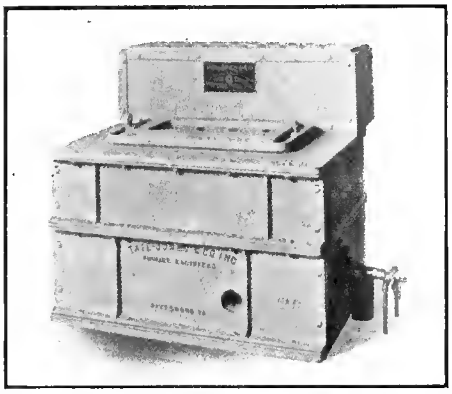
When the machine is to be used for tapping large diameters it is equipped with a tapping hood. This device relieves the strain on the driving key in the spindle gear. The excessive power required to drive a large tap exerts such a pressure on the side of this key that it is almost impossible for the spindle to feed, and this causes the tap to tear the threads and spoil them. With the tapping hood, the friction is reduced to the minimum, since the power is applied through a bar having several times the leverage of the ordinary key in the spindle gear.

With a constant speed motor, the same speed changes are obtained as with regular drive. A "Reliance" motor is mounted on an extension of the base at the rear of the machine, where it is entirely out of the way. A belt drive direct from motor to driving pulley is recommended, and any size or make of constant speed motor from 5 to 10 h.p. can be used, depending upon the work to be performed.

The floor space occupied is 77 in. by 34 in., the height 110 in., and the net weights with plain and compound tables respectively are 3,100 lbs. and 3,700 lbs.

PREHEATED LEAD BATH FURNACE FOR SHELLS.

THE furnace here illustrated has a lead bath, 12 in. wide, 24 in. long, and 12 in. deep. At one end of the bath there is arranged a suitable pocket to accommodate the pyrometer couple. The lead bath proper is covered by a cast iron plate, through which are eight openings for inserting shells. The furnace is specially designed for Russian type shells, these being placed in the already mentioned holes open end up. Plugs in these open ends force the shell down into the lead, until each plug strikes the top plate.



PREHEATED LEAD BATH FURNACE FOR SHELLS.

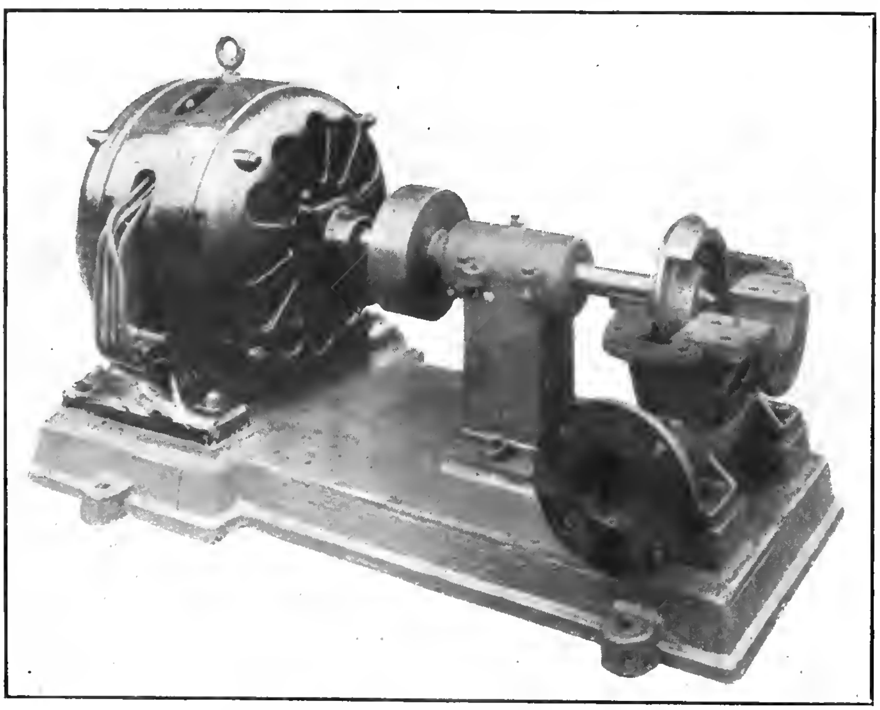
There is sufficient bath in the pot, so that when eight shells are inserted the surface of the lead is up to the bottom of the plate covering the pot, and the shell is immersed to within about 1 in. of its top. As these shells are nosed after the heat-treating operation, this 1 in. receives heat treatment at that time.

In the preheating chamber to the rear of the furnace there is room for twenty shells. The hot gases from the combustion chamber of the furnace pass through this preheating chamber, heating up these shells, and thus taking advantage of considerable heat that would otherwise be wasted.

A distinctive feature of this furnace is the fact that the combustion chamber is entirely separated from the chamber in which the pot rests, the heat passing from one chamber to the other through suitable openings and being distributed evenly over the surface of the pot. The design eliminates excessive heating of the pot at any one point, thereby increasing the life of the pot itself and the furnace proper. Tate-Jones & Co., Pittsburg, Pa., manufacture this product.

CENTRIFUGAL PUMP FOR THICK LIQUORS.

THE cut herewith shows a high efficiency type of centrifugal pump suitable for handling liquors containing large quantities of solids, chemicals, wood pulp, or gun cotton pulp solution. The impeller is designed along high efficiency lines, but has very wide passages in proportion to its capacity, the design being such that, in spite of these wide passages, a high efficiency is obtained without having the pump characteristic such as to produce a heavy overload on the driving motor when operating at pressures below the rated pressure.



CENTRIFUGAL PUMP FOR THICK LIQUORS.

The pump has a horizontally-parted case which facilitates access to the interior for convenience of inspection, cleaning and repairs. The pedestal bearing shown is equipped with two ball bearings operating in a housing packed with a non-fluid oil or light ball-bearing grease. These are so arranged as to carry not only the radial load, but any thrust that may come on the pump in either direction. The impeller, however, is provided with a balancing ring so as to secure approximate hydraulic balance. On account of the large passages through the impeller, the pump is also very suitable for pumping sewage, as solids which would ordinarily choke up a small capacity impeller pass freely through the pump.

The particular pump shown is driven by a single phase motor, and, for the purpose of keeping down the starting current, a special centrifugal clutch coupling is provided, which allows the motor to come up to speed before the load comes on the motor. Either this type of coupling or the standard type of flexible coupling with steel pins and rubber bushings is furnished. This type pump is particularly suited for handling nitrated cotton liquors in connection with the manufacture of gun cotton.

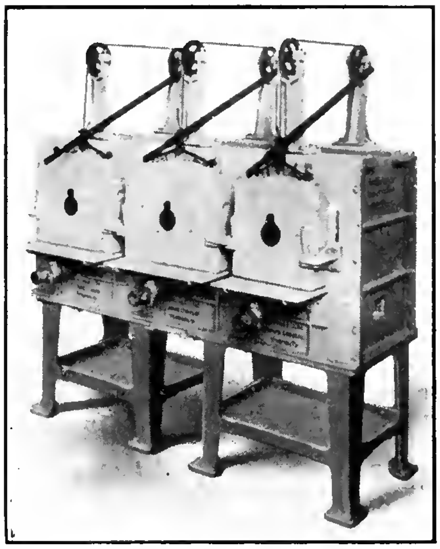
The pump is manufactured by the D'Olier Centrifugal Pump and Machine Co., Philadelphia.

VERTICAL TYPE SUCTION OILER.

TO meet the demand for an oiler embodying the same principle as their universal type (a description of which appeared in these columns some time ago), the Hanna Engineering Works, Chicago, have developed the vertical type shown in the accompanying illustration. The operation of these oilers is entirely automatic, because suction action takes place immediately the air moves and ceases the instant the air is shut off. The necessary amount of lubricant at the proper place and time is, therefore, realized. A chamber containing an absorbent is kept saturated from another large oil storage chamber surrounding it, and air passing through the lubricator becomes sufficiently charged with oil to properly lubricate all surfaces with which it subsequently comes in contact.

VERTICAL TYPE SUCTION OILER.

The universal type oiler can be attached to air line in any position, operating equally well in any plane or angle, and can be filled in no matter what position. The vertical type, on the other hand, can be used only in the position shown. These oilers are made with $\frac{3}{4}$-inch, 1-inch and $1\frac{1}{2}$-inch pipe connections.



THREE-CHAMBER DIE-HARDENING FURNACE.

THREE-CHAMBER DIE-HARDENING FURNACE.

THE description and illustration refer to a three-chamber die-hardening furnace manufactured by Tate-Jones & Co., Pittsburg, Pa. It consists of three distinct separate chambers, two of which are 18 in. wide, 18 in. deep, and 10 in. high. The third chamber is 12 in. wide, 18 in. deep, and 10 in. high. Each has a separate combustion chamber located underneath and separated by a fire brick slab, the heat passing from the combustion chamber through long narrow slots at the sides of this slab into the heating chamber, giving a furnace of semi-muffle construction. Each chamber is fired independently by natural gas or fuel oil burner. Compactness is a feature of the arrangement, and for die work, where long soaking preheating heats are desired before bringing up to the final hardening temperature, special usefulness is claimed.

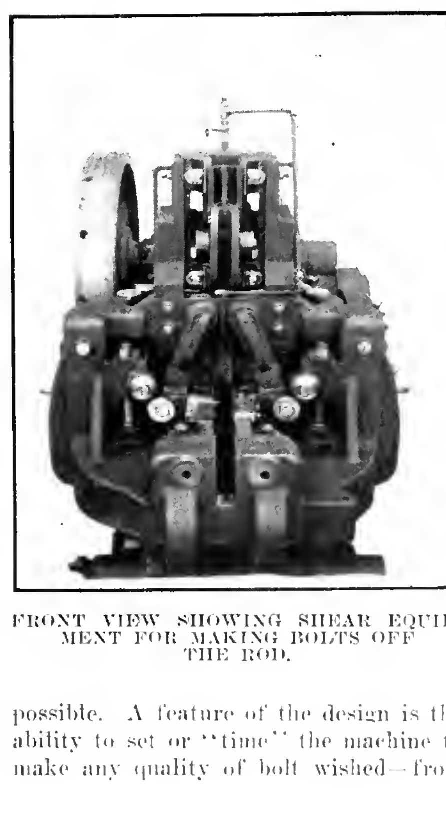
With this furnace, two chambers can be used for preheating and one chamber for hardening, or the three chambers can be used independently for entirely different work. A lever arm is fastened to the rear sheave bracket, and is attached with a suitable sliding arrangement to the lifting links on the door, so that the door can be readily raised and lowered by the movement of this lever. The counterweights for each door drop in the rear of the furnace.

NEW HAMMER BOLT HEADING MACHINE.

IN line with their adopted policy of developing bolt and nut machinery, in which hard manual labor is reduced to a minimum, the National Machinery Co., Tiffin, Ohio, have perfected, and are offering a new type of "hammer" bolt heading machine, termed the "National Continuous Motion Semi-Automatic Hammer Header." This machine is for making square, hexagon and tee head bolts from heated stock, and the following illustrations show some of the features embodied in the design.

About 60 per cent. of the square, hexagon and tee head bolts manufactured are the product of the "hammer" type of bolt header: and the aim of this new design machine is to effect the gripping, starting and stopping movements automatically, so as to free the operator of this labor and enable him to devote his entire attention and energy to feeding the machine. The design has not stopped here, however, for not only are these movements accomplished mechanically and automatically, but the main shaft, heading slide and hammer slides of the machine run continuously like a rivet header—making operation continuous, so that the machine, in a sense, "sets the pace" for the attendant.

A big advantage is gained, too, in having the main shaft, heading slide and hammer slides run continuously, doing away thereby with a starting and stopping clutch on the main shaft, and thus minimizing the attendant troubles of wear and clutch repair. Elimination of this clutch also makes higher speeds



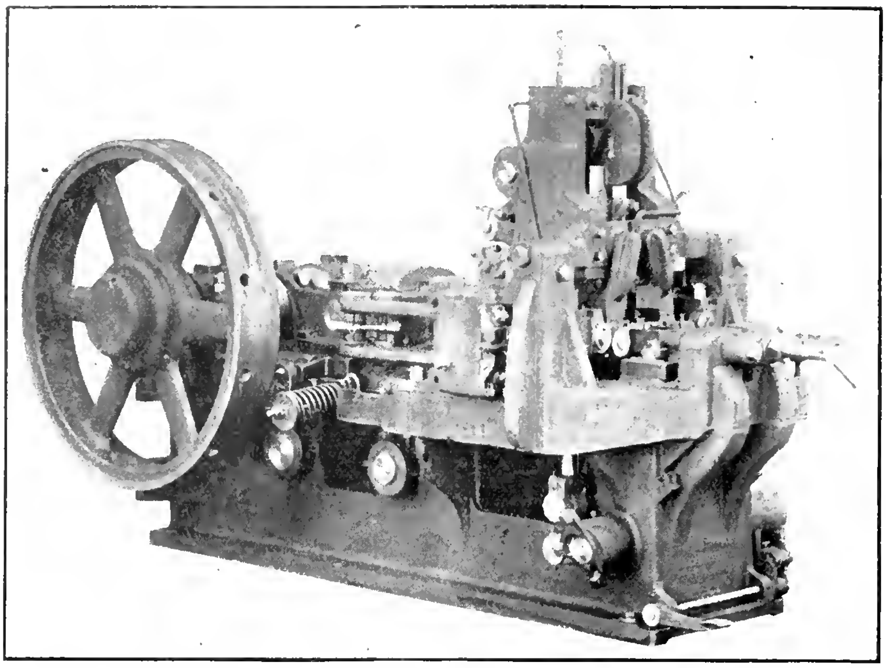
FRONT VIEW SHOWING SHEAR EQUIPMENT FOR MAKING BOLTS OFF THE ROD.

possible. A feature of the design is the ability to set or "time" the machine to make any quality of bolt wished—from

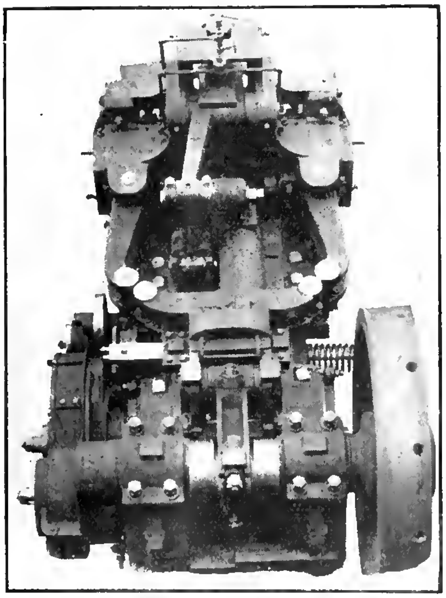
three to eight blows in one cycle or operation; and, with the machine thus set to deliver a predetermined number of blows, the quality of output and finish is necessarily uniform. The length of time, also, that the grips are open for feeding can be regulated to suit the needs or ability of the operator, according to the length or type of bolt being made. These changes are effected through a simple gear and cam construction.

The bed of the machine is of box type, of large proportions and heavily ribbed, inducing stiffness and rigidity as well as strength. The various working parts and details are designed correspondingly. This new hammer header of 1 in. size weighs in round numbers 13,000 pounds, and runs at 140 r.p.m. on its maximum work.

The rigid construction, combined with the mechanically operated grip, makes it practical to introduce a cut-off attach-



THE "NATIONAL" CONTINUOUS-MOTION SEMI-AUTOMATIC HAMMER BOLT HEADER.



REAR VIEW, SHOWING GENEROUS PROPORTIONS OF WORKING PARTS.

ment in the gripping dies, so that short bolts can be made directly off the rod. Short bolts ordinarily are hard to tong and to grip, and require cut-out dies that are expensive to make and maintain. With this shear or cut-off in the grip dies, however, short bolts are made with ease and facility, and four to six bolts can be made in one heat, depending somewhat, of course, upon the diameter and length of bolt made.

Another departure in this design is the lever construction for carrying the lower hammer. In previous designs the lower hammer was carried in a slide, similar to the side and top hammers, and the scale dropping off the bolt as it was being forged got on to this slide, and this, with the action of the water, caused much trouble because of the excessive wear. This wear caused disalignment of the lower hammer, and demanded constant attention. The lever construction eliminates this wear. The side and top hammer slides in this design are operated by bronze bushed links in place of cams and rolls.

The flywheel is of the "National" friction-slip construction, which fills the role of an automatic safety device in case cold stock or an excess of metal is gripped in the dies and obstructs the travel of the heading tool. An automatic relief is also provided on the gripping mechanism to protect the machine against damage, should the operator accidentally get stock or some foreign object in the grips, other than in the holding grooves, which would prevent the dies from closing, and the machine from completing its cycle.

The slides have been made extra long, and the shaft bearings are of large diameter and bronze bushed, the main shaft bearings being self-oiling. Practically all the bearings have a large oil pocket or cup oiler that is easily accessible; and these pockets, as well as all the oil holes, are provided with sliding or hinged covers to exclude entrance of any possible scale, dust or foreign substance that could induce friction.

This new hammer header is built in $\frac{3}{4}$ in., 1 in., and $1\frac{1}{2}$ in. capacities, for either belt or motor drive.

SHELLS AND GENERAL SUPPLIES FOR BRITAIN.

IF we might judge by the activities of our engineering and metal-working plant managements relative to the further development of the manufacture of shrapnel and high explosive shells in their every and complete feature, there is abundant evidence that if someone has not blundered, at least dissatisfaction over the paucity and scope of the orders placed exists. It has long since been proved that we can produce shells of first quality and in quantity ad lib, but, being now informed that our efforts lack all merit because only "empty" shells have been made, we naturally get up in arms to defend ourselves and at the same time give indication of both claiming and demanding the opportunity to produce shells with "fixed ammunition" and of earning the accruing merit by our handiwork.

Little compliment has been paid our engineering establishments during all these months of war in that no notice seems to have been taken in official circles of how they grasped and made a huge success of this shell forging and machining business. What was accomplished in this respect many months ago is as yet being only partly realized—much less appreciated officially, and little wonder is it that being fully aware of the call and necessity for "Shells, and Shells, Then More Shells," our leading metal-working plant managements have banded themselves together to "press their suit" without the official aid which was their right to expect, but their misfortune to lean too implicitly upon.

The concentration of effort indicated gives but concrete expression to a gradually developed necessity relative to shell manufacture in our Dominion. The steps already taken to establish and equip plants for the supply of "fixed ammunition" may be taken as a result of the initiative of our plant managements and their staffs. Arrangements are, we understand, now proceeding smoothly and satisfactorily with respect to the provision of fixed ammunition for the various sizes and types of shells being manufactured in Canada, and within the next two months it is expected that the various plants devoted to this feature will be in a position to cope with the output of what are known as "empty shells."

Some half dozen concerns are either equipping or are getting close to production stage relative to the manufacture of brass cartridge cases, and in the matter of the explosive charges, time fuses and detonators, the necessary arrangements have also been made. Much of course is expected from the coming interviews between Mr. Thomas—the accredited representative of Britain's Minister of Munitions, and our Shell Committee, and not the least important movement in the direction of fuller shell making opportunity is that which seeks to have our manufacturers' committee form a unit at the various conference sessions.

Further to the purchase of supplies for the British forces at home and on the European continent, it may be stated that a department for the purpose is now organized and operative in room 114, the Windsor Street Station Block, Montreal. Edward FitzGerald, assistant general purchasing agent of the C.P.R., has been deputed by Sir Thomas Shaughnessy to take charge of this special work. The supplies requirements will, of course, be both varied and numerous, and will in many instances reach to considerable proportions. Manufacturers of such commodities as are being used both on service and for consumption are invited to furnish particulars of their products, which should include prices, degrees of quality, quantities available, procurable and produceable on short notice. Shells, remounts and fodder do not come within the scope of the departmental activities.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Toronto, Ont., July 13, 1915. — War orders are the principal feature of interest in business circles and it is generally thought that large contracts will be placed in Canada for military equipment and supplies. The placing of the C.P.R. Purchasing Department at the service of the British Government will facilitate the purchase of supplies and also stimulate business in this direction. Manufacturers have now another organization to deal with in addition to the Commission appointed by the Canadian Government. The result of all this endeavor cannot but be of the greatest benefit to many Canadian manufacturers and a stimulus to a variety of industries. The foregoing is altogether apart from the shell industry, which of course is under the direction of the Shell Committee. In this regard, however, Russian and French shell orders have to be considered, as big business may eventually result. Contracts for Russian shells have of course already been placed, while an order for French shells is already on the tapis.

Taking everything into consideration, the outlook has during the last few weeks improved considerably, and indications point to a more extensive development in trade than was perhaps anticipated during the earlier stages of the war.

The Export Association of Canada which was recently organized and which

has its headquarters in Montreal, is endeavoring to enlist the support of the leading Toronto manufacturers. A conference was held here last week for this purpose. The Association was formed with a view to developing the export trade of Canada and to take as full advantage as possible of opportunities for trade that will arise during the period of reconstruction that will follow the war.

Steel Markets.

The shell industry continues to dominate the steel trade and production is being speeded up to meet the demand. Activity has spread to the steel foundries where blanks are being cast for the 4.5 shells, preparatory to forging, thus giving additional work for the forging plants. The demand for merchant bars is still light, and the outlook in the steel trade as regards ordinary business is improving and prices are very firm. Canadian mills have advanced prices on iron and steel bars to $2.20 f.o.b. Toronto.

The market for galvanized sheets is easier, but prices are practically the same as at the last advance; only a few makers of galvanized sheet products are offering material on account of the continued high price of spelter. Makers of tool steel are much concerned over the great scarcity of tungsten, one of the chief ingredients of high-speed steels. The price of this alloy has advanced considerably and tool steels are higher proportionately. The big demand for high-speed steel for tools and drills makes the situation more acute.

Further improvement in the steel trade is reported from United States centres. The export trade continues to develop, while the domestic business is also improving. Prices are very firm at the recent advances, and it is expected that present quotations will be maintained, if not further advanced.

Pig Iron.

There is no improvement in the pig iron situation as regards foundry requirements, although the blast furnaces at the steel plants are in active operation. Prices are unchanged.

Scrap Metals.

The market is firm for copper and brass scrap, and the demand continues good. Heavy melting steel is more active and prices are firmer. Scrap zinc and lead are quiet but unchanged.

Machine Tools.

The situation in the machine tool trade is practically the same as last week, fewer inquiries have been received ed by local dealers, but they are busy filling orders already placed. The absence of contracts for shells has been satisfactorily explained and further orders will be placed as soon as the firms making cartridge cases, etc., can meet the demand so that fixed ammunition only will be shipped to England. Interest will be centred on 18 pdr. and 4.5 high-explosive shells when the activity is renewed, and there will be a good demand for the necessary machines and tooling fixtures. Many makers of machine tools are booked up for months ahead, and prices are advancing.

Supplies.

Business continues to be very satisfactory with an increasing demand in connection with making shells. Chucks, collapsible taps, twist drills, reamers, belting, cutting compound, etc., are all in good demand. The only price change of importance to note this week is in iron pipe fittings, which have advanced. The new discounts are as follows: Canadian malleable, 25 per cent. for A, and 35 per cent. for B and C classes; cast iron, 60 per cent.; malleable bushings, 60 per cent., and standard bushings, 60 per cent.

CANADIAN GOVERNMENT PURCHASING COMMISSION.

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George Gault, Winnipeg; Henry Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Metals.

There is nothing of particular interest to note in the metal market this week. Prices are at the same level and generally steady. The situation locally continues undisturbed and the demand for metals for munitions is unabated. Ordinary business appears to have improved, but is hardly up to the normal. A scarcity of spelter and aluminum exists with no expectation of any relief for some time. The Imperial Government has placed an embargo on the exportation from Great Britain of all metals necessary in the manufacture of munitions.

Tin.—The market weakened slightly at the end of last week but has recovered and is now firmer and quiet. The present consumption of tin is very large and will continue to be so for some time. Quotations are unchanged at 46c per pound.

Copper.—The market is quiet and the tone is inclined to be easier. The copper situation, however, is a strong one and with consumption on the increase any change in price will probably be upwards. Local quotations are unchanged at 21½c per pound.

Spelter.—The market is steady but the general situation has not improved. There is good business being done in all positions up to the end of the year and some of the export orders go into the first quarter of next year. Quotations are nominal at 28c per pound.

Lead.—The market is dull and easier but quotations are unchanged. The lead situation is improving gradually and an upward movement is expected in some qparters. Lead is quoted locally at 7½c per pound.

Antimony.—The market is quiet but the demand is somewhat better, although prices have an easier tendency. Quotations are nominal at 40c per pound.

Aluminum.—The scarcity of supplies of aluminum is still felt, and prices are being maintained at the present unusually high level. Quotations are nominal at 40c per pound.

St. John, N.B., July 10, 1915.—Friends in the manufacturing trade throughout the Eastern Provinces will join with many others in extending congratulations to Hon. John E. Wilson, M.P.P., upon his appointment to the important position of deputy receiver-general and manager of the Government Savings Bank in this city. The appointment was recently announced. Hon. Mr. Wilson is president of the firm of J. E. Wilson, Ltd., iron founders and sheet metal workers. He has been prominent in local business and political circles for many years. Hon. Mr. Wilson was for some time a member of the old common council, and in 1908 was elected to a seat in the Legislature at Fredericton, being re-elected in 1912. He was then made a member of the cabinet without portfolio, and was also chosen president of the legislative council. He will now quit public life and retire to the quieter precincts of the civil service in an office well deserved after his years of service to the Conservative party.

The big spandril arch bridge, the largest in the world, across the Reversing Falls, St. John, N.B., will soon be thrown open to the public. The flooring was finished this week by A. R. C. Clark & Son, and the approaches will be finished in the near future by J. McVey & Son. The new bridge is of steel and is a magnificent and inspiring structure.

The contract for the substructure and approaches of the new highway bridge over the Petitcodiac river at Moncton, N. B., has been awarded to Engineers and Contractors, Ltd., a Nova Scotia concern. L. A. Keith is at present acting as their agent in this city. The president of the firm is E. R. Reid of Annapolis, N.S., while his partner is E. M.

Archibald, a graduate in engineering, from McGill University, and also residing in the Annapolis valley. Work has been started on the bridge, and will be rushed to completion as rapidly as the circumstances warrant.

The Maritime Dredging & Construction Co. is setting forms in place along the top of No. 1 extension, West St. John. Concrete will later be poured into the wall until it is elevated to a level with the new docks. This wall, known as the "Connolly Dock," is 300 feet in length and about six feet below the required height.

Miles E. Agar, hardware manufacturer, of St. John, and Matthew Lodge, of Moncton, N.B., have left for England to confer with the directors of the Maritime Oil Fields, Ltd., respecting the extension of a lease of the oil and gas privileges of the New Brunswick Petroleum Co., now held by the former concern. The lease is just expiring, and Messrs. Agar and Lodge plan to consult about its extension and enlargement.

TRADE WITH RUSSIA PROSPECTS.

GREAT possibilities for Canadian trade with Russia are revealed in the first report sent by Special Trade Commissioner Conrad F. Just to the Department of Trade and Commerce.

Mr. Just has concluded his investigations in the Petrograd district, and is now working south and east. He has had a number of conferences with members of the Russian Government and with leading bankers, having had considerable assistance from the British Commercial Attache and British Consul at Petrograd. He points out that at the outbreak of the war, Germany, after 25 years of effort, had to her credit 52 per cent. of the import trade of Russia. Since the war, the conventional tariff rates have been withdrawn, the general tariff increased by 10 per cent., and a surtax of 100 per cent. imposed against Germany and Austria. The war has not devastated any true Russian areas, but districts which constituted the base of the German economic penetration of Russia.

Russia, says Mr. Just, has great powers of recuperation, is internally rich and prosperous, and affords "great opportunities for industrial enterprise for which the consuming power is at hand." These factors, the report states, should make Russia a great market, "and if the conditions be rightly studied and understood, Canadian manufacturing industries, by the nature of the products, which are adapted in so many instances to the requirements of a developing country like Russia, may reasonably expect to participate in the trade with that market."

Agriculture is the occupation of 85 per cent. of the Russian people, and the manufacturing industry furnishes an insignificant output in relation to the country's needs.

Canadian Exports Confused.

Mr. Just says that Canadian machinery exports to Russia have been confounded with those from the United States. He advises Canadian traders to organize on the basis of a close study of the Russian requirements and to keep in touch with the consumer by means of local agents, who play a very prominent part in connection with the foreign trade of Russia. Firms seeking trade with Russia should enter the market in groups or syndicates, this being possible when the products of such firms do not compete, but are complementary to each other. It is also desirable to have assembling shops in Russia, particularly for machinery, thus saving on Customs duties and permitting tendering on Government works. A start should be made in Petrograd, where the Russian fashions are set.

"The successful participation of Canada in the contracts of the Russian Government for munitions of war, railway rolling stock, and it is believed for locomotives and other materials, has created lively interest in Russian official banking and commercial circles," says the report, "and should prove an excellent advertisement of the capabilities of the Canadian industrial system."

Canadian leather supplies, it is added, would be snapped up at high prices. "A pair of Russian army boots has a life of two months."

SHELL MANUFACTURERS IN CONFERENCE.

FULL information with regard to the shell-making capacity of Canadian industries will be placed before the British Government's representative, Mr. Thomas, who is expected to reach Ottawa some day this week. With this object in view, a number of leading manufacturers have held a meeting here in conference with members of the Shell Committee. There were present T. A. Russell, of the Russell Motor Car Co.; Wm. Inglis and Campbell Rives, of the John Inglis Co.; Mr. Findlay, of the Massey-Harris Co.; Mr. Gurney and Mr. Tinson, of the Crocker Wheel Co.; Alex. Goldie, of Goldie and McCullough; Col. Frederick Nicholls, of the Canadian Allis-Chalmers Co.; Robert Hobson, of the Steel Company of Canada; Mr. Niven, of the Otis Fensom Co.; Col. J. B. Miller, of the Polson Iron Works, Gen. Bertram and other members of the Shell Committee.

It was explained by Col. Nicholls that the meeting had been called for the purpose of considering what more could be done to relieve the ammunition shortage in view of the approaching visit of Mr. Thomas. Large sums of money would be spent if necessary on equipment for turning out completed shells on a large scale.

It was sugested by Mr. Findlay that, through the proper medium, the Shell Committee, a delegation of manufacturers should meet Mr. Thomas and discuss the situation with him. He thought that if fixed ammunition is required, assembling plants should be established on a large scale, so that larger orders could be undertaken.

Mr. Nicholls stated that they had received proposals to take foreign orders, but preferred to wait for orders from the War Office through the Shell Committee. Larger orders would enable the manufacturers to invest capital in additional equipment without the danger of the work being insufficient to warrant the outlay. He suggested that the Government or the Shell Committee should establish a large assembling plant or, if not, the manufacturers were prepared to do it.

It was proposed by Mr. Russell that a statement be prepared for Mr. Thomas, showing the number of firms ready to undertake shell manufacture on a large scale, with details as to which of these firms would undertake the machining of shells, the manufacture of cartridge cases, of primers, and so on.

General Bertram assured the meeting that the War Office was prepared to place further and larger orders with the shell committee as soon as it could be shown that the work could be done. General Pease had assured him that Canada could secure all the orders necessary as soon as the manufacture of cartridge cases and the loading capacity warranted the placing of further orders. General Bertram explained the difficulties that had arisen in connection with the manufacture of cartridge cases and the loading.

The meeting ended after a full and exhaustive discussion and with the suggestion that the manufacturers co-operate with the Shell Committee in conferring with Mr. Thomas.

CANADIAN MINERAL PRODUCTS FOR BRITAIN.

THROUGH the medium of the High Commissioner's Office, trial orders have been given by the British authorities for certain Canadian mineral products found in Ontario and Quebec, and those who grumble about Canada's share of war contracts have no conception of the large orders already passed, at least so we are given to understand. The Imperial Government is adopting the policy

of giving the Dominion every possible chance.

Col. Pelletier, agent-general for Quebec, is also supplying certain minerals from Quebec to the French analysts, who hold out great hopes of utilizing the same for war munitions.

BRITISH OPENING FOR SAW-MILL MACHINERY.

MANUFACTURERS of saw-mill and woodworking machinery may be interested in Trade Inquiry No. 831, which has been received from Harrison Watson, Trade Commissioner at London, notifying the Department of Trade and Commerce, Ottawa, of the name of a firm, who are large manufacturers of saw-mill and woodworking machinery. As their own plant is heavily engaged in Government work, and as they are receiving inquiries from all parts of the world which they cannot deal with themselves, they are prepared to receive complete information from any Canadian manufacturers of saw-mill and woodworking machinery, to enable them to negotiate for orders without being obliged to refer any further to Canada. They wish to be placed in the same position as that in which the manufacturer would put his traveller or agent. Canadian manufacturers, wishing to avail themselves of such an opportunity may be supplied with the name of the firm by applying to the Department of Trade and Commerce, Ottawa. (Refer File No. 810).

MARKET FOR WIRE RODS IN BRITAIN.

CONSIDERABLE quantities of wire rods have hitherto been sent to the United Kingdom from Germany, and as supplies have now ceased, consumers are experiencing much difficulty in obtaining adequate supplies from home sources. Another factor which is handicapping producers is the difficulty of securing labor, as so many skilled men have enlisted in the army.

If Canadian manufacturers are able to export these rods, the information ascertainable covering the following particulars may be of service. The rods required should be of soft and hard steel and in what is known to the trade as 4, 5 and 6 gauge. The soft steel rods should have 0.10 per cent. carbon, and the hard steel rods 0.40, 0.50 and 0.60 per cent. carbon. The soft rods are intended to be drawn into wire for the making of such articles as boot rivets and wire mattresses, while wire obtained from the hard rods is used among other purposes for card clothing and also for wire rope making.

Maxville, Ont.—The Borden Milk Co. contemplate the erection of a condensed milk factory here.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Smith's Falls, Ont.—The Frost & Wood Co. have received an order for making shells.

Brampton, Ont.—It is reported that the Pease Foundry Co., have received an order for shells.

Montreal, Que.—W. A. Dean, of Toronto, will establish a plant for building flying machines near Montreal.

Corbyville, Ont.—The H. Corby Distillery Co. are in the market for a motor-driven pump and an air compressor.

Gananoque, Ont.—The Steel Co. of Canada, Ltd., will probably build an extension to their plant at this place. Head office is at Hamilton, Ont.

Chatham, N.B.—The Maritime Foundry Co., are erecting a factory to make shells. The building will be 80 x 40 feet and will cost about $40,000.

Toronto, Ont.—The Board of Control has instructed Works Commissioner Harris to report on the cost and advisability of building car shops in this city.

Paris, Ont.—The Bell Foundry Co. of St. George have installed a complete machinery equipment for the manufacture of shells, and they commenced operations this week on a large order.

Sherbrooke, Que.—The City Council has decided to proceed with the erection of the new gas plant at an estimated cost of $75,000. Tenders for one gas holder will be accepted in the meantime.

Smith's Falls, Ont. — The Frost & Wood Co. have received an order for shells to the extent of $100,000. The company will install additional machinery. The initial outlay for the equipment will be $25,000.

Toronto, Ont.—The Chevrolet Motor Co., of Canada, Ltd., which has recently been incorporated with a capital of $50,000 will establish a plant here. W. C. Durant, president of the Chevrolet Motor Co., New York City, is interested in the Canadian concern.

Electrical

Smithville, Ont.—The installation of an electric lighting system is under consideration.

Kincardine, Ont.—The council will purchase a number of 60-watt lamps.

Orillia, Ont. — The Orillia Water, Light and Power Commission will extend their transmission lines to Longford.

Toronto, Ont.—The Parks Committee has decided to put cluster lights on University avenue, so that men who have to work by day will get a chance to drill in the open at night. This work will cost $12,000.

Orillia, Ont.—The Orillia Power Commission will probably be able to supply Longford with electric current after all, an alternate route having been secured through Orillia township to Washago and thence to the Standard Chemical Co. works at Longford. John McRae of Ottawa, is consulting engineer for the commission.

Municipal

Burlington, Ont.—The town will raise $50,000 for the proposed sewage system.

Hamilton, Ont.—Fire Chief Ten Eyck has recommended the installation of several fire alarm boxes.

Sackville, N.B.—The Town Council are contemplating additions to the waterworks plant. A pump may be required.

Pembroke, Ont.—The Town Council are considering the purchase of a combination hose wagon and chemical engine. Clerk, A. J. Fortier.

Toronto, Ont.—The Board of Control has decided to proceed with the construction of the new street railway tracks on Bloor street west.

Montreal, Que.—The Controllers reported to the council that a by-law should be adopted without delay to vote a sum of $1,000,000 for needed improvements to the waterworks. In addition to this sum an additional amount of $74,000 is required to expropriate land for waterworks extension purposes, land not ceded to the city.

Hamilton, Ont.—The construction of a reservoir with a capacity of 17,500,000 gallons, and provision for eventually increasing the maximum capacity to 50,000,000 gallons, is recommended by Kerry & Chase, of Toronto, the engineers who have been investigating the possibilities of economizing in the operation of the water works system.

Sarnia, Ont.—The Sarnia Gas & Electric Light Co. has received from the City Council an offer for its entire electrical plant, lines and properties, the sum offered by the corporation being $155,000, which represents the figure advised by Engineer Jeffries, of the Hydro Commission, who some time ago made an estimate of the whole situation. If the company will accept this figure the council will have a by-law prepared to submit the question to the ratepayers.

Mimico, Ont.—The New Toronto Council have definitely decided to link up with Mimico and construct a sewage system and disposal plant which will accommodate the needs of both municipalities. The disposal plant will be built in Mimico, but the council refuse as yet to disclose its exact location. The pump house, a portion of the new works will, however, be constructed at the lower end of Superior Avenue. The cost of the new system will amount to about $50,000, according to the estimates of the engineers.

General Industrial

Peterborough, Ont.—Fire has destroyed the brick plant of Curtis Bros.

Montreal, Que.—The A. Racine Co. are building a carriage factory here.

Martintown, Ont.—A. E. Clingen's sawmill has been destroyed by fire. Loss, $7,000, partially covered by insurance.

Fort William, Ont.—The Ogilvie Milling Co., are considering making an addition to their elevator here which will increase the capacity by 750,000 bushels.

Preston, Ont.—The Hurlbut Shoe Co., which was given a loan of $25,000 from the town, has plans drawn for a three-storey building on Queen street, near the present factory.

Lethbridge, Alta.—It is possible that the Taylor Milling Co. and the Lake of the Woods Co. may erect elevators at Foremost. There are already elevators of the National Grain Co., and the Farmers' Co-Operative Elevator Co. at this point.

Tenders

Ottawa, Ont.—Tenders on the supply of transformers, switches, and equipment will be received until August 3 by the chairman of the Waterworks Commission. Plans and specifications with the city engineer, R. L. Haycock.

Ottawa, Ont.—Tenders will be received until August 3 for high-lift pumps and motors for the Lemieux Island pumping station. Plans and specifications may be obtained from the consulting engineer, S. B. MacRae, Ottawa.

Oakville, Ont.—Tenders will be received by the chairman of the Oakville Water and Light Commission until Monday, July 26, 1915, for furnishing and installing one electrically-operated turbine pump of 600 Imperial gallons capacity against a head of 300 feet. Specifications may be seen at the office of the Commissioners, Oakville, or at the office of Chipman & Power, engineers, Mail Building, Toronto.

Building Notes

Toronto, Ont.—J. W. Siddall, architect has taken out a permit for a factory to cost $7,000 at 71 Sterling road.

Toronto, Ont.—H. T. LePage has taken out a permit for the erection of a concrete block factory on Dundas street to cost $10,000.

Barrie, Ont.—The general contract for the new Carnegie Library has been let to the Ball Planing Mill Co., of this town. Chapman & McGiffin, of Toronto, are the architects.

Toronto, Ont.—The city architect has issued permits for additions to two public schools, the Searth road school to cost $22,000, and the St. Clair avenue school to cost $27,300.

Toronto, Ont.—The Borthwick Baking Co. have been granted a permit by the City Architect's Department for the erection of a two-storey addition to their factory on Davies avenue. The work will cost $14,000.

Port Colborne, Ont. — The School Board has adopted the plans for the proposed new school on Steele street which is estimated to cost $35,000. Architect Porter of Niagara Falls, Ont., will prepare specifications, etc.

Vancouver, B.C. — The Merchants Bank has awarded a contract for the erection of a headquarters building in this city, to cost $175,000. It will be of four stories, and will be located at the corner of Pender and Granville streets.

Vancouver, B.C.—Work will start immediately on a three-storey building for the Merchants Bank at Granville and Pender streets, which will cost when completed approximately $175,000. The plans have been drawn up by Somerville & Putnam, architects, of this city.

Railways-Bridges

Vanconver, B.C.—It is announced that the main line of the Canadian Northern Pacific Railway will be ready for operation by September.

Toronto, Ont.—The York County Council has granted a sum of $2,000 towards the construction of Jersey Bridge at North Gwillimburg.

Toronto, Ont.—The York County Council has under consideration the construction of a bridge at Locust Hill, the estimated cost being $20,000.

St. Thomas, Ont.—The London & Port Stanley Railway Commission will in a few days commence the erection of a new station and office building, on Talbot street.

Calgary, Alta.—The City Council are considering the question of extending the street railway tracks to the Sarcee military camp. The citizens are in favor of the extension.

Brantford, Ont.—The electrification of the Lake Erie & Northern Ry. from Port Dover to this place will be proceeded with during the summer. Rolling stock will be purchased.

Calgary, Alta.—George H. Webster has been given the contract to build the Spirit Lake-Grand Prairie branch of the Edmonton Dunvegan and British Columbia Railway, now under construction by J. D. McArthur.

London, Ont.—The London & Port Stanley Railway Commission have closed the deal for the Gootson property on Ottaway Avenue, for car shops. Possession will be given at once, and the work of erecting the buildings will commence shortly.

Arnprior, Ont.—The new bridge to be erected over the Madawaska river at Burnstown by the county council and township council of McNab is to cost in the neighborhood of $26,700. It will be of cement and concrete, and its length will be over 300 feet.

Brantford, Ont.—The offer by the city of the sale of the Grand Valley Railway line from Paris to Galt for $30,000 and electrification of the L. E. & N. Railway, from Port Dover to Brantford has not been accepted by M. H. Todd, General Manager of the Lake Eric. He offered $26,000, the city to retain the Galt powerhouse. He will submit the city's offer to the C. P. R. board, but will not recommend it.

Chatham, Ont.—The Hydro-Electric Power Commission of Ontario is negotiating with the C. N. R. for the purchase of the Chatham, Wallaceburg and Lake Erie Railway, which runs from Erie Beach on the south to Wallaceburg on the north. If purchased, the line will be made the nucleus for a hydro radial system in this part of the province, and the road will be extended to Sarnia through Petrolea and other places about to instal Niagara power.

Brantford, Ont.—The city's offer to the Lake Erie & Northern Railway, through the C. P. R., to sell the Grand Valley Railway from Paris to Galt, has been accepted. The price, it is understood, was $26,000. This means that the Lake Erie & Northern Railway will be electrified from Brantford to Port Dover. This gives electrical railway communication with Lake Erie. Orders for electrifying material will be placed at once and work will be rushed.

Lake Superior Division, G. T. P.—The Lake Superior division of the G. T. P. was taken over by the Government on July 1 under lease, and will be operated as part of the National Transcontinental Railway. The rental as announced previously is $600,000. The Grand Trunk Pacific Railway system now stops at Winnipeg. Hitherto it extended virtually to Fort William via the Lake Superior division, the intervening National Transcontinental link between Graham and Winnipeg having been used by the G. T. P. under a lease from the Government. All the lines east of Winnipeg will now be operated by the Government, the G. T. P. eastbound traffic at Winnipeg being taken over by the Transcontinental.

New Incorporations

The Bull Tractor Co. has been incorporated at Ottawa with a capital of $25,000 to manufacture gas tractors, gas engines, motor trucks, motor cars, etc., at Winnipeg, Man. Incorporators: Garnet Coulter and Percy John Procter, of Winnipeg, Man.

The Nitrogen Products, Ltd., has been incorporated at Ottawa with a capital of $300,000 to manufacture by electrical or other method atmospheric nitrogen, nitric acid and nitrates of all kinds at Toronto, Ont. Incorporators: William Bourne, and William John Lockwood McKay, of Toronto.

Principles of Design and Lubrication of Bearings

By Frank Foster, M.Sc.

The subject matter of the accompanying article is such as will prove both interesting and instructive to machinery designers and operators. Not a few plain definite statements are made relative to bearing metals and to the means employed to secure efficient lubrication of a journal when carrying its normal load, all of which give food for thought and stimulate a desire to more fully grasp the essentials of these important engineering problems.

DESIGN AND LUBRICATION OF BEARINGS.*

By Frank Foster, M.Sc.

BEARINGS are almost entirely designed according to various empirical rules. Certain general principles based on experimental evidence and reasoning can profitably be associated with these empirical rules, and in some instances current practice may thus be modified with advantage.

Engine lubrication consists in separating two metallic surfaces by means of a film of fluid, usually oil. With perfect lubrication the metallic surfaces do not touch at all, and no wear takes place. Usually, even with the best of lubrication, metallic contact occurs on starting up and sometimes continuously on high spots until these are rubbed down. To avoid spot contract, careful bedding is necessary, especially on large bearings. With imperfect lubrication, such as is usually the result with drip feeds, the oil film is thin and liable to be broken, permitting intermittent or local metallic contact and wear. The laws governing such restricted lubrication are available and differ from those for perfect lubrication. Most empirical bearing rules date back to the days of drip and other forms of imperfect lubrication. Hence it is often possible to revise these old rules, but in doing so the chances of damage are more serious if the full oil supply fails for any reason. For this reason some authorities urge that bearing design should be based on imperfect lubrication, but this is not accepted by designers of turbines and other modern high-speed machinery.

Bearing Load.

The load a bearing can carry when working normally is a matter of viscous hydraulics and not of bearing metals. Bearing metals are important from reasons of manufacture or repair, and in case the lubrication becomes faulty. Lubrication being a matter of hydraulics, correct conceptions of bearing phenomena can best be obtained by thinking of oil as flowing through the extremely shallow, but relatively wide channel between the two bearing surfaces. Looked at from this point of view certain conditions are evident.

1—Oil should be supplied to points at which there is no bearing pressure.

2.—Escape of oil should be prevented except at the proper delivery edge.

3.—The relationships between bearing pressure, speed of flow, thickness of oil film, and viscosity of oil will depend largely on the rate at which the oil is supplied to, and can escape from, the bearing.

4.—The oil film is under the pressure due to the load, and hence the oil must be drawn or forced into the bearing by some means or other.

5.—The physical properties of the bearing metal are relatively unimportant during normal working.

The most important general principle is that stated in (4). With very rare exceptions bearings are their own pumps. The one notable exception is the footstep bearing of the vertical Curtis steam turbine, where the rotor floats on liquid supplied under heavy pressure. In all usual cases of so-called "forced lubrication" the pressure merely ensures that the oil reaches the supply inlet of the bearing. The bearing itself pumps or draws the oil from the supply pressure of a few pounds per square inch to several hundreds.

Bearing Pumping Action.

The natural pumping action of a bearing may be either (or both) of the following kinds:—

1.—The oil adheres to the moving surface, such as the shaft journal, and is dragged into the narrow channel between the (so-called) rubbing surfaces.

2.—The oil is sucked into a portion of the oil channel which is under negative pressure, and upon the reversal of the load is brought under pressure.

Regarding the first of these natural pumping actions, the following considerations apply:—

(a)—The inlet edge of the bearing must be bevelled so as to facilitate intake of oil and not to scrape it off the journal.

(b)—The load the bearing will carry is limited by the outflow or escape of oil previous to reaching the natural delivery edge. This outflow increases with undue clearance, short necks, badly placed oil grooves, low viscosity of oil, and high bearing temperature (this reduces the viscosity), and is very detrimental to good lubrication.

Oil grooves are ill understood and often placed so as to be worse than useless. They have only two proper functions:—To supply oil to suitable local inlets of the bearing and to form closed reservoirs or advanced supply depots, from which more advanced portions of the bearing can be lubricated. All oil grooves should be well chamfered at the delivery, or outflow, edge. This is most important.

Typical Bearing Examples.

A few typical bearing examples will serve to illustrate some of the above points

1.—For a rotating journal under steady load, such as dynamo journals, the oil should be fed to the top or sides where there is no pressure; ring lubrication, therefore, gives good results.

2.—For an oscillating journal under steady pressure, such as the crosshead pin of some single-acting engines, oil should be supplied at the sides, where there is no pressure. Part of the oil dragged in by the journal adheres to the bearing, which passes it on again to the journal higher up on the return oscillation. A closed oil groove (with chamfered edges) parallel to the axis of the journal, and some little distance in from the inlet edge, acts as an advanced supply depot.

3.—Is similar to 2, but with the load alternating in direction; as in the usual crosshead pin. In this case the pin itself pulses fore and aft and acts as a pump plunger. The oil inlet in this case may profitably be in the line of pressure, as it has to feed rapidly during suction; but side feed to the neutral regions is good in many instances.

4.—For a reciprocating bearing under fairly steady pressure, as a crosshead slipper and slide, the inlet to the oil channel between the rubbing surfaces

*From a paper on "Essential Principles of Engine Design" read before the Manchester Association of Engineers.

should be well chamfered, and drip, oil groove, or other feed to intermediate parts of the slide is desirable.

It will be noticed that since the oil is being squeezed out of a bearing, the thickness of the film must decrease from the inlet until near the outlet. In fact, without this, lubrication is very imperfect; and for this reason parallel rubbing surfaces, such as collar thrust bearings, are very difficult to lubricate. By adjusting these rubbing surfaces to give a succession of tapering oil channels with suitable feeding arrangements, this difficulty can be overcome and loads greatly increased without risk. This principle has, in fact, been successfully applied in practice. In the case of ordinary shaft bearings the wedge, or taper formation of the oil channel, is the result of the journal settling itself eccentrically in the bearing.

Professor Alexander deduces from theoretical considerations that the clearances between similar bearing surfaces for machines of the same form and duty should vary as the square root of the journal diameter, or equivalent linear dimension. This is contrary to usual shop rules, but it is interesting to note that practically the same law was worked out from experience and general considerations by the author more than a year ago. This is shown by Table I., showing allowances on diameter in thousandths of an inch for copious lubrication. With drip feeds smaller allowances are desirable.

Table I.—Crankshaft and Crank Pin Journal Allowances.

Diameter, inches	25	20	15	12	10	8	5	3	2
Proposed allowance	12	11	10	9	8	7	6	5	4
Theoretical allowance	12.6	11.3	9.8	8.75	8	7.15	5.65	4.4	3.6

The usual principle adopted in engine design is to allow certain pressures on the various journals. Tables II. and III. give usual practice, pressures being calculated on total piston load without modification for angularity of rod and inertia.

Table II.—Horizontal Engine Bearing

Bearing.	Lbs. per sq. in.
Crosshead pins	1,200—1,300
Crank pins	800— 950
Crankshaft journals (steam load)	100— 150
Crankshaft journals (combined loads)	150— 200
Second motion bearings	100— 200
Crossbead slides	40— 50
Intermediate piston rod slides	20— 40

Inertia should be allowed for in special cases. Journal speeds are rarely taken into account, but there is at present a tendency to do so, especially in Germany. The influence of speed is complex. In many cases it improves the load which can be carried, but it also increases the heat developed per second, and where the pressures are not such as to endanger the oil film, may limit the safe load on the bearing by the tendency towards overheating. For this a rule of the form—

Pressure per square inch $\times$ journal speed in feet per second $=$ Constant

is used, but the "constant" varies so widely that its value in the present state of knowledge is limited.

Table III.—Usual Bearing Pressure for Vertical High-Speed Engines.

Bearing.	Lbs. per sq. in.
Main bearings	200—300
Crank pins	400—550
Crosshead pins	1,000—1,200
Crosshead slippers	40—50
Eccentric straps	60—70

Bearing Metal Choice.

The choice of a bearing metal is determined probably more by abnormal working conditions than by normal. When working normally with a plentiful supply of oil the bearing and its journal are not in metallic contact, and the composition of the bearing metal is of practically no moment provided that the steps are sufficiently strong and rigid. On the other hand, the bearing metal becames an important factor in case of failure of the oil supply or overloading of the bearing. Metallic contact then takes place, and considerations of seizing, undue heating and melting out arise. The composition of the bearing metal has also an important bearing on questions of manufacture and repair, especially in the case of large bearings which call for extensive scraping and bedding. The extensive use of white metals is due to their merits under these heads rather than to any particular merits they may have under normal working conditions. In connection with white metals one important point may be mentioned. It is very important to secure close metallic contact between the white metal and the shell of the step so that disintegration is avoided and the heat necessarily generated in the bearing conducted away and radiated without undue temperature rise at the oil film.

HIGH EXPLOSIVE SHELL MANUFACTURE

At a time when high explosive shells are in such enormous demand, we feel says "Herbert's Monthly" that our readers would appreciate an outline of the operation methods which can be employed in making 18-pounder shell bodies, the size which is required in the greatest numbers. The design of these shells is such that the machining is not difficult, and rough material can be used in the form of pieces cut from the bar, which is therefore obtainable by anyone.

The chamber for the explosive being drilled from the solid, either a lathe or drilling machine can be employed for this operation. Further, the outside turning can either be done on engine lathes, or on turret lathes with a roller steady box-tool. It will thus be realised that the number of permutations of the operations by which the machining may be done is very great. We will however, confine ourselves to a description of three typical processes, any of which can be modified in detail according to the plant available. In all cases the material is best used in the form of blanks cut-off from bar, and consequently smaller lathes can be utilised than if the bar had to pass through the spindle.

The blanks can be cut-off on various types of machines, but it is worthy of note that the general practice is to partially cut-off a series of blanks from the bar in order that they can all be inspected and stamped at one time. They can then be broken off and used as required.

If the blanks were completely cut-off, the inspector would have to spend the whole of his time at the cutting-off machine to stamp each blank as it dropped off.

First Method

The first method employs a combination of engine, capstan, and turret lathes. The blanks are first centred at both ends on a centring machine, or sensitive drilling machine, and are then transferred to an engine lathe, where the outside diameter is rough and finish turned as far as the band groove, and the nose profile turned or formed. On being transferred to the next engine lathe, the remainder of the outside diameter is turned, and the large end faced to a definite length.

No. 1 hexagon turret lathes are employed for the next operation, where the shells are chucked nose end outwards, the hole drilled, bored, recessed and tapped. After this operation the shell is adjusted to a definite weight by facing off the closed end, after which it is transferred to a No. 4 capstan lathe, where the chamber for the base plug is bored and chased. The base plug is now inserted, cemented and riveted.

The succeeding operation on the bodies consists of forming the grooves for the copper band, which includes the machining of the waved ribs, and this is done on No. 4 capstan lathes. The chuck carrying the shell is fitted with a double sided former cam, and in the groove a peg fits which actuates the oscillating tool holder carrying the form tool. At the same operation the closed end of the shell is finish-faced. The copper band is next pressed on, and machined on any type of simple lathe with a form tool, a plug being fitted into the open end of the shell.

With regard to the manufacture of the base plugs themselves: these are

made from steel stampings, with either a hexagon or square head stamped on to enable them to be screwed home. A hexagon head is better than a square head, as it enables the stamping to be held in a three-jaw chuck. The actual machining is done on a screw-cutting lathe, fitted with a square turret.

In order to facilitate riveting, a groove is cut near the outside on the unmachined side, so that the edge can easily be turned over.

Second Method

By this method practically the whole of the work is done on capstan and turret lathes. The blanks are chucked in a No. 1 hexagon turret lathe, where they are drilled, bored, recessed, tapped, turned as far as the band groove with a roller steady box-tool, and the nose formed.

At the next operation they are held in a chuck on an engine lathe, the remainder of the outside diameter turned, and the closed end faced to length.

They are then adjusted for weight as previously described, and afterwards the chamber for the base plug is bored and chased on a No. 4 capstan lathe, the succeeding operations being exactly as described in the first method.

Third Method.

This method utilizes a combination of drilling machines, engine lathes and capstan lathes. The blanks are first roughly drilled on a drilling machine, and are afterwards transferred to an engine lathe, where the outside is rough and finish-turned true from the drilled hole, and one end faced. They are then chucked on a No. 1 hexagon turret lathe, where the bore is finished, recessed and tapped, and the nose formed.

The shells are next adjusted for weight, bored for the base plug, and the succeeding operations are the same as the two previous methods.

Use of Automatic Turning Machines.

In the three methods above described, automatic turning machines are not included, but a number of the operations are being performed on this type of machine, with a consequent low rate of labour cost. Both No. 4 and No. 6 automatic turning machines are equally suitable, and the two alternative tool arrangements usually employed are as follows:—

In one case the rough blanks are chucked, and at one setting the hole is drilled and bored, the outside turned as far as the band groove, and the nose formed. In this case, the recessing and tapping of the nose has to be done subsequently as well as the machining of the base plug end and the band groove.

In the second method, the blanks are delivered to the machine with the hole roughly drilled, and the outside rough turned true with the hole. On the automatic turning machine they are then finish bored, finish turned, and the nose formed. In this case also, the thread at the nose end is recessed and tapped subsequently, and the machining of the base plug end done on other machines.

The specifically mentioned machine tools in this article refer, we presume, to the classification adopted by the makers, Alfred Herbert, Ltd., Coventy, England.

BRASS MELTING QUERY.

HAVING seen a few copies of your publication and noticing some questions and answers in same, I am taking the privilege of asking a question re some metal I am having trouble with. This metal (brass) has been put through a fireclay-lined gas retort with a view to obtaining it in large quantities, the composition being: copper 85, lead 10, tin 5. We lose a lot of metal due to its sticking to the lining and also to its coming out mixed with same. Could you suggest a way of getting this metal free of slag or lining? We have put it through crucibles, and some of the metal goes to the bottom all right; still the top of the crucible has a very tough and spongy material, hard to make an opening into to get our melted metal free to pour, and leaving a lot of it still in this mixture. We have a great quantity of this material on hand, and are anxious to get the trouble solved.

We have tried charcoal as a flux, also salt, but get no better results, and were thinking of smelting it same as iron, having rolled a shell 6 ft. long by 30 in., and having brick-lined it. Would you advise this process, and could you give us a dimensioned sketch for its development? We are supplying air by electric fan, and, for air passage around shell, make a recess in the brick lining, so as to not be bothered cleaning out air holes in a circular pipe. These few points are mentioned so that they can be enlarged upon.—Subscriber.

SELECTIVE ASSEMBLY.

WHEN so-called interchangeable work has to be turned out on a large scale as in fuse manufacture, drawings are sometimes dimensioned in such a way that the limits allowed for variations in dimensions cross each other. For example, suppose that a plug having a nominal diameter of 1 in. is to fit into a hole 1 in. nominal diameter, the plug might be dimensioned 0.998 in. high, and 0.994 in. low, whereas the hole might be 0.997 in. low and 1.001 in high. In such a case the high plug would not go into the low hole on account of the limits crossing.

Work produced on this system is not truly interchangeable in the sense that any plug would go into any hole, and it is only possible to assemble such work as "selective assembly," or in the colloquial language of the workshop by "marrying" the parts. Selective assembly or "marrying" is permissible where all the parts are finally brought together in one place in which the final assembling is done, but would be quite inadmissible where spare parts had to be sent to replace any which might wear out, as under such a system there would be no certainty that the spare parts would go into place.

Fuse Manufacture

In fuse manufacture where fuses are finally assembled and examined once and for all, and where the parts do not afterwards need to be replaced, the system is found to be workable and is actually in common use, its advantages being that wider limits of error and therefore easier processes of manufacture are permissible than would be the case where absolute interchangeability is necessary. It will thus be seen that interchangeability in manufacture as commonly understood is of two kinds, viz., the selective and the absolute.

In these days of high-class manufacturing methods and improved processes it is a great question whether selective assembly should not be considered as a survival of old methods and as an unnecessary compromise, as it has been found by some of our best makers of articles produced in quantities, that, by laying out the processes of manufacture in advance under a thoroughly well-considered system, absolute interchangeability is obtainable at no greater cost and with much more satisfactory results than selective interchangeability.

The matter is one which has assumed very great importance recently owing to the fact that so many parts of fuses, shells and various mechanisms which have been required in large quantities for the purpose of the war have been given out for manufacture separately and to different makers all over the Empire, and elsewhere.

In some cases manufacturers of such parts have found that the limits allowed could be decreased with great advantage even from a manufacturing point of view and with the greater certainty that the parts when made would go together and produce the final mechanisms with less trouble at less cost and with better final results than by the selective method.

The matter is one worthy of the most careful attention of manufacturers before beginning to make tools, working gauges, and other appliances necessary for the proper production of repetition work.— Herberts' Monthly.

ECONOMY AND EFFICIENCY OF COPPER CYANIDE.*

By C. H. Proctor.

IN the past, copper solutions have been prepared with various materials. The majority of platers used so-called copper carbonate, which is in reality a sub-sulphate of copper, the metal contents of which vary from 45 to 52 per cent. Some platers are still preparing solutions with copper acetate, which tests in the neighborhood of 30 per cent. copper, and others are using cupri-cupro sulphite of copper, which is known in the market as red copper compound, testing about 40 per cent. copper.

Expensive Procedure.

Although the plater knew that of these materials the metal was the only ingredient of value to him, still he was forced to use such impure salts. He, of necessity, had to add about 50 per cent. of inert matter when using the so-called copper carbonate, 60 per cent. when using cupri-cupro sulphite of copper, and 69 per cent. when introducing acetate of copper. You can readily appreciate that, after a few additions of metal salts, the bath became filled with these inert salts and impurities, increasing the density of the bath to such an alarming proportion as to necessitate the dilution of the solution and finally the discarding of the plating bath. The plater realized that this was a most expensive operation, and has therefore looked for a material free from impurities which would make this waste unnecessary.

The silver plating industry first realized the enormity of this waste and silver cyanide has been used in the large silver plating establishments for the past generation or two, having displaced silver chloride and silver nitrate. The platers of copper, brass and bronze who had to deal with base metals have not given this wasteful practice the consideration it deserved, but as the plating of brass and copper is assuming such large proportions, the plater has been forced to give this matter his attention.

Every plater knows that no matter what copper salt is used in a cyanide solution, it must first be converted into a copper cyanide and then cut down with sodium cyanide to form the double sodium copper cyanide. He has endeavored to secure a chemically pure copper cyanide, as with such a material he would introduce into his bath only the active ingredients necessary for results, that is, metal and cyanide, and at the same time eliminate one operation—the conversion of the carbonates, etc., into copper cyanide.

Copper Cyanide Not New.

Copper cyanide is nothing new. It has been available for years, but unfortunately it could only be obtained at a price which made its use prohibitive. The plater has had to continue the use of impure salts. He has had to continue clogging up his solutions with dead salts, which, while they gave results for the time being, forced him to discard, or at least partially discard, the baths when they became too dense. Every plater knows that a dense solution is harder to manipulate and control, and that it requires more current to get a satisfactory deposit. He has had to contend with an unknown factor, the nature of which he had no way of determining. Recently, however, copper cyanide has been put on the market at a price which not only makes its use possible, but which actually results in a decided saving in chemical costs.

Copper Cyanide Chemically Pure.

Chemically pure copper cyanide, testing 70 per cent. copper, the balance of 30 per cent. being pure cyanogen, is now at the disposal of the plater. He knows that with such a chemically pure salt a solution can be made up which will contain only that which is necessary for results, and knowing this, the solution can be controlled with absolute certainty. As the plater is constantly striving to better his conditions and put his plating department on a sounder basis, it will only be a matter of a comparatively short time when this high grade metal salt will entirely displace the copper salts heretofore used in cyanide solutions.

Why should a plater continue using so-called copper carbonate, which contains about 50 per cent. impurities and which must first be converted into a copper cyanide, when he can introduce chemically pure copper cyanide into his bath direct, especially when a solution made up with chemically pure materials can be controlled with absolute certainty? When the bath needs metal, the plater adds it in the form of copper cyanide, and when it requires cyanide, he adds it in the form of sodium cyanide. In other words he is now able to make up a solution which will give the best possible results in the shortest time and remain constant and well balanced.

Chemically Pure Material Solutions.

In the solutions which I will prepare, I will confine myself strictly to chemically pure materials. The copper bath will be prepared as follows:—

Water	5 ounces
Copper cyanide	15 ounces
Zinc cyanide	5 ounces
Sodium cyanide	15 ounces

I will prepare the brass solution according to the following recipe:

Water	5 ounces
Copper cyanide	15 ounces
Zinc cyanide	5 ounces
Sodium cyanide	20 ounces

Of course, by the elimination of the inert salts, the solution will be less dense, the copper solution standing about 3½ deg. Baume. In making up a copper bath I have only used 6 ounces of chemicals per gallon, while to make up a solution of the same metal contents with copper carbonate, I would have to use over 12½ ounces of material per gallon, thus increasing the density over 100 per cent. To make up a copper bath of five gallons to contain the same amount of metal as this solution contains, it would be necessary to use 21 ounces of copper carbonate. To put this in solution so as to obtain sufficient free cyanide for results it would require about 42 ounces of sodium cyanide.

Baume Scale Solution Test.

It is time that the practical electroplater discarded the Baume scale as a test for solutions, as any material that is soluble in water adds to the density of the bath and the Baume scale, therefore, does not give the plater any idea of the condition of his solution. With the constant addition of metal salts which contain large proportions of inert matter, the density will rapidly increase, while the solution may be practically void of metal. The plater must use chemically pure materials or else discard the Baume scale as an index to the condition of his bath.

Relative Cost.

The cost of the copper solution is 12 cents per gallon, while to make up a solution with the same metal content, using so-called copper carbonate, would cost the plater about 25 per cent. more. When we take into consideration that many plants operate thousands of gallons of solution, this economy is a considerable item. On the face of it the metal cyanides appear more expensive. The market price of copper cyanide is from 42 to 45 cents per pound, while the

*From the Bulletin published by Lewis Institute, Chicago.

so-called copper carbonate is quoted at 14 cents per pound.

The plater must not lose track of the fact that copper carbonate or copper cyanide either, for that matter, has absolutely no value as such. It only becomes of value to him when put in solution with cyanide. It is here that the plater saves. He requires only about one-third the quantity of cyanide to put in solution a given amount of copper in the form of copper cyanide as compared with copper carbonate. For instance, the cost of one pound of copper cyanide (70 per cent. metallic copper) put in solution with sufficient free cyanide to obtain an immediate deposit is—

1 lb. copper cyanide, at 42c per lb. .	42c
1 lb. sodium cyanide, 29 per cent., at 22c. per lb.	22c
	.64c.

To put in solution the equivalent amount of metal in the form of so-called carbonate of copper, 50 per cent., you require—

1 lb. 6 ozs. copper carbonate at 14c. per lb.	19¼c.
2 lb. 12 ozs. sodium cyanide, 29 per cent., at 22c. per lb.	60½c
	79¾c

Current Density.

Another factor which must be considered is the current density. It is a well known fact that a dense solution requires a higher electrical pressure, as the inert matter from the metal salts acts as a retarding agent. Of course, the rapidity of the deposit is governed by the ampere law, which teaches us that the more amperes which can be carried upon a given surface the more rapid will be the deposit. The inert matter being eliminated by the use of the metal cyanides, the plater is able to increase the amperage about 25 per cent., and this enables him to reduce the time necessary for results, increasing the output accordingly. He, therefore, is able to turn out more work in a given time without increasing his tank area, which is another decided economy.

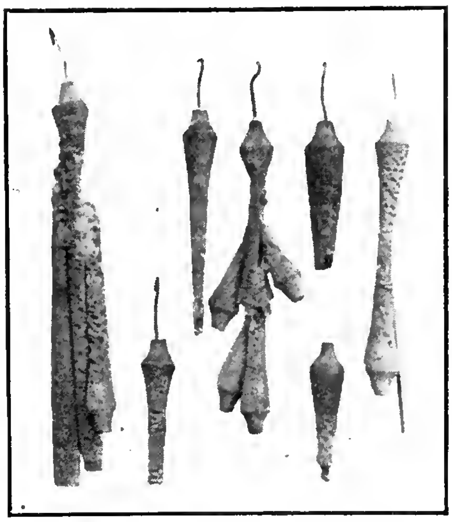
Neither copper carbonate nor copper cyanide as a single factor must be taken then as a basis of calculating their relative costs in the plating solution, but when we take the solution complete, ready for operation, as a basis, there can be no doubt that with chemically pure materials the plater not only obtains a solution of maximum efficiency, but is able to materially reduce the plating costs. Once this fact is brought home, it will be a comparatively short time when chemically pure metal cyanides will entirely displace the materials of doubtful purity formerly used.

Standard Solution.

The fact that all copper salts in a cyanide solution must first be changed to a copper cyanide simplifies matters greatly, as copper cyanide can be added to any copper cyanide solution, no matter what salt was originally used to install the bath in question. The plater has obtained results with materials which were at his disposal, but it was always with a degree of uncertainty as to how the bath would behave. This uncertainty is entirely removed once a plating solution is standardized, and this ideal condition can only be reached with the use of metal salts which are correct from a theoretical and practical standpoint, and it cannot be disputed that the only metal salts which answer these purposes are the metal cyanides.

WELDING UP SCRAP NICKEL ANODES.

SOME important experiments in the welding of nickel anodes by the oxy-acetylene process have just been concluded in the plating department of The Prest-O-Lite Co., Inc., at its Indianapolis plant. As a result of these experiments and tests, worn nickel anodes which have previously been scrapped and sold at less than half-price are now being reclaimed at a saving of more than 100 per cent.



WELDED-UP SCRAP NICKEL ANODES.

The anodes used are castings of 90 per cent. nickel, 8 per cent. carbon and 2 per cent. iron. They are elliptical bars approximately 1½ in. by 3½ in. cross section, by 30 in. long, and weigh about 30 lbs. Their market value varies between 46c and 50c per lb. On the basis of the latter price, each 30 lb. anode has a value of $15.

By welding up old anodes which have been in the solution, and which have a junk value of between 22c and 25c per lb., this concern is now converting its entire pile of scrap nickel into what are practically new anodes at a total cost for gas and labor of less than 6 cents per lb. This estimate is based on a recent test at Indianapolis, in which 421 lbs. of scrap anodes were welded up at the following costs:

463 cu. ft. oxygen, at 2c.	$9.26
480 cu. ft. acetylene, at 2c. . . .	9.60
24 hours' labor, at 25c.	6.00
Total	$24.86

In view of the fact that this test was made before any experience in the operation had been gained, it is apparent that better results and greater savings are sure to be the result of practice. The method of handling this operation is about as follows:—

Operation Features.

As the anodes are eaten away by the solution, they are turned over to an oxy-acetylene welder, who "tacks" on scraps of old anodes by welding to increase the surface. One, two, three and sometimes four pieces of scrap are welded on, depending on the size and weight desired.

The welding flame is also employed to remove the brass hooks which are used to support the anodes while in solution. Under the intense heat of the oxy-acetylene flame (approximately 6,300° F.) the solder melts away rapidly, leaving a pure nickel bar, which is later welded up. Thus, by the addition of from, say, 5 to 15 lbs. or more of scrap nickel, a brand new anode, it is claimed, is manufactured at trifling cost, and every bit of scrap is utilized without the loss of a single pound of metal.

No flux is employed, as this has been found to be unnecessary. The pieces of scrap are simply melted-on or "fused" together, using another piece of nickel as a filling rod. The welding process is of great benefit in obtaining perfect fusion, which is essential, as all joints must have electrical conductivity equal to that of new anodes.

Another advantage is that no skill or experience in the art of oxy-acetylene welding is required to weld up scrap nickel anodes—in fact, any workman with average intelligence can do the work without previous knowledge of the process. The apparatus required to do the work is inexpensive.

Many previous attempts have been made to utilize scrap nickel anodes, the most common practice being to drill holes through several pieces and bind them together by means of lead rivets. This method depends upon the contact of the wire or rivet and the piece of scrap to conduct the current, and is, therefore, of uncertain value, and in many cases a flat failure.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

JOBBING PULLEY PRACTICE.

By J. H. Eastham.

WHILE ordinary pulley moulding is so simple as to call for no special explanation, circumstances occasionally arise in millwright and repair shops that require a little study in order to keep cost of production low enough to cope with competitive selling prices. The foundryman owning a set of pulley patterns of loose rim, separate hub and arm types possesses a

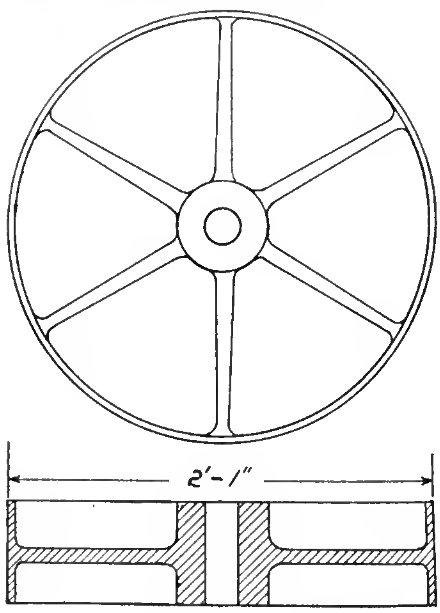


FIG. 1. PULLEY TO BE MOLDED.

valuable asset if he be located in a manufacturing centre, as he is then able to handle rush orders to customer's satisfaction.

The casting 2 ft. 1 in. diameter by 6 in. face, indicated in plan and sectional views of Fig. 1, was ordered to replace

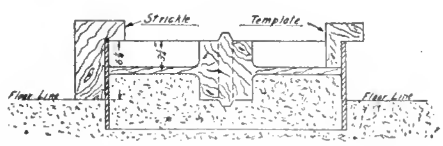

FIG. 2. JOBBING PULLEY PRACTICE.

a breakdown at short notice. The order was received at ten a.m., and was accompanied with the request that the finished pulley be shipped not later than the evening of the following day. The pattern, nearest to size of casting required, measured 2 ft. 4⅝ in. outside diameter, by 10 in. deep, and was used regularly for the production of 24 in. diameter pulleys. The method of molding employed was as follows:—

The rim pattern was bedded into the foundry floor to a depth of four inches, dead level (a most important factor in large pulley moulding), the correct depth

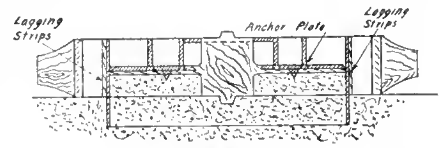

FIG. 3. JOBBING PULLEY PRACTICE.

being gauged by means of the strickle shown to left of sketch in Fig. 2. Following this operation, the inside of the rim was rammed up to within six inches of the upper edge, the arms and lower half of hub being next bedded to place correctly by using the small L shaped template shown to right of the same drawing.

A cheek or midpart approximately 2 ft. 8 in. square by 6¼ in. deep was now placed on the parting left by the strickle above mentioned, and an anchor plate used regularly for the production of 2 ft. 0 in. pulleys lowered on the parting between the arms. Lagging strips 6¼

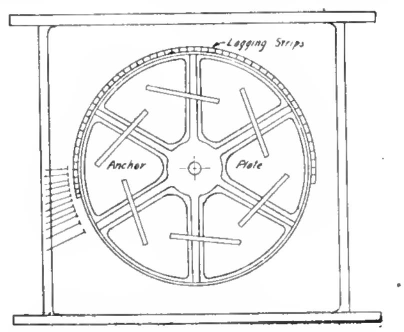

FIG. 4. JOBBING PULLEY PRACTICE.

in. deep by 1¼ in. wide and ½ in. thick were next placed around the outside circumference of the rim pattern to bring up to required diameter, plus contraction and machining allowances; the mould at this stage being shown in plan and cross section by Figs. 3 and 4 respectively.

The cheek and anchor plate were next rammed up to lip of rim in the ordinary way, the upper parting made, the cope rammed up, and guide stakes driven in

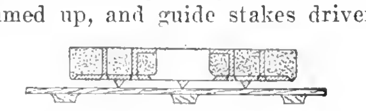

FIG. 5. ANCHOR PLATE ON BOARD.

handle corners. Following this the cope was lifted off and the rim pattern drawn.

The anchor plate with upper half of hub was next removed, the hub pattern drawn downwards, and the plate placed temporarily on a board as indicated at Fig. 5. The cheek was then lifted off, arms and lower half of hub drawn out and finished, and the lower four inches of rim filled in with sand to lower parting level. This operation is shown partly completed at Fig. 6.

The hub core was next placed in position, and the mould closed and made ready for pouring, being so shown in cross section at Fig. 7. With the object of removing surplus weight thrown on the rim owing to the increased diameter, as well as to secure perfect bal-

ance, a cut was taken off the inside of the pulley whilst machining. The finished casting was delivered several hours ahead of schedule.

SAFETY FIRST — THE SHEET METAL PUNCH PRESS.

By J. H. Rodgers.

ONE of the greatest opportunities for the demonstration of "safety first" is in the protection of the operator on the ordinary sheet metal-working punch press.

A very large percentage of accidents to hands and fingers of men and boys in the metal working industries can be traced back to the stamping press, and in many cases when an accident happens, the operator will say that the press "repeated." This may or may not have

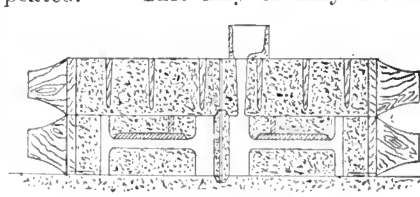

FIG. 7. FINISHED MOLD.

been the case, but, if the press did "repeat," it was due largely, if not entirely, to neglect on the part of the operator in not allowing the latch to engage the clutch pin and thereby release the press.

In the operation of most punch presses the foot is pressed down on a treadle, which pulls the stop latch away from the clutch pin. This clutch pin, by action of a spring, is forced in contact

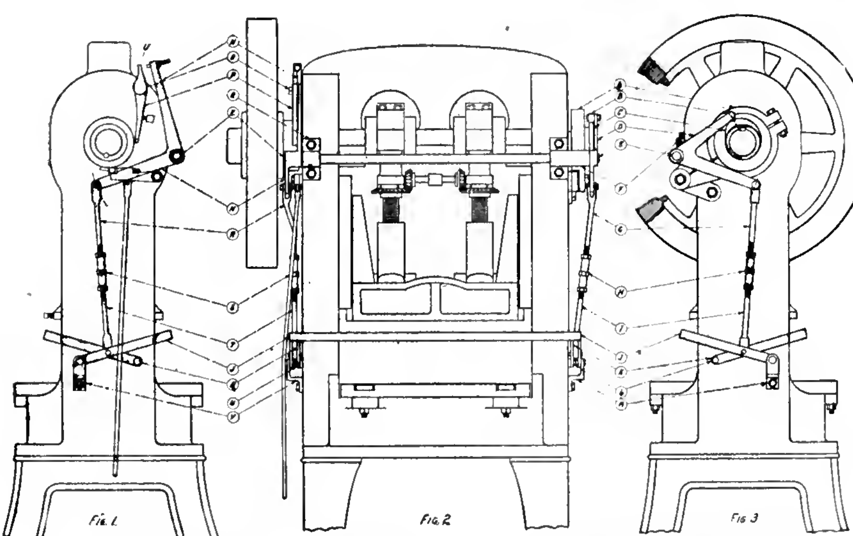
with the clutch which revolves the crank shaft. Removing the foot from the treadle, the latch returns to its former position and engages the clutch pin, thereby releasing the clutch when the shaft has made one revolution.

In many cases the operator, instead of removing his foot, will allow it to return to its former position with the treadle, and it is just at this point that the primary cause of many accidents becomes evident. Many operators, when keeping their foot upon the treadle, do not allow it to raise to its proper position, and instead of the latch engaging with the clutch pin the full amount, in a large number of instances, the contact is scarcely one-sixteenth of an inch.

Now this condition of affairs neither facilitates the operation of the press nor increases the output, while, on the other hand, an opening is left whereby any unforeseen incident, as his chair being jarred, a noise attracting his attention, etc., might cause the attendant to depress his foot before the proper time, and allow the press to operate or "repeat."

Many different styles of guards are now in service to reduce the possibility of accident, and these have had varying degrees of success. To produce a device that will protect (to the maximum) the operator in the performance of his duties, has been for years the desire of many an enterprising mechanic.

The object of this article is to place before the readers of **Canadian Machinery** a safety device for power presses and analogous machines, which has been developed and patented by Wright & Stacey, of Hamilton, Ont., and is manufactured by The Brown, Boggs Co., of that city.

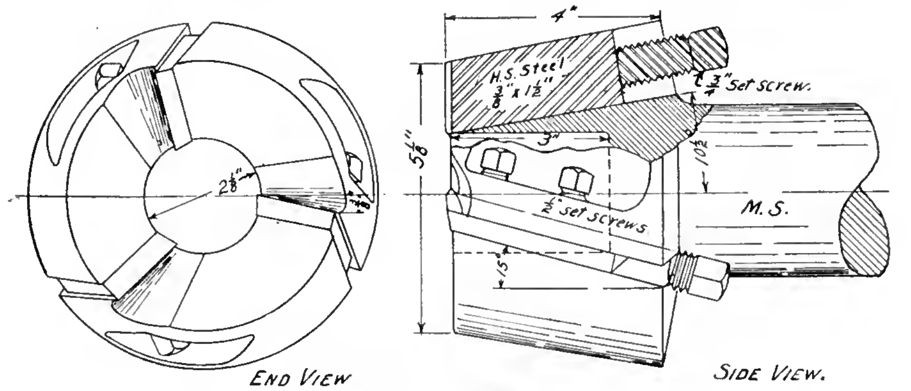


SAFETY DEVICE FOR POWER PRESSES AND ANALAGOUS MACHINES.

Safety Device Features.

The accompanying drawing shows the device applied to a double crank arch press, and protecting both the front and rear of the press. Fig. 1 shows a view from the clutch end of the press; Fig. 2, a rear view; and Fig. 3, a view from the brake end.

Secured to the brake end of the crank shaft is the cam C, which engages with the roller B carried on the upper arm of the bell crank D, which is secured to one end of the shaft E. Connected to the lower arm of the bell crank D are the rods G and I (adjustable with the right and left hand nut H). Rod I supports one end of the guard bars J and K.



A 2-INCH HOLLOW MILL.

Attached to the opposite end of shaft E is the bell crank N, which supports the other end of the guard bars J and K by means of the rods R and T and the adjusting nut S. The stud O carries the stop dog P, one end of which rests against the clutch hub of the press in such a position as to engage with the clutch pin when the crank shaft has moved through a portion of a revolution.

Operation.

The operation of the mechanism is as follows: The treadle of the press is lowered in the ordinary manner, allowing the ram to descend. Immediately the crank shaft—and also the cam C—revolve, the guard descends. If all is clear, the bars J and K will drop to their extreme position and allow the screw U to come in contact with the upper tail of the stop dog P, at the same time removing the opposite end sufficient to allow the press to complete one operation.

If, on the other hand, the operator's fingers, or hand, or any obstruction prevents the guard bars from reaching the safety position, the screw U does not reach the tail of the stop dog P. The opposite end will then engage with the clutch pin and disengage the clutch, stopping the press.

TWO-INCH HOLLOW MILL.

By "Nene."

THE distinguishing feature embodied in the accompanying sketch of a hollow mill is the angle at which the tools are set into the holder. This method gives greater clearance for the cuttings, causing them to curl outwards clear of the work. It also contributes to the free cutting properties.

The body of the tool is of machine steel, the grooves being milled at the desired angle, and not quite equidistant to avoid chattering when in operation. The three inserted cutters are of high-speed steel.

Each cutter is held firmly in position by two ½-inch set-screws and is adjusted to position by the ¾-inch set-screw shown. The holes for these latter screws are drilled and tapped before the cutter slots are milled. The tool was designed for 2-in. work, but a limited adjustment above and below this size is obtained by retarding or advancing the cutters in the slots.

The satisfactory nature of the work done by this tool may be estimated by the fact that locomotive cross-heads and knuckle-pins have been reduced from a diameter of 4½ in. to 2 in. for a length of 1½ in., and threaded in the space of 2½ minutes.

BALL-BEARINGS FOR MILL LINE SHAFTING.

BALL-BEARINGS have now reached such a high level, both as regards design and manufacture, that the thoughtful works manager is asking the ques-

tion as to whether they can help him to overcome the very many troublesome bearing questions which confront him. The surest and safest answer is that given by the history and development of the ball-bearing industry, and is such that any doubt regarding their efficiency and reliability is soon dispelled. The idea of substituting the action of rolling for sliding is as old as anything we know of. The earliest application of this principle we find when heavy structures are moved by using pieces of tree trunk to act as rollers.

Owing to the specialization necessary for cheap production, the average engineer looks upon a ball-bearing as an unknown quantity, which is entirely due to the lack of information. The efficiency of a ball-bearing should not be less than 98 per cent. The co-efficient of friction of 0.0012 relative to the shaft diameter can be compared with the co-efficient of friction when surfaces rub against each other when under load. Should the co-efficient for the ball-bearing be higher than given above, an excessive amount of sliding instead of rolling is taking place, which owing to the smallness of the surfaces in contact would result in wear; therefore, sliding must be avoided. This is where the ball-bearing is superior when compared to the roller bearing, with which sliding always takes place, and thus gives a high co-efficient of friction when compared with a ball-bearing.

Ordinary Bearing Losses.

The efficiency of mill line-shafting on ordinary bearings is variously estimated by different authorities at between 60 to 70 per cent., the lowest value generally being favored. The loss of efficiency is due to the following causes:—

(a)—Power wasted due to sliding friction of the shafting.

(b)—Belt and rope losses, which easily become excessive when the speeds are high for the size of rope or belt adopted, and thus causing undue creeping.

(c)—Power wasted when the shaft is unduly out of line, and at every revolution a certain amount of power is taken in bending it.

Eliminating Friction Losses.

All these evils can be reduced by using ball-bearings.

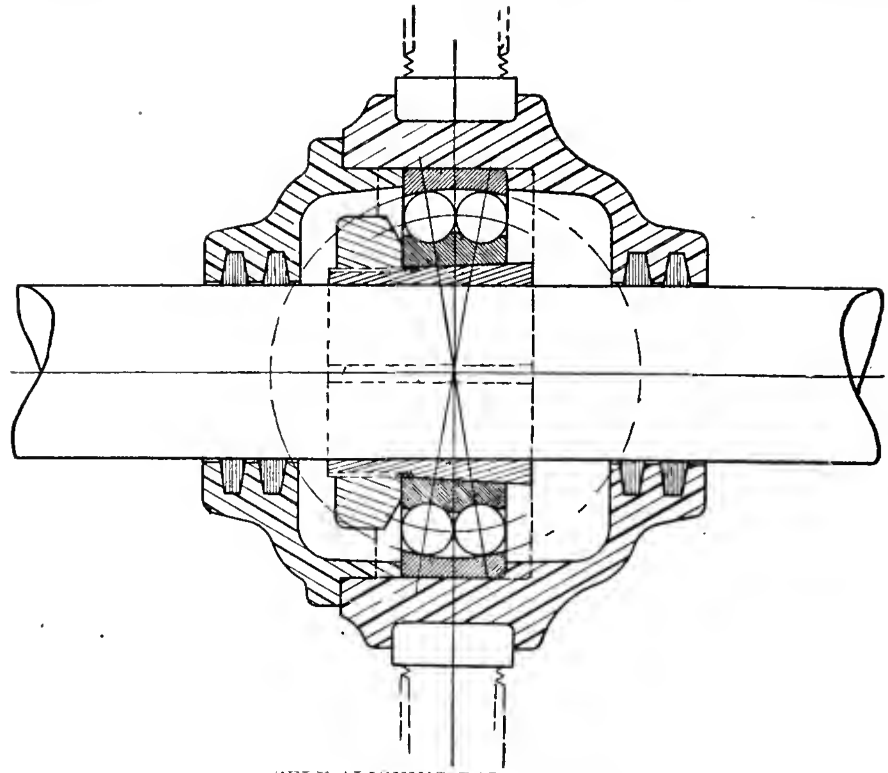
The loss due to friction for all practical purposes ceases to exist by substituting ball-bearings. The efficiency of the line-shaft due to this loss is raised at least 20 per cent., and since no energy is wasted at the bearings, the danger of them running hot is avoided.

Belt and rope losses are reduced by arranging the shafting to run at any speed required, and, mounting on ball-bearings, speeds of from 200 to 600 revs. per minute are not uncommon; the speed depending upon what is required and not upon the limit imposed by the bearings. When the shafting is run at a high speed upon ball-bearings the initial cost is reduced from 20 to 50 per cent. of that for a line-shafting upon plain bearings; this is brought about by using smaller pulleys and shafting for the same belt speed and pull. Besides the saving in power and the initial cost, the smaller dead weight supported by the columns is reduced.

The bending of the shafting can be entirely overcome by using wall brackets or hangers, which permit of easy adjustment. With the increased efficiency of line-shafting upon ball-bearings, a smaller power unit can be used for driving, so that a saving occurs both in the consumption of power and the capital outlay. A return of over 100 per cent. upon the capital outlay of the bearings is the rule; however, when the existing shartings is of larger diameter and has swells, and runs at a comparatively slow speed, the figure is reduced, but it is very seldom below 40 per cent., even in the very worst cases. Ball-bearings only require their housings to be filled with a suitable lubricant two or three times per annum.

Shafting upon ball-bearings is free from wear, which cannot be said of shafting running upon plain bearings, and when the atmosphere is of a gritty nature this wear becomes serious.

The illustration shows design of ball-bearing which has proved successful mounted in a cast-iron housing suitable for holding in a hanger frame. It is self-aligning, the alignment taking place by the frictionless rolling of the balls upon the spherical inner surface of the outer race of the bearing. The nut which forces the inner race of the bearing along the sleeve causing same to contract and grip the shaft, must be screwed up in the opposite direction to that of the rotation of the shaft. The diameter of the screwed plungers must be sufficiently large so as to prevent distortion of the housing. For each independent line of shafting one bearing only must be held sideways in the housing to keep the shaft in position as shown by full lines; all other bearings must be free to move sideways in the housings as shown by dotted lines.—The Power User.



SELF-ALIGNING BALL-BEARING.

Torpedo Balance Chamber. — The mechanism that determines the depth at which a torpedo runs is regulated first by a swinging pendulum and secondly by a valve kept in place by a spring, but which is forced in by the pressure of the water whenever the topedo sinks lower than a certain depth. The valve can be adjusted to any depth by the spring. Both pendulum and valve are connected to the horizontal rudders outside the torpedo.

Winnipeg, Man.—The contract for putting in the sub-structure for the huge cantilever bridge to be built over the Nelson river at Manitou rapids, for the Hudson Bay Railway has been awarded to Robert McDonald, of Winnipeg.

CONCERNING SEMI-STEEL.

By "Melter."

MUCH has been said from time to time concerning the advantages and disadvantages to be derived from the addition of varying proportions of steel to cast iron, and melting in a cupola to produce commercial castings. Whether this can be done beneficially depends on local conditions involving size, shape and requirements of castings. The production of castings, soft or hard, irrespective of size or service conditions are also factors to be considered, although these ultimately resolve themselves into a question of cost. Generally speaking most castings require strength, so we shall consider this variety.

To appreciate why it is practical to use steel in the mixture or otherwise, something must be known of the factors influencing the strength of cast iron and the main differences effected by the use of steel. As the elastic limit is near the point of rupture in cast iron, it is necessary to get an iron having a high ultimate strength. That the elastic limit is near the ultimate strength is demonstrated by the fact that it is impossible to detect any difference other than that the deflection is proportionate to the load until just before failure.

The Strength Feature.

Strength depends on the size and percentage of graphite flakes, percentage of combined carbon, size of crystals of solid solution (iron, carbon, silicon), amount of oxide and impurities (sulphur, phosphorus, silicon and manganese).

Size of graphite depends on pouring temperature, rate of cooling, time iron has been molten before being poured, per centage of metalloids and total carbon. Graphite dissolves in the iron at temperatures below the melting point and therefore it is only the combined carbon on which the fusibility of cast iron depends. The fluidity is determined by the temperature of the metal, percentage of oxide, percentage of phosphorus and silicon, and the effect the metalloids have on the total carbon as well as the percentage of carbon.

Shrinkage.

Shrinkage is a great factor in using steel, and is dependent not only on the composition but on the size, shape, rate of cooling and whether the casting is made in dry or green sand. Anything that ultimately gives more combined carbon in the finished casting gives more shrinkage. If the iron be cooled quickly, the graphite carbon has not enough time to separate out, therefore the casting is hard and there is more contraction. Fluid contraction of course is quite another thing, as this is caused by bad design or in castings where one section solidifies before the other, the remaining fluid section having no molten iron to draw from its adjacent parts with a resultant cavity or shrink hole.

If, by the use of steel, the total carbon content is lowered, fluid contraction is increased. Fluid contraction can be overcome by the judicious use of chills, gates and risers. Shrinkage is not always uniform, in fact high total carbon, or low total carbon with high graphitic carbon expand before shrinkage, which expansion is due to the separation of graphite. During subsequent shrinkage there may be periods when expansion takes place due to the solidification of phosphide entectic (Steadite), and another expansion may take place when the iron changes from the alpha to the gamma state which would be about 1,300 degs. Fah. By actual measurement a few curves have been made relative to the amount of first expansion and total shrinkage, the results being tabulated as follows:—

% steel	% scrap	Si.	Mn.	S.	P.	CC.	GC.	TC.	Relative Expansion	Contraction	Chill	T/S sq. ins.
0	92	2.18	.54	.162	.691	.94	2.41	3.35	1½	28	1-16	22,800
7	77	.68	.50	.12	.391	1.00	2.60	3.60	0	36	1-16	31,200
20	50	1.50	.60	.134	.474	.80	2.70	3.50	2	26	¼	27,000
25	50	2.26	.60	.104	.526	.80	2.46	3.26	1½	28	⅜	....
30	50	1.48	.59	.14	.415	.99	2.85	3.84	4	27	⅜	32,700
30	50	1.30	.55	.127	.454	.76	2.19	2.95	3½	22	¼	32,800

From my observations it was noted that the expansion depends on the graphitic carbon and the contraction on the amount of combined carbon irrespective of the quantity of steel in the mixture. I have obtained the same physical results with the air furnace, and with cupola melting without using steel, simply employing varied proportions and compositions of scrap.

Quantity of Steel.

The quantity of steel used depends on the section of the casting and whether machining be necessary or not. If the casting have light and heavy sections it is not easy to select an iron which will run well and be free from spongy spots, etc. Steel in cast iron is said to give greater strength which is true if the composition is arranged accordingly but where fluid hot iron and small sectioned castings are the requisite, the silicon and phosphorous has to be increased to such an extent that the strength is reduced correspondingly. We know silicon and phosphorus are detrimental to good castings as regards their strength, machining qualities and softness, therefore a happy medium in the percentage of steel added for light castings must be found. In very heavy work semi-steel is economical, as it gives a uniform fracture which it is not possible to get with ordinary cupola iron mixtures; the ultimate strength is also high.

For hydraulic work, machine bed ways or places where wear is a factor, when superheated steam is in contact with fittings, for grate bars and furnace parts, semi-steel, when used in the right chemical proportion, is efficient. The table gives suggested analyses and proportions of steel in various mixtures.

Service.	Si.	M.	S.	P.	% Steel
Loco. cylinders and piston rings	1.0 to 1.3	.8	.06	.50	20
Corliss engine cylinders	1.6	.85	.06	.72	20
Automobile cylinders	2–2.25	.75	.07	.40	12½
Hydraulic press beds	1.6	.80	.06	.5	30
Grate bars and heat resisting castings.....	2.0	.80	.07	.30	40
Auto. piston rings	1.8	.35	.08	1.0	10
Auto. castings (fairly heavy)	1.8	.80	.07	.40	20

CALCULATION OF SHAFTING.

By J. A. Adie.

IN the design of machinery, one of the most difficult questions to decide is the minimum size of the shafts to be used to perform a given amount of work. This question is generally one of the first which must be solved, approximately at least, owing to its influence on the shape and size of the other component parts of the design. If our shafts are larger than need be, it often means, beside the waste of material, that a larger pinion, for example, must be used, so that we may have sufficient metal below the roots of the teeth. This for a given ratio of gearing would increase the distance between centres of gears and consequently necessitate a larger and correspondingly cost-

ly frame or housing. It can be readily seen that, as a larger shaft also requires a longer and heavier bearing, the cost of manufacturing is intimately connected with the sizes of shafting used.

The Starting Point.

As the problem usually presents itself, we are given either the belt-pull or tooth-load of the pulley or gear mounted on the shaft, or a very common form is to know the horse-power to be transmitted and the r.p.m. which the shaft makes. In either case, the first thing we must discover is the torsional moment or twist on the shaft in inch-pounds, and we must also find the direct load supported by the shaft considered as a beam. The torsion in the first case will, of course, be the belt pull or tooth load multiplied by the radius of the pulley or gear in inches. In the second case, the twisting moment T may be found by the formula

$$T = \frac{63025 \times \text{h.p.}}{\text{r.p.m.}}$$

If we had only to consider torsion, the question of shaft sizes would be very simple, but this is hardly ever the case, as there is nearly always a load causing a bending movement in the shaft, in addition to the force tending to make it rotate. The torsion is always caused by some force applied at the end of a lever-arm or at the rim of a wheel or gear, this force tending to bend the shaft. If the lever or wheel be placed on the shaft midway between two bearings, the bending moment B will be $\frac{WL}{4}$ where W = force in pounds and L = length between supports in inches, or if placed outside a bearing as in case of an overhung gear, B = WL.

Determining the Total Stresses.

Now, to arrive at an idea of the total stresses in the shaft, we must combine the bending and twisting moments and obtain what is called the equivalent moment. As the bending moment acts at right angles to the twisting moment, it can be seen that the equivalent moment is somewhat as the hypotenuse of a right-angle triangle, or $\sqrt{(B^2+T^2)}$. The formula as given by different authorities varies somewhat. Rankine gives the equivalent bending moment as

$$\tfrac{1}{2}B + \tfrac{1}{2}\sqrt{(B^2+T^2)}.$$

A shaft will stand twice the strain in bending that it will in torsion, as the axial moment of inertia $\frac{Pd^2}{16}$ is twice the polar moment of inertia $\frac{Pd^2}{32}$. Thus the preceding formula may be written $B+\sqrt{(B^2+T^2)}$ = equivalent twisting moment.

Reauleaux gives the value $\tfrac{3}{8}B + \tfrac{5}{8}\sqrt{(B^2+T^2)}$ = equivalent bending moment, while another formula which has been used very successfully makes equivalent bending moment $= \sqrt{(B^2+.5T^2)}$.

Having found the equivalent twisting moment Rr, we may arrive at the diameter (d) of the shaft required from the formula

$$d^3 = \frac{16Rr}{PS} = \frac{5.1Rr}{S},$$

S being the allowable stress per square inch in the shaft, a safe figure to use for ordinary mild steel shafting being 8,000 lbs. per sq. inch. If we find the equivalent bending moment, Bm, the formula becomes $d^3 = \frac{32Bm}{PS} = \frac{10.2Bm}{S}$, using the same value for S as before.

Other Considerations Affecting Diameter.

Now, while a shaft chosen may be of ample size to safely bear all the strains that may come upon it, we may find it necessary to increase the size on other considerations. A long shaft has a tendency to twist through a certain angle at one end, relatively to the other end; it should therefore be examined as to this angle of torsion at maximum load. The angle of torsion in degrees will be $\frac{583.6Rrl}{d^4G}$, Rr being the twisting moment. l the length in inches and G the torsional coefficient of elasticity = 12,000,000 for steel shafts. The allowable angle of torsion should not exceed .75 degree per ten-foot length of shaft

A shaft should also be examined for deflection or springing between supports, which might be sufficient to throw a pair of gears out of correct mesh, or in case of a shaft transmitting motion by means of levers, would cause considerable lost motion. The deflection can be ascertained by the common formula for beams of circular section and should be limited to 1/300 of the span between supports.

Deflection Example.

Supposing that we require a shaft to transmit 50 h.p. at 150 r.p.m. and driven by a 36-in. gear placed immediately outside the shaft bearing. The turning moment will be $\frac{63025\ \text{h.p.}}{\text{r.p.m.}} = \frac{63025 \times 50}{150} =$ 21,008 inch lbs.

The tooth load on the gear is $\frac{21{,}008}{18}$ = 1,169 lbs. Taking the distance from the centre of the gear to a point of support somewhat inside the end of the bearing as 5 in., then the bending moment will be 1169 × 5 = 5845 inch lbs. The equivalent twisting moment will be $5845+\sqrt{(5845^2+21008^2)}$ = 27,645 inch lbs., then $d = \sqrt[3]{\left(\frac{5.1 \times 27645}{8000}\right)} = 2.6$ in., the size of shaft selected being $2\tfrac{3}{4}$ ins. According to Reauleaux's formula, the equivalent bending moment is $\tfrac{3}{8} \times 5845 + \tfrac{5}{8}\sqrt{(5845^2+21008^2)}$ = 15,800 inch lbs., then $M = S\frac{I}{C}$ or $15{,}800 = \frac{Pd^3}{32}$, whence d = 2.71 ins., or $2\tfrac{3}{4}$ ins., practically the same result as before. M = bending moment, S = stress per sq. inch, $\frac{I}{C}$ = section modulus of shaft.

Using the third formula mentioned, $\sqrt{B(B^2+.5T^2)}$, equivalent bending moment $= \sqrt{(5845^2+.5 \times 21008^2)}$ = 15,963 in. lbs., and $15{,}963 = 8{,}000\frac{Pd^3}{32}$, whence d = 2.73 ins., being about the same as in the two former cases.

Since the gear in this instance is located close to the bearing, we may omit to examine this shaft for deflection. Supposing, however, this shaft to be 8 ft. long, the angle of torsion will be

$$\frac{583.6 \times 21008 \times 8 \times 12}{2.75^4 \times 12{,}000{,}000}$$

= 1.72° which is below our limit of .75° per foot of length. The foregoing methods relate to revolving shafts only.

There is also a class of shafts in which the motion is oscillating and the angle of movement small, as for example shafts carrying brake levers, operating levers, etc. These shafts may transmit heavy torsional and bending moments, but on account of the small angle of motion, it will be sufficient to calculate them for bending only. The deflection and angle of torsion is especially important in this case and should be carefully ascertained, as a small amount of loss motion will reduce the effectiveness of a brake lever very seriously.

CONCERNING BELT SLIPPAGE

By N. G. Near

WITH reference to R. McLaren's recent contribution "Concerning Belt Slippage," it was I who wrote the article to which he refers in "Woodworker." I will therefore endeavor to

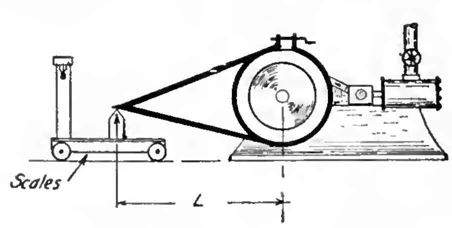

FIG. 1. CONCERNING BELT SLIPPAGE.

explain more clearly why each per cent of belt slippage costs one per cent of

the coal pile, or, as stated in the article, why a slippage of 5.2 per cent. will waste 5.2 per cent of the coal pile.

I will use the example Mr. McLaren cites—a hoisting engine—as it is an ideal one to use. This engine, sketched in the figure herewith, is so arranged that it will raise a weight of 33,000 pounds one foot high in one minute, which is equivalent to doing the work of one horse power. Now, when there is no slip in the "clutch ring" which I have shown, all of the mechanical energy delivered by the engine will be expended in lifting the weight. However, on giving the matter thought, it will be clear to any reader that Mr. McLaren is wrong when he says—"If the clutch be applied to slip so that the weight is raised ½ ft. in one minute, only ½ horse power of work will be performed, and about half as much coal will be used, instead of half the coal being wasted as 'woodworker' claims."

I will explain it in this way:—Let us assume that the 33,000 pounds weight does not move upward at all, while the engine is running at normal speed. The weight is hanging there and is certainly exerting a tension of 33,000 pounds through the cable. It is being held there by the "friction" of the clutch ring. If there were no friction the weight would fall. Therefore, the engine is doing work even though the weight does not move a millionth of an inch. In fact, the engine is doing just as much work as it would be doing if the weight were moving upward at the rate of one foot per minute. This is true for the same reason that in a Prony brake, Fig. 2, the power of an engine is determined by measuring the pressure P on the scales, multiplying it by the "theoretical" distance through which it moves in one minute (which is 2LTTN) and dividing by 33,000. The brake and scales do not move at all, yet. power is being developed.

In the case of the hoisting engine and the 33,000 pound weight, the case is identical. In fact, many Prony brakes are designed on that very principle, i. e. with suspended weights. The behavior of the engine—cut off, etc., is just the same when the suspended weight is not moving as when it is. The only way in which the power could be reduced with a weight moving more slowly would be to "gear down" the speed of the cable; then, the horse power delivered by the engine would be directly proportional to the speed at which the weight is being raised, neglecting transmission friction through gearing, and assuming that there would be no slip in the clutch.

The same is true with belts. If we had a belt that did not move at all, but in which the tensions were the same as when pulling full load, the engine would be dissipating energy at the same rate at which it is spent when pulling full load. We would then have a belt-Prony-brake. Where belt slip is 50 per cent, one half of the fuel is wasted, and where there is no belt slip, no fuel is wasted on that account, but it is always directly proportional to the slip except in cases where tensions change while slip takes place. Usually, though, where slip is 5 per cent or thereabouts there is very little change in belt tension, if any.

For these reasons, in gasoline engine belts, where speed fluctuations are often rather violent, the slip occurs at the time when tensions are greatest and therefore each per cent of slip represents more than one per cent of fuel loss.

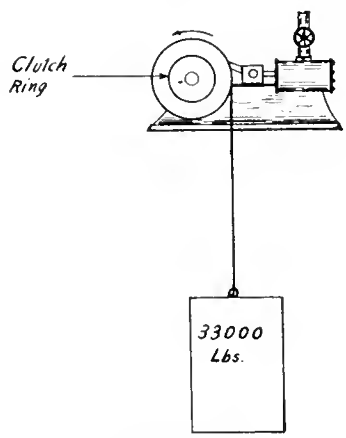

FIG. 2. CONCERNING BELT SLIPPAGE.

A slipping belt is therefore expensive, not only in the cost of the wearing out of the belt, but in the cost of the wasted fuel.

Stimulating Effort.

By J. T.

IT is easy for anyone to criticize; there are, therefore, more critics than boosters. A friendly or kindly word of commendation has often proved the incentive for a worker to go on and do better, it being human nature to esteem admiration and encouragement from one's fellow-man.

A few words of praise may cause a certain type of man to stop his forward march, his reasoning being somewhat as follows: If the boss thinks I am "it," I guess, as things are, I am good enough for keeps. This class of man will never amount to much in the engineering game, and unless he is driven along by harsh words he will not do an honest day's work. In his hours of freedom he will generally be found around bars or poolrooms, or some other equally-to-be-avoided resorts, and no amount of boosting would do him any good. It is a pleasure to know that this kind of man is not very numerous among machine shop operators.

Even if they do not receive any boosting from "the boss," mechanics can depend upon their trade journal for a certain amount of encouragement. I know of more than one man who had the blues and got rid of them by taking his troubles (by mail) to the editor of his engineering paper. The operator will always be sure of getting a number one brand of good advice and some "straight-from-the-shoulder" words of encouragement in addition.

At the present time, when all classes of publications are commenting upon the high cost of living, the engineer is forced to consider success not only from the standpoint of doing his duty in manner that leaves nothing to be desired by his employer, but he must also consider the "cash received for services rendered" side of the question. He may be a perfect success in a small plant, and be absolutely certain that he lacks the skill and experience to handle a better paying situation offered to him, but the fact that his wife and children have insufficient food and proper clothes may tempt him to take the position.

It is difficult to give advice off-hand in a case of this kind, for many men have taken positions above their class. They have done so, however, with a determination to make good and in many cases they have won out. It is nevertheless a dangerous game to play in engineering. Ambition is a fine thing, while grit and common "horse sense" are better, yet absolute necessity has made more "top notchers" than both combined.

The man who shirks his work because he is overworked, underpaid, and never "boosted" has not enough "horse sense" to make a success of himself anywhere, much less in an engine-room. To become a "top notcher," an engineer must never be satisfied that further improvement is impossible, either in his ability or in the equipment under his charge. He must be continually upon the alert to improve conditions, to decrease operating costs, and with these ends in view he may not discontinue his technical journal and engineering book studies.

MOTOR THROWING OIL.

By E. C. Parham.

THE tendency of motor bearings to throw oil, that is eventually drawn into the motor to saturate its windings, may be due to a hot bearing, or to a defective bearing, or to excessive and careless application of oil, or to the overflow pipe being stopped up, or to a pumping action that may become effective as the result of excessive lining wear. In most cases, however, excessive and careless oiling is responsible.

Except where information is furnished

as to the amount of oil required to refill a bearing, or to renew normal loss, it is the better plan to apply the oil through the overflow pipe. By carefully noting the level of the oil in this pipe, while slowly pouring it in, a reliable indication of the oil level in the bearing becomes available. Most caretakers resort to the quicker method of applying the oil through the top opening of the bearing. The objections to this method are that, unless the oiler is careful, he will spill oil outside, or if he is careful, but continues to pour oil in until he sees a little run out of the overflow pipe, the overflow will continue for some time after the oiler leaves, since a certain amount of time is required for the oil to work its way down from above, and up through the overflow pipe.

An inspector was asked to prescribe for an elevator motor that was "throwing oil." The motor windings, brushes, brush rigging, slip-rings, floor and elevator platform were saturated and wherever oil could stand in pools it did. If the motor had been engaged in pumping oil, it could hardly have made a better showing. The inspector cleaned everything concerned with the motor, flushed out the bearings with gasoline, refilled the bearings through the overflow pipe until the oil came up to within $\frac{1}{4}$ inch of the top of the overflow, and then had a heart-to-heart talk with the oiler—which produced satisfactory results.—General Electric Review.

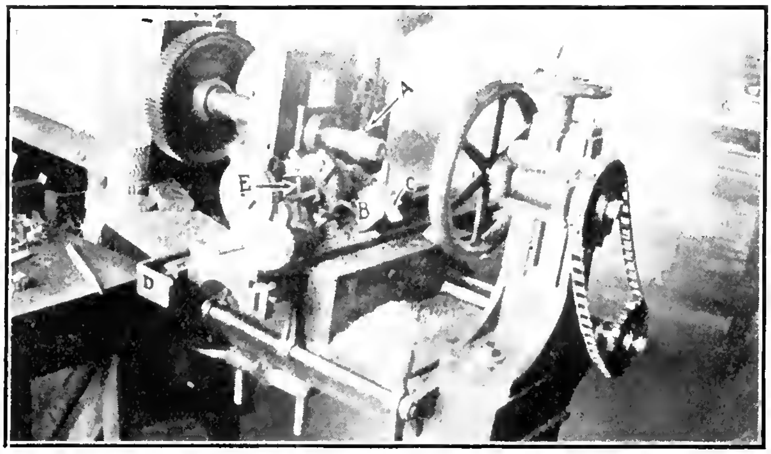
FIXTURES FOR MILLING TOOTHED WHEELS.

By D. A. Hampson.

FIVE thousand specially toothed wheels were required for a new device. These wheels were to have twenty-four teeth, $\frac{1}{8}$ inch high, of $\frac{1}{8}$ inch radius, equally spaced about the circumference. The blanks for the wheels were punched from cold rolled steel 3-16 inch thick and a hole .430 inch diameter was also punched in the centre and finished to 7-16 inch with a reamer. It was required to cut the teeth concentric with this hole within a limit of 0.0015 inch smaller or larger, the diameter being given as 3 inches.

The part of the work to be considered will be the cutting of the teeth and the tools used for the same. Naturally, a low cost for the job was desired; no more of the wheels would ever be wanted and so any special fixtures would have to be thrown away after the completion of the work.

A Lincoln miller in first-class condition was elected for the job and a "stub" arbor of the shortest length that could be used was made up. A pair of B. & S. high-speed formed cutters were purchased—the cutters of a form that finished three teeth at one passage—therefore eight indexings per revolution of the wheels finished one set. The cutter is shown at A in position on the arbor.



FIXTURE FOR MILLING TOOTHED WHEELS.

The headstock from a set of plain index centres was stripped of the worm shaft and the live "centre." In place of these, a tool-steel, hardened arbor was supplied, the arbor carrying a flange $2\frac{3}{4}$ in. diameter, which was bolted to the dogplate of the head. Four wheels were clamped on the arbor at one time. At the tailstock end the arbor was threaded for a large thumb-nut, drilled with a $\frac{3}{8}$ inch drill for tapping, and beyond the threads was turned $\frac{3}{8}$ by 1 inch to go in a hardened bushing in the tailstock. This provided substantial support for the work at the tail end and though the nuts with the shallow thread gave out, the hardened arbor showed no signs of wear. A washer of the ball and socket type between the nut and the wheels prevented any bending of the arbor which might have occurred had any of the wheels been slightly warped.

Before doing the work it was assumed that to try to cut more than four wheels at a time would delay the work, the time involved in loading and unloading the close-fitting pieces, cleaning of chips, and the spring of a longer arbor all being considered. The actual work proved this assumption to be well founded.

Indexing was simplified by having only eight holes to "catch" with the index pin; the other holes on the circle were plugged so that no mistake could be made. A special index pin, E, was made having a long cross bar for easy working and an extension at one end over which a spring was slipped. Then to index from one hole to the next, the operator took hold directly on the worm gear with one hand and as the pin was released with the other hand gave the gear a turn until the pin dropped of itself into the next hole. The pin and spring may be seen in the photo.

A special tail-stock is shown at B. It is a casting fitted with a slide into which is pressed the bushing for supporting the arbor. The slide is clamped by a single nut to which the wrench C is fited, so that it will not come off. Releasing the nut and moving the slide back gives ample room for loading the work with ease and comfort—the tail-stock is made U-shaped to give plenty of clearance around the wheels. The slide joins the U together at the top; a pin prevents the slide from being shoved out too far.

So that no time would be wasted on unnecessary movement, an L-shaped stop, marked D, was made for the table to stop against in the nearest safe distance from the cutter when loading and unloading. The movement for cutting the teeth was such as to just clear the cutter when the wheels were turned and was controlled by a hinged block inside of the "L"—hinged so that it could be swung out of the way when loading (in the photo it is thus, and cannot be seen). Every inch which any operator might unthinkingly move was saved and controlled by parts heavy enough to withstand abuse. Not a single loose piece, excepting one thumb nut and washer, had to be handled.

The hand reverse feed was altered as shown so that the operator could do all his work while seated without moving. A link belt and two sprockets—both in stock—carried the feed to the back shift. One sprocket and the hand-wheel are keyed to a short shaft turning in a sleeve in the tail-stock clamp. A guard, not shown, was provided for the chain.

In service, the whole arrangement was found as nearly ideal as any, not automatic, could be and no changes from the original plan were made. An average of 140 wheels per day of ten hours was turned out, all within the required limits of accuracy and finish. One of the wheels is shown against the headstock and a pile of them are to the left. The cutters milled an average of 600 wheels between sharpenings. Seated, with a bench at his side, the operator had time to remove the burrs between the cuts.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

ENGINE LATHES WITH ATTACHMENTS FOR SHELL WORK.

THE standard engine lathe can be rendered more efficient on shell work when equipped with certain special attachments. These latter can, of course, be readily removed at any time and standard parts applied, thus rendering the machine ready for its regular work. The Niles-Bement-Pond Co. are furnishing lathes equipped with several types of attachments which adapt them to high production of duplicate work in the finishing of shrapnel and different sizes of high explosive shells, both of the solid and hollow-forged types.

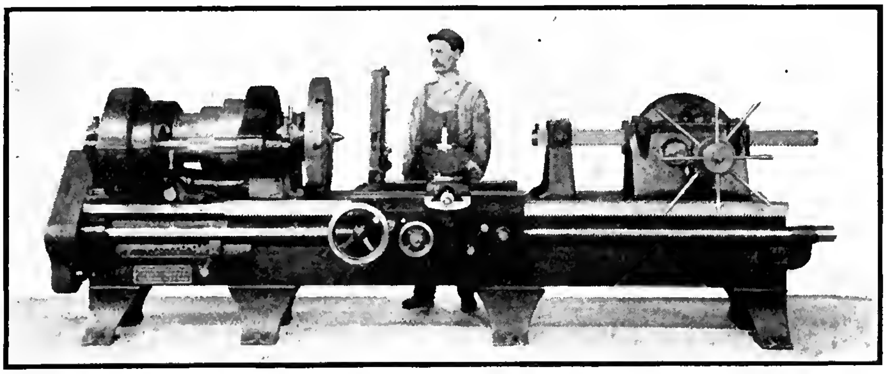


FIG. 1—FRONT VIEW OF 26-IN. DOUBLE BACK-GEARED ENGINE LATHE EQUIPPED FOR BORING HIGH EXPLOSIVE SHELLS.

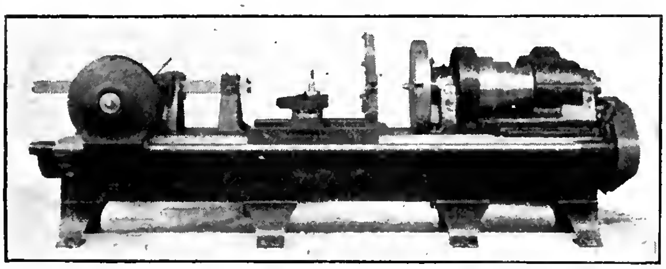

FIG. 2—REAR VIEW OF 26-IN. DOUBLE BACK-GEARED ENGINE LATHE FOR BORING HIGH EXPLOSIVE SHELLS.

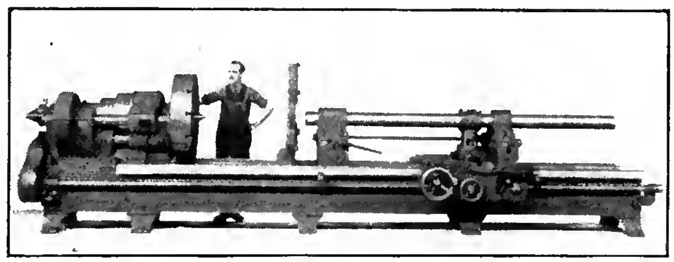

FIG. 3—SHOWING A 36-IN. TRIPLE-GEARED ENGINE LATHE EQUIPPED FOR STRAIGHT OR TAPER BORING OF SHELLS.

Boring Tailstock.

Figs. 1 and 2 show front and rear views respectively of a 26-in. double back-geared engine lathe, equipped with a boring tailstock for boring high explosive shells of either the solid or hollow forged type. With the exception of the tailstock, the lathe is the standard type of latest design with improved features. The boring tailstock and support can be readily removed and a standard tailstock applied for regular work. The interior contour of the shell is obtained by the use of bottoming and forming tools built to suit the requirements of each case.

The tailstock is fitted with a square forged steel boring ram, the latter having power feed by means of a shaft geared to the driving works and running along the rear of the bed. The shaft drives through worm and worm wheel to the pinion and rack on the ram, this giving a smooth, positive motion. Large pilot wheels are provided for hand traverse of the ram and for starting and stopping the feed. The lathe is equipped with quick-change gear feed mechanism. To prevent vibration of tools, the boring ram is provided with a support, which can be adjusted along the bed to a position near the work. A standard tool carriage for turning operations forms part of the equipment, a steady rest being also furnished for supporting either a pot chuck or the shell itself as the case may be.

Attachment for Straight or Taper Boring.

Fig. 3 shows a 36-in. triple-geared engine lathe equipped with a boring bar, mounted on the carriage, and arranged for either straight or taper boring of shells. The boring bar is carried in a bearing with a swiveling base mounted in the carriage. Two supports are provided for the bar, one on either side of the carriage. These supports consist of a bearing for the bar mounted on a slide, which has cross adjustment on a substantial base. For taper boring, the support near the shell is shifted to one side of its central position and the other end support shifted to the other side of its central position. The support bearings have means of swiveling a sufficient amount. The central bearing

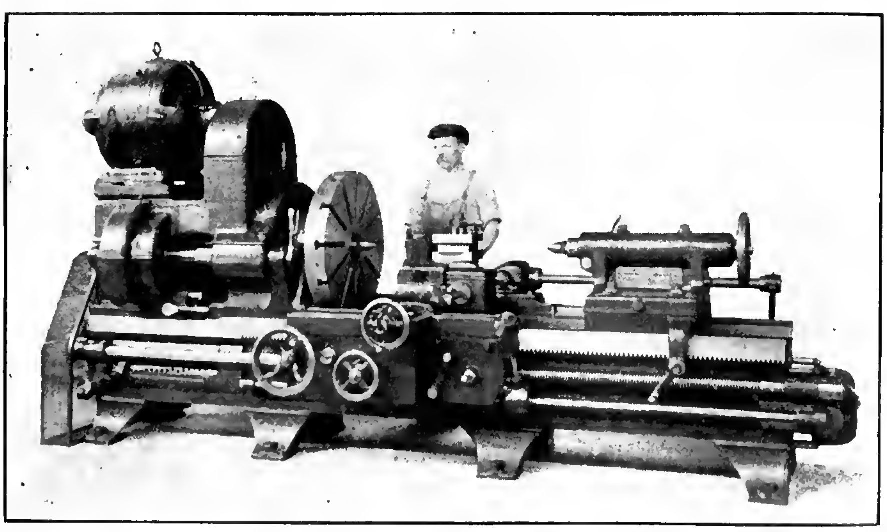

FIG. 4—SHOWING A 30-IN. DOUBLE BACK-GEARED ENGINE LATHE EQUIPPED FOR WAVING AND GROOVING COPPER BAND SEAT OF SHELLS.

of the bar is arranged to slide in and out on the carriage as the bar is fed.

The bar can be adjusted bodily across the lathe so that the cutter can be traversed inside the shell and fed into the work and at the same time always remain at a given set taper. This is accomplished by having the slides of the two end supports connected by screws and gearing so that they move simultaneously when adjusted by the ratchet wrench shown on the support nearest the headstock.

Attachment for Cutting Waves and Grooving Band Seats.

Fig. 4 shows a 30-in. double back-geared lathe of the latest design, equipped with an attachment for cutting the waves and grooving the copper band seats of shells.

The standard compound tool rest has been removed from the carriage and a special rest substituted. This consists of a lower slide, which is mounted directly in the carriage and has cross adjustment by a hand screw. Mounted on this lower slide is a tool slide. In order to obtain the wave effect, this tool slide is given a reciprocating motion parallel with the bed while the projectile revolves. This motion is obtained by means of an eccentric carried on a cross shaft which is journaled in the cross slide. The cross shaft is driven by bevel gears from a shaft located along the back of the lathe. This latter shaft is geared to the main spindle of the head, and suitable change gears are provided for obtaining the number of waves per revolution required on different sizes and types of shells. The eccentric is adjustable to produce the desired amount of the wave, and the depth of the wave rib is determined by the shape of the formed tool.

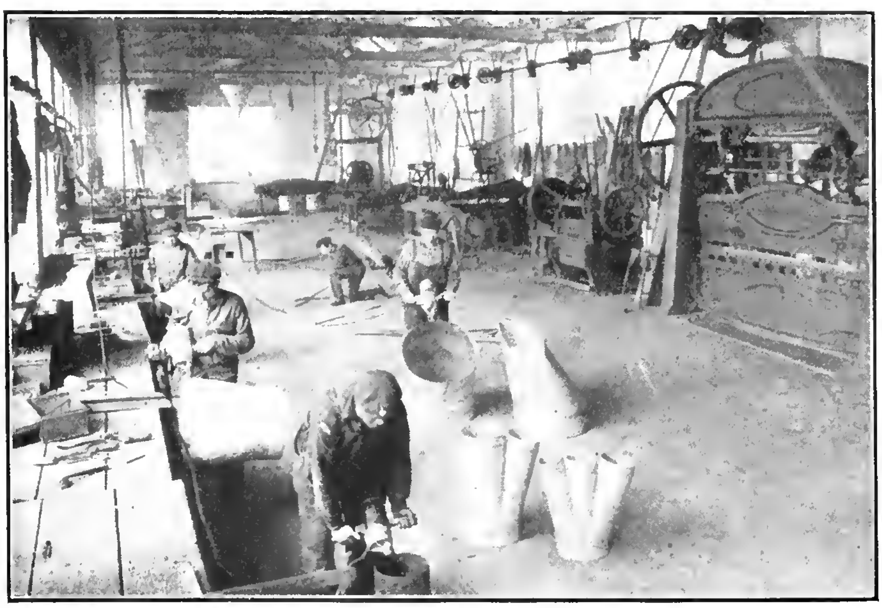
On lathes equipped with this attachment, it is customary to furnish also a four-sided turret tool post on the rear of the carriage. This permits all the operations on the band seat to be performed at one setting of the projectile in the lathe.

PORTABLE ELECTRIC DRILLS.

THE value of portable electric drills in the manufacturing plant is forcibly shown in the accompanying illustration, where electric drills, manufactured by The Standard Electric Tool Co., Cincinnati, Ohio, are being used. They are adapted to many classes of work, as will be noted. These drills are made in all sizes for both small and large work, the small tools having high speed and being very light in weight, which enables operators to drill holes in metal or wood with great rapidity.

Owing to the fact that a lamp socket connection is the only thing necessary to drive this equipment, the cost of installation is only that of the drills, no shafting or belting being necessary. The tools shown are of the universal type which operate on both alternating and direct current. They are employed on outside jobs, such as erecting, or where drilling has to be done. The feature of being interchangeable on either current gives them a very wide range of work.

On large metal sheets, drilling can be done right on the floor, and the difficulty of moving to a punch or drill press is eliminated. The principle of taking the tool to the work is very vividly illustrated here. In cases where the holes have been previously punched and do not match, the electric drill is used for reaming out.

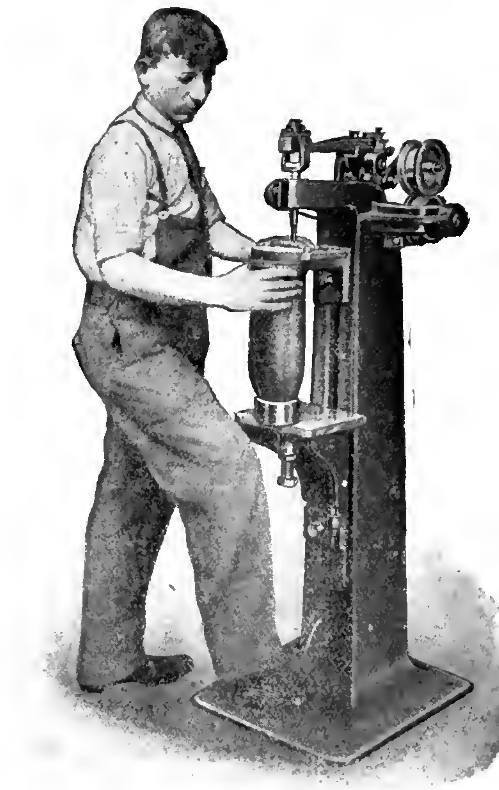


PORTABLE ELECTRIC DRILLS AT WORK.

The illustration shows holes for fittings and attachments to pipes and ventilator sections being produced by electric drills.

ROTARY VIBRATING RIVETING MACHINE.

THE rotary vibrating riveting machine made by the Grant Mfg. & Machine Co., of Bridgeport, Conn., has been especially fitted up to rivet over the base of the explosives projectile shown, in order to hold the gas plate securely in position.



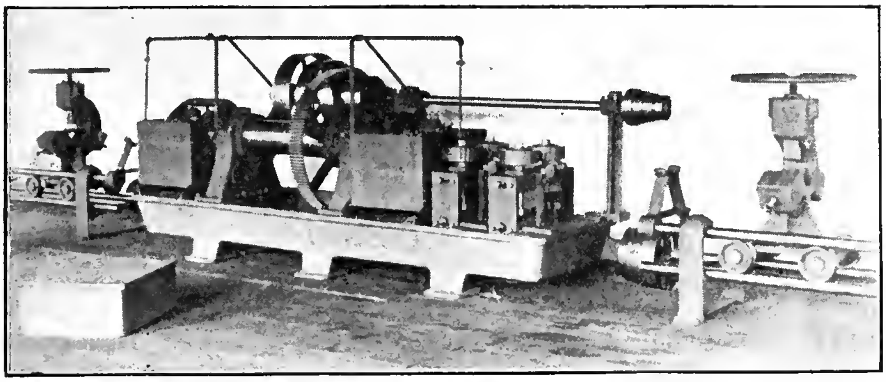
ROTARY VIBRATING RIVETING MACHINE

In order to prevent the possibility of the base of the shell being porous in the slightest degree, the end is recessed and threaded to receive a steel plate, the inner face of the latter being coated with a special cement before being screwed into place. The plate screws down below the back end of the shell sufficiently to allow the base of the shell to be peened or riveted over it, preventing the possibility of its coming loose.

The machine is fitted with a special ball-bearing revolving fixture which fits the nose of the shell before the plug is screwed into the nose, and the base of the shell is supported in a position which brings the vibrating hammer exactly over the joint where the base plug is screwed into the shell. The shell is rotated one complete revolution by hand, and, with the machine striking about 2,000 blows per minute, the plug can be riveted perfectly tight into the base in about ten seconds. With a change of fixtures, the machine can be adapted for 4.5 in., 18-pdr., or shells even larger than 4.5 in.

MACHINE FOR TURNING VANADIUM AND SPECIAL ALLOY STEEL SHELL BLANKS.

THE illustration and description refer to a product of the Brightman Mfg. Co., Columbus, Ohio, the purpose of which is the preparing or rough turning of vanadium or special alloy steel blanks, for conversion later on automatic machines into shrapnel or high explosive shells, the material when so treated being, it is claimed, perfectly round and true to size. With this machine it is possible to turn from 1,000 to 1,500 ft. of 2-in. round material in ten hours, and, taking this as a base, sizes 1 in. and up to 6 in. can be turned and finished in proportionate quantities.



MACHINE FOR TURNING VANADIUM AND SPECIAL ALLOY STEEL SHELL BLANKS.

The rough bar or rod is fed in at one end of the turning machine by a set of feed rolls driven by worm wheels and worms attached to perpendicular and horizontal shafts, a four-step cone regulating the feed. Material, after leaving the feed rolls, enters the roughing head, which reduces it very nearly to size. This head, as well as the finishing head, is composed of a steel cutter and guides set in the segmental slots, which have a screw adjustment. These heads are bolted to a cylinder having hollow bearings, through which material passes in the process of turning, and are driven by a gear and pinion. The latter is attached to a horizontal shaft, on which are different sizes of pulleys to give various speeds to the machine; or the latter can be motor driven. After leaving the roughing head, the material passes through the hollow cylinder into the finishing head, which turns it to size, and ready for the automatic machines.

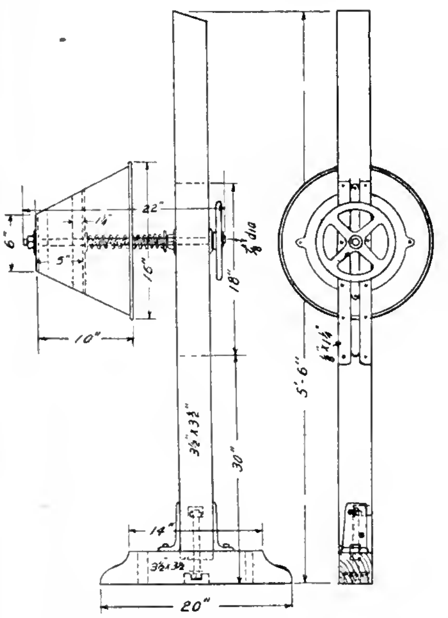


FIG. 2—DETAIL OF CENTRE FOR GALVANIZED PIPE WORK.

The bed of the machine is a receptacle for a soap solution, which is continually pumped on the cutters by a small pump on the rear. This drains back into the bed to be used again. Boxes surrounding the cutter heads are used for chips or turnings, and are so arranged with opening sides that they can be readily cleaned while the machine is in operation. At each end tracks are provided with a gripping device, which keeps material from revolving with the machine.

CENTRES FOR GALVANIZED PIPE WORKING.

By A. E. Granville.

A VERY convenient support for tin or galvanized iron pipe during the beading or crimping operation is shown by Fig. 1 and in detail by Fig. 2. Two of the supports are shown in position at A and B for work done on the machines, C and D. These centres may be raised or lowered to suit by means of the clamps E and F. The centre cones are made of heavy galvanized iron, and are backed by spiral springs, which keep the work pressed securely against the stops G and H on the machines, so that, when set, all the operator has to do is to throw in the clutch and watch the work revolve between the rolls.

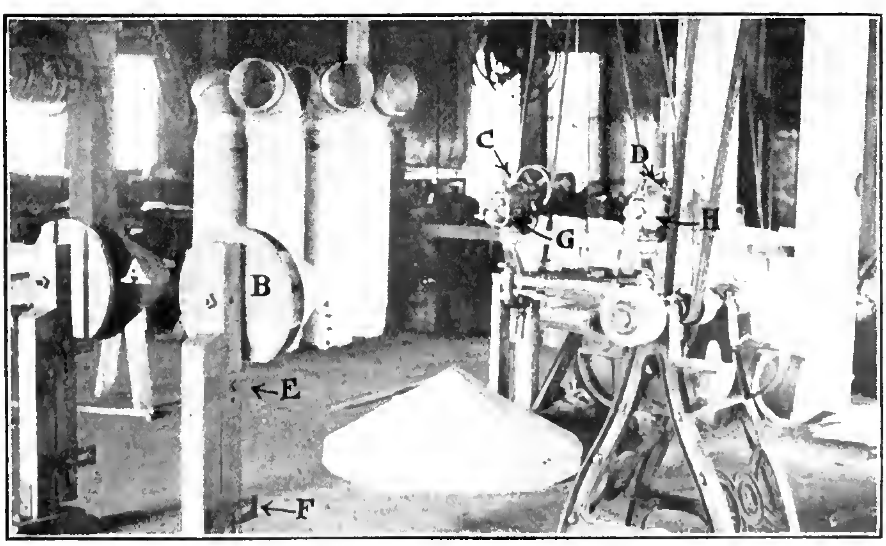

FIG. 1—CENTRE FOR GALVANIZED PIPE WORK.

HIGH RESISTANCE PYROMETER.

OUR illustration shows the high resistance pyrometer manufactured by the Brown Instrument Co., Philadelphia, Pa.

HIGH RESISTANCE PYROMETER.

This apparatus has a resistance of 200 ohms or more: it is therefore applicable to hardening, heat-treating and annealing furnaces where accuracy is a sine qua non. Originally pyrometers were all of the low-resistance type, and it has only been in recent years, we understand, that those of high resistance have become available.

THE COMING FOUNDRYMEN'S CONVENTION.

ACTIVE preparation is being made in every direction for the coming convention at Atlantic City, N.J., the American Foundrymen's Association and allied bodies, and there is little doubt that, when the week of September 27, 1915, arrives, everything will be in apple-pie order for this wide scope function.

The occasion will be marked by the annual meetings of the American Foundrymen's Association and the American Institute of Metals as well as the yearly exhibit of foundry supplies and equipment conducted under the auspices of the Foundry & Machine Exhibition Co. Heretofore, the Associated Foundry Foremen have held their meetings during this week, but since this organization has dissolved and its members have become affiliated as associates with the American Foundrymen's Association, they will take part in the deliberations of this society.

The program of the American Foundrymen's Association, while yet incomplete, has already assumed large proportions and to permit of full discussion of the many valuable papers that will be presented, two simultaneous sessions on malleable and steel castings will be held. The business meeting, which heretofore followed the close of the technical deliberations, will be held on Wednesday evening, Sept. 29, when the new officers will be elected and the business affairs of the association will be discussed.

A gratifying increase in membership has been recorded during the year, the enrollment now approximating 1,000, of which more than 150 are associates. The campaign for new members resulted in the addition of nearly 100 new names, and at the annual meeting it is believed a still further growth will be reported. Financially the society is in better condition than at any time in its history, and the balance in the treasury will permit of increasing the scope of the work that is now being carried on.

A partial list of papers that will be presented, follows:

"Resume of Advances in Foundry Practice," by Richard Moldenke.

"Application of Various Types of Molding Machines to Different Classes of Work," by I. J. Wilson and A. O. Backert.

"Time Studies on Molding Machines," by H. K. Hathaway, Philadelphia.

"Functions of Sand Binders," by H. M. Lane, Detroit.

"The Reclamation of Molding Sand," by W. M. Saunders and H. B. Hanley.

"Relation of the Foundry Foreman to the Manager," by S V. Blair.

"Manufacture and Constituents of Pig Iron and the Essentials in the Purchase of this Material," by O. J. Abell, Chicago.

"Pouring Systems for Gray Iron Shops," by H. Cole Estep.

"Fuel Oil Cupolas," by Bradley Stoughton, New York City.

"Thermal Reactions in Melting Gray Iron," by Dr. Joseph Richards, Lehigh, Pa.

"The Inspection of Automobile Castings," by C. B. Wilson, Pontiac, Mich.

"Defects in Gray Iron Castings and Remedies for Them," by Herbert Ramp, Cincinnati.

"The Value of the Vibratory Test in Steel Foundry Practice," by Lloyd Uhler, Pittsburgh.

"The Particular Application of the Converter in the Manufacture of Steel Castings," by C. S. Koch, McKeesport, Pa.

"Notes on Electric Furnace Construction and Operation in the Steel Foundry," by Mr. Gray, United States Steel Corporation, New York City.

"Correct Proportions and Essentials in Checker Design for Open Hearth Furnaces," by W. A. Janssen, Bettendorf, Ia.

"Causes for Shrinkage Cracks in Steel Castings," by William Bossinger, Marion, O.

In addition to the foregoing, reports will be presented by the committees on safety and sanitation, industrial education, costs, steel foundry standards, specifications for malleable castings, specifications for gray iron castings, specifications for steel castings, and specifications for foundry scrap.

Aside from the many attractions afforded by Atlantic City, the entertainment features will involve a theatre party and banquet, and a committee will be in charge of plant visitation, whose members will direct the visiting delegates to the many interesting foundries in Philadelphia and vicinity. It also is probable that numerous side trips will be arranged to enable visitors to inspect the shops in which they are interested, with the least amount of inconvenience.

Headquarters for the American Foundrymen's Association will be at the Marlborough-Blenheim Hotel. The meetings will be held on Young's Steel Pier, where the registration booth also will be located.

Foundry and Machine Exhibition.

C. E. Hoyt, secretary of the Foundry & Machine Exhibition Co., Lewis Institute, Chicago, reports that the space reservation already made, foreshadows one of the largest exhibitions ever held. Young's Steel Pier is admirably adapted for show purposes, and all facilities are provided for the rapid building and installation of machinery. The exhibition will be opened formally on Saturday, Sept. 25, and will close Friday, Oct. 1.

American Institute of Metals.

The headquarters of the American Institute of Metals will be at the Hotel Traymore, and the meetings will be held either there or on Young's Million Dollar Pier. The provisional programme is as follows:

D. H. Newland, Assistant State Geologist, New York—"Albany Sand."

A. D. Flinn, Board of Water Supply, New York—"Experience with Brass in Civil Engineering Work."

C. P. Karr, Bureau of Standards—"Molding Sand."

Charles Pack, Doehler Die Casting Company, New York—"Aluminum Die Casting Work."

Dr. Burgess and Dr. Merica, Bureau of Standards, Washington, D.C. — "Cracking of Wrought Brass from Overstrain."

William W. Clark, Seymour Manufacturing Company—"Manufacture and Use of Alumino-Vanadium."

C. V. Powell, British Aluminum Company, Toronto, Ont.—"Some Developments in Aluminum."

Russell R. Clarke, Pennsylvania Lines West—"The Advantage of a Standard Railroad Bearing Alloy (The Journal Bearing Shell, not the Lining)."

Dr. Weintraub, General Electric Company—"Silicon Resistance Furnaces for Melting Brass."

G. H. Clamer, The Ajax Metal Company—"Effect of Zinc on Copper, Tin and Lead Alloys."

W. M. Corse, The Titanium Alloy Manufacturing Company—"Copper-Aluminum Alloys."

Jesse L. Jones, Westinghouse Electric & Mfg. Company—"Forging Manganese Bronze."

S. L. Hoyt, University of Minnesota—"Amorphous State of Metals."

S. W. Parr, University of Illinois (Two Papers —"Method of Analysis for Complex Alloys," "Development of Acid Resistance Alloys."

Dr. Rawdon, Bureau of Standards, Washington—"Metallographical Examination of 88-10-2 Alloy."

F. A. J. FitzGerald, FitzGerald Laboratories—"Electric Furnaces for Brass Melting."

H. T. Kalmus, Kalmus, Comstock & Westcott, Inc.—"Cobalt in Non-Ferrous Metals."

Dr. S. Trood, U.S. Sherardizing Company—"The Electric Furnace for Sherardizing."

W. E. Barlow, Virginia Polytechnic Institute.

Thomas F. Wettstein, United Lead Company—"The Effect of the Present European War on the Metal Industries."

Elwood Haynes, Haynes Stellite Works—"Stellite."

Prof. D. J. Demarest, Ohio State University—"Analysis of Babbitt Metals."

EMPIRE SERVICE PRIVILEGE AND OPPORTUNITY.

We have now got well past the inquiry stage as to who started this huge-scale war in Europe, the effects of which become more far-reaching all the time. Its finish is the all-important matter to-day, and this involves both men and munitions on a scale hitherto undreamed of. In the matter of manufacturing shells for the service of the Motherland, what we have already done may be taken as more or less of a preliminary effort only, because in no sense could it be said, except until recently, that our engineering and metal-working plants had mobilized their operative staffs and equipment on a war footing. This consummation has, however, materialized.

As in the matter of munitions' supply so has it been with the enlistment of our men for active service. True it is we promptly met the invitation to furnish both a first and second overseas service contingent, yet notwithstanding, it was but faintly realized, if at all, the nature of the task set our Empire and her Allies, and through them the desperateness of the mission and undertaking in which our fellows had embarked. Heavy casualty lists of more or less daily occurrence during the past few months have had an enlightening as well as a sobering and saddening effect, more especially as in spite of them all, the achievement has been in no wise such as to speedily bring an end to the conflict.

Speaking generally, we are much more alive to the call of Empire to-day than ever before, so much so that we are getting keenly enthusiastic about it. A growing-in-intensity response is being made by much of our manhood to the further invitation to enlist for overseas service. It has come home to us, that, no matter who started the war, we must needs bear a hand in finishing it, both thoroughly and expeditiously. The selfishness to which all of us are in some degree naturally addicted and have consciously or unconsciously cultivated still combats successfully the call for self-sacrifice, for such the call is.

No male in good health and without disability, and unmarried, between the ages of 18 and 30 years, is entitled to be classed as a man who does not in this crisis put his Country and Empire before every other consideration. The one and only immediate career of any real value to-day for our youths and young men is that of a soldier, and it goes without saying that the opportunity let slip now can never be redeemed. Let us get away, therefore, from the everywhere - prevalent, and instilled-in-our-individual-nature, idea that we are too important in some sphere of business activity to be spared, or that we are so highly educated or so richly endowed with this world's goods that it would be infra dig for us to take our place on the firing line and be a target for Germans to shoot at. As good, yes and better than the best, most gifted, and endowed of us, have stood in the trenches of Northern France and Belgium during the past twelve months, and have given their lives for a cause that not a few among us deem very much secondary to self.

There is a place to fill and a part to play in our Empire's cause by every citizen of our Dominion at this time, and none of us need long remain in ignorance of our relation thereto. If we are not actively aiding in the manufacture of munitions of war we should be making appreciable progress towards the trenches, and, if neither, then why not?

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Toronto, Ont., July 20, 1915.—The industrial situation is in much the same position as last week, and no striking developments have taken place. It is, however, confidently expected that further war orders of considerable size will be placed with Canadian manufacturers. The money already expended in Canada on war equipment is enormous, and will go a long way towards making up for the loss of ordinary trade. The situation as regards the shell industry is unchanged, but considerable progress is being made towards increasing the output of cartridge cases and other shell parts necessary for making complete shells. When Canada is in a position to ship fixed ammunition entirely, orders for shells will again be distributed.

The development of foreign trade is being followed with the greatest interest in business circles, and satisfactory results are expected from the efforts that are being put forth. A good start has already been made, and the outlook is favorable for considerable business in the future.

Steel Markets.

There is a continued heavy demand for bars and forgings for shells, and the entire production of the mills is being rapidly absorbed by our various shops. Although the forging plants have con-

siderably increased their output during the last few months, it is yet hardly sufficient to meet the demand from machine shops. When larger orders for 4.5 shells come to be placed, as they will be, it will mean increased activity at the forging plants and possibly in some cases the installation of more presses.

Merchant business continues quiet, there being hardly any material improvement in the building trade. There is a fair demand for bridge sections, and some inquiries for reinforcing bars have been sent out. The steel pipe trade is comparatively quiet, although the City of Ottawa is in the market for a quantity of 51-in. pipe. Prices of steel products are holding firm.

There is no change in the galvanized sheet situation, as the trade is not inclined to buy spelter at the present price, which is too high to use for sheets. Some mills are refusing to take contracts under present conditions. Galvanized pipe is very firm.

Favorable conditions continue in the steel trade in the States, and production is increasing to keep pace with the demand. There is a heavy demand for bars for shells, and some large contracts have been made. The United States Steel Corporation has advanced quotations on bars, plates and shapes for current or third-quarter delivery to 1.30 Pittsburg.

Pig Iron.

There is no change in the situation as regards Canadian furnaces, although it is stated that a considerable tonnage of low phosphorous iron is being shipped to Eastern points in the States.

Machine Tools.

The shell business continues to occupy the attention of the machinery houses, who are still busy figuring on equipments for making shells. Although no new orders for shells have been placed recently, prospective makers are preparing to do business in anticipation of obtaining contracts later. The situation as regards deliveries of new tools does not improve, and the demand for second-hand equipments is, therefore, being stimulated.

Supplies.

The demand for machine shop supplies continues good, and is likely to continue so. Tool steel is in good demand at the advanced prices. The shortage of supplies of tungsten is causing considerable concern among tool steel makers, and the situation may be said to be acute.

Metals.

There is a weak tendency throughout the metal markets, and copper, tin and lead have all declined slightly, due in the case of the two former metals to weakness in the London market. The spelter situation is unchanged, there recently having been little demand for this metal. There is a continued scarcity of aluminum and quotations are nominal. There is no change in the antimony situation, but prices are holding firm at a dull market. Solders are weaker on account of the decline in tin. Business locally is very good in metals used in munitions, while ordinary business is also improving.

Tin.—The weakness in the London market continues, and there appears to be a lack of confidence there. In New York the market is easier all round, and, except for far-off futures, buyers show no interest. The local market has declined 1c, and tin is now quoted at 45c per pound.

Copper.—The market has declined in London, and is weak and unsettled in New York. Exports from New York have fallen off during the last two or three weeks, and against this, production has been very heavy, which has resulted in the stated weakness. Copper has declined ¼c, and is quoted at 21¼c per pound.

Spelter.—The market is weaker, but dealers are not trying to force business, and prices are unchanged. The large additions to the smelting capacity now under way will increase production, but as this will no doubt be more than consumed, lower prices for spelter are hardly likely under the prevailing conditions. Local quotations are unchanged and nominal at 28c per pound.

Lead.—The market is steadier, but there is a weak tendency. The Trust are holding the price at $5.75, New York, thereby protecting that market. The local market, however, is weaker, lead being now quoted at 7¼c per pound.

Antimony.—The market is dull and unchanged, and quotations nominal at 40c per pound.

Aluminum.—The demand still holds good and supplies are scarce. Quotations are nominal at 40c per pound.

NEW WAR ORDER DEPARTMENT.

SECURING war orders is a dominant though in the mind of the Canadian manufacturer to-day. The new arrangement made by the British War Office for the purchase of supplies in Canada is, therefore, a matter of such importance that every manufacturer should understand thoroughly the basis on which the Imperial business is to be conducted from now on. With a view to securing this information **Canadian Machinery** has spent some time investigating the new system thoroughly.

At the outset it can be taken for granted that the decision of the British War Office, to make purchases of war supplies in Cañada, through the Canadian Pacific Railway, taken in conjunction with the special visit of Sir Thomas Shaugnessy to England, presumably at the request of the British Government, is an indication that the Imperial authorities are anxious to develop the facilities for war material in Canada. The appointment of Sir Thomas Shaughnessy to an office, the powers of which are indefinite, but which may be as broad as those of J. P. Morgan in the United States, and the sending out of D. A. Thomas the Welsh coal magnate as special representative of the British Department of Munitions, are evidences of the fact that the British official eye has been opened as to Canada's capacity for production. Broadly, Canada is to supply a larger share of the war supplies needed by the British Government.

The adoption of the system by which war purchases are made in Canada through the Purchasing Department of the Canadian Pacific took place some months ago. The full significance of this move did not become apparent, however, until Sir Thomas Shaughnessy was called to England. On his return, his statements indicated that he had been able to considerably extend the scope of the Purchasing Department. What special powers were granted to Sir Thomas have not been announced, but there is a general belief that they are much broader than has been officially given out. The machinery for placing orders employed by the War Office, prior to the inauguration of the new system was still in existence for the purpose of closing up the business awarded under it.

The New System.

The War Purchasing Office, as now constituted, is the development of a unit of the Purchasing Department employed by the Canadian Pacific Railway; and the internal machinery for the most part will be the same. That the C. P. R. purchasing system is efficient was demonstrated recently when the city of New York decided to model the Civic Purchasing Department on the same lines. The department has been located at 114 Windsor street, Montreal, on the Windsor street level of the Canadian Pacific Railway depot. The chief of the department is E. FitzGerald, who has been connected with the C. P. R. Purchasing Department for the past 20 odd years. Although assisted by a large and capable staff, the orders will be placed through Mr. FitzGerald, and all communications should be addressed to him.

Tentative Requisitions Supplied.

The methods employed are along the same lines as adopted in the C. P. R. The first step is when a tentative requisition is received from the War Office. This is not a definite order, but a general inquiry as to what the Department can

do in Canada to supply certain goods. Price and date of delivery are both important factors, as it is likely that in all cases there may be other sources of supply receiving competitive consideration at the War Office. Canada, as a colony of the Empire, will be entitled to some special concessions, but it cannot be expected that unreasonable allowances will be made.

The Canadian Purchasing Department, with the general information as to what the War Office needs, then goes to the Canadian manufacturers, and in some cases to jobbers, when there may not be time or opportunity for manufacture, asking for information as to what quantity could be produced and at what price. When prices and particulars are received, they are submitted to the War Office. It is not until the definite order is placed that it is known whether Canada is to get the business or not.

This, in brief, is the system which will be followed. The opinion has been expressed in many quarters that a more satisfactory method would be to make public the particulars as to the requirements of the War Office, thus giving all manufacturers a chance to apply for a share of business. This suggestion was broached by representative of **Canadian Machinery** to Mr. FitzGerald, but it was found that the Department would not consider this form of procedure. The reason for not adopting this plan is that the announcement of large requirements in any certain line would have the inevitable effect of stiffening the price of raw materials. Thus, the cost to the War Office would in the end be increased; and one principle on which the orders are now being placed is that the lowest possible cost, compatible with the essential quality and a fair profit to the maker, must be secured. It was pointed out also that from the standpoint of the Canadian manufacturer high prices were to be avoided for the reason that they would have the effect of turning the orders from Canada altogether. The system of publicly announcing the requirements would be possible if the Purchasing Department were given carte blanche as to price; an unlikely development except perhaps in emergencies.

Thus the system to be followed is as stated above. Some will disapprove of this system, but the fact remains that it is on this basis that the Department will work and the manufacturer who expects to get business must fall into line and make the best of the situation.

What Manufacturers Must Do.

The Purchasing Department claim that they have very complete information as to the manufacturers in each line. They have on file the trade papers of the Dominion and the Manufacturers' Directories published by the Department of Trade and Commerce and the Canadian Manufacturers' Association. It is the earnest object of the Department now, on receiving information of requirements, to communicate with every manufacturer in the Dominion in a position to handle some share of the business. It is in this connection that the individual responsibility of the manufacturer comes into play. Manufacturers or groups of manufacturers who consider that they are in a position to supply from present stock or to produce articles for supplies—anything that might be required by the War Office from shells to canned goods—at prices which would be satisfactory, should lose no time in getting into communication with the C. P. R. War Purchasing Department, so that there can be no question as to their complete possibilities being known to the Department. The War Office may have an accurate line on the capacity of each manufacturing plant in Canada and the stock each manufacturer is carrying at present, but no manufacturer should take this for granted. Give complete information to the Department now. Jobbers in a position to give a close price on stock lines for which there is a strong demand would also be in line for this business.

Many manufacturers have already put themselves in touch with the War Purchasing Office. All others should do so without any delay.

In this way the new system will be made efficiently operative from all standpoints.

Nor is it the intention of the Department, according to Mr. FitzGerald, to give out information concerning orders which have been placed. This, he contends, leads to dissatisfaction in some cases, and to higher quotations for future requisitions in others. This phase of the situation emphasizes still further the importance of each manufacturer keeping closely in touch with Mr. FitzGerald's department. It may be stated, however, that among the articles which have already been purchased through the new Department are: Nails, matches, miscellaneous tools, steel forges, helmets and steel wire rope. Further, it may be stated that at the present time there are a number of substantial orders in the tentative stage. Perhaps **you** are in a position to supply some of the material covered in these orders pending. Make your capacity known.

Extending Scope of Orders.

However, dealing with the requisitions as they are received from the War Office is only one phase of the word of the purchasing department. There is another, which is in a sense even more important, and that is in bringing to

A WORD TO MANUFACTURERS.

Every manufacturer in Canada who is turning out a product which classifies with any of the articles which have already been purchased for the needs of the armies of the Empire, or who believes that he is making or could make an article which could be put to such use—at a fair competitive price—should communicate with the new purchasing department established in Canada by the British War Office in conjunction with the Canadian Pacific Railway. Such information will be used whenever possible to extend the field of purchasing in the Dominion. All manufacturers who are seeking war orders should make sure that their names are on the lists of the purchasing department of the C. P. R. or the new war order branch thereof recently established.

Jobbers may also be in a position to figure on certain lines of supplies when manufacturers cannot meet the requirements readily, but it would appear to be the intention to figure prices closely.

Address,
E. FITZGERALD,
War Purchasing Department, C.P.R.,
Windsor Street, Montreal.

the attention of the Department the possibilities of Canadian industry in relation to the needs of the British forces. It is in this connection that the visit of Sir Thomas Shaughnessy to England takes special significance.

Mr. Fitzgerald is in regular communication with the War Office. Information is being constantly sent forward as to supplies which can be readily secured. Manufacturers individually must strengthen his hand in this regard.

Mr. Fitzgerald was asked as to whether any steps were being taken to secure supplies of raw material to make up orders—as, for instance, cloth for uniforms. His reply was that, so far as he knew, nothing was being done. Canadian manufacturers will have to stand on their own feet in securing raw material. It is not the intention of the Purchasing Department to assist in this respect.

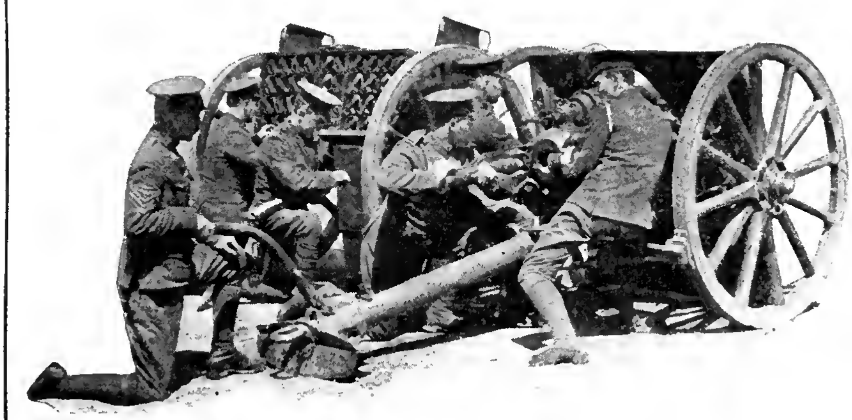
The scope of the C. P. R. War Purchasing Department in placing orders has not been clearly defined. It does not include shells—the shell situation will be dealt with in a later article—and it is officially reported not to include other munitions, but this seems likely to be altered. The Department has wider powers apparently than have yet been announced.

AMERICAN ENGINES FOR BRITISH PATROL LAUNCHES

The Sterling Engine Company, Buffalo, N.Y., manufacturer of motor boat engines, has shipped to London one 250-h.p. 8-cylinder engine, one 100-h.p. six-cylinder engine, and one 50-h.p. four-cylinder engine for motor boat control launches, and submarine destroyers for the British Government. These motor boats are to have a seagoing speed of upward of 30 miles per hour. It is stated large orders for motor engines are to follow. The company has two 300-hp. 8-cylinder engines completed and under test nearly ready for shipment. It has also an order just received for six 150-hp. 6-cylinder engines and one for four 200-h.p. motor boat engines for the Italian Government to cost $12,000.

The Turbine Equipment Co., Toronto, have sold two 750 k.w. non-condensing steam turbine-driven alternators to the Aetna Explosives Co., Montreal, Que.

M. Beatty & Sons, Ltd., Welland, Ont., announce that the control and management of the company has been changed. H. L. Beatty has been elected president, and A. O. Beatty, vice-president and general manager. Harris T. Dunbar, of Buffalo, has been elected a member of the board of directors. V. R. Browning, B. F. Miles, directors, and R. A. Greene, general manager, who have had charge of the business for the past three years, have severed their connection with the company.



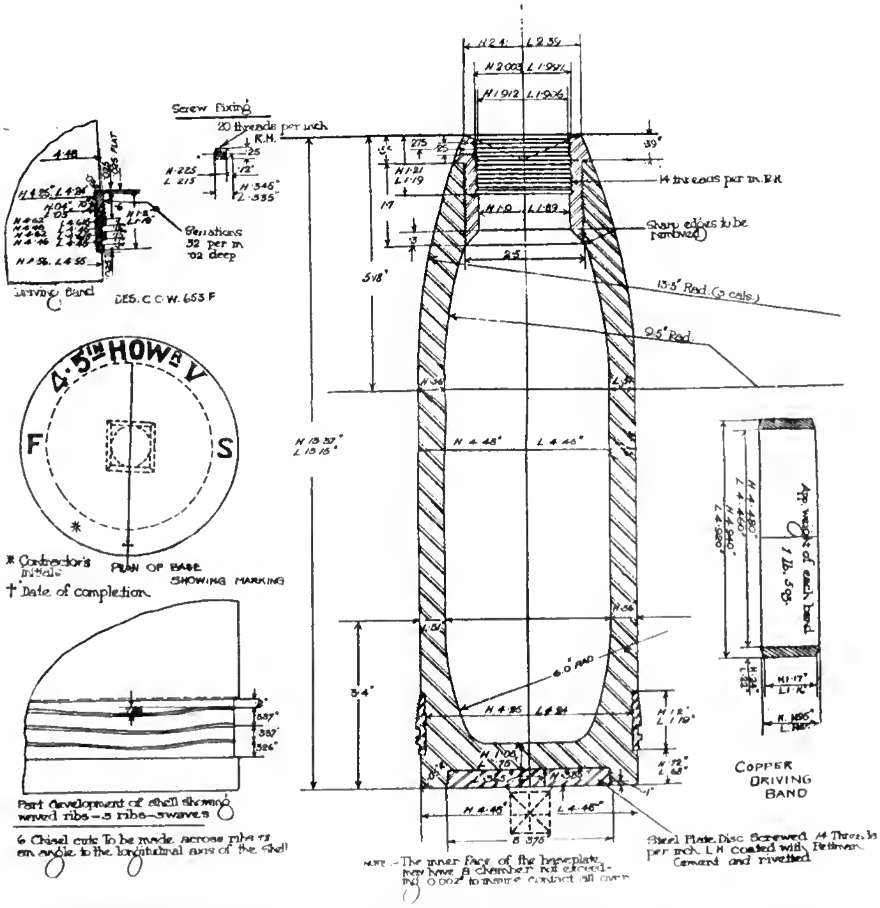
Machining 4.5 H.E. Shells in a Steel Foundry Plant

Staff Article

The sudden call from the manufacture of articles of a peaceful commerce to that of supplying the gods of war with provender of a prodigious amount and such as we never dreamed of producing, has been met by the administrations of our iron and steel industries in a manner that demands whole-hearted admiration for their enterprise, capacity, resourcefulness.

THE forging for a 4.5 howitzer shell is very similar in appearance to that of the 18-pdr. shrapnel, except that it is, of course, of larger dimensions, and being a high explosive shell, the walls are thicker than for shrapnel. As regards the machining operations, the procedure adopted comprices methods used for both the 18-pdr. shrapnel and high explosive shells. The forging being hollow, calls for methods which follow closely along the lines adopted for shrapnel, whereas the later operations conform more to those adopted for the 18-pdr. high explosive, in the matter of the base recess, varnishing, baking, etc. In comparison with shrapnel, a noteworthy exception is the elimination of the heat treatment, this process not being necessary for the various types of high explosive shells. The operation involving the closing in of the shell nose is, however, common to both types, as are also the grooving, waving, copper-band pressing and turning operations.

Notwithstanding the apparent similarity in the operations, as indicated above, the extra size and weight of the 4.5 shell calls for larger and stronger tooling fixtures and in some cases heavier machines. It therefore follows that, in making larger calibre shells, new problems confront even those who may have been successfully making the smaller calibre shells. In the solution of these problems and in overcoming the difficulties encounterered, the prospective manufacturer of 4.5 shells is specially interested. Taken as a whole, the machining of these shells is at present in a more or less experimental stage, but at the plant under review, which, by the way, was one of the first to undertake the manufacture of 4.5 shells, these problems have been surmounted successfully, although in some operations improvements are contemplated with a view to increasing production. In the main, however, the operations to be described later may be said to be of a permanent character.

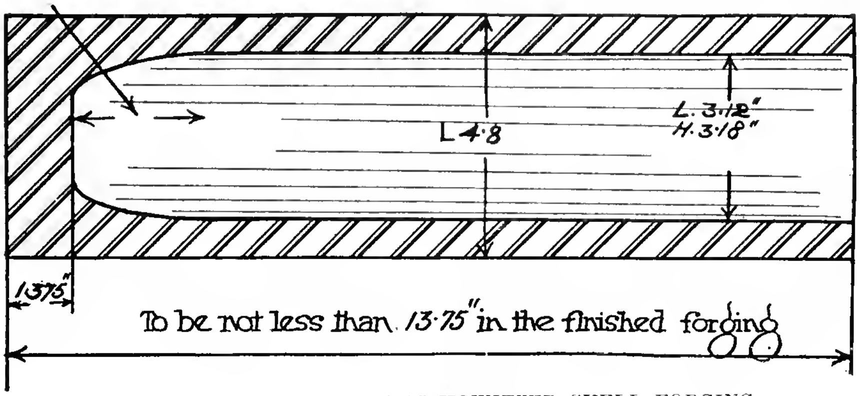


Q.F. HIGH EXPLOSIVE 4.5 INCH HOWITZER SHELL, MARK V/L/, FORMED FROM STEEL BILLET 4.8 INS. DIA. BY 9½ INS. LONG AND WEIGHING 49 LBS. WEIGHT OF FILLED SHELL 35 LBS. PLUS OR MINUS 9 DRS. WEIGHT OF BURSTING CHARGE (TROTYL), 4 LBS.

In the manufacture of the 4.5 shells great care has to be exercised in keeping the weight within the prescribed limits. The feature is, of course, common to shells of smaller calibre, but none the less important for the larger shells. The walls also be of uniform thickness and the shell perfectly concentric. To obtain this concentricity, the shell has a centre drilled in the base, which is retained as long as possible and in all operations involving the removal of metal, the shell revolves in this centre.

An important point to watch is during the nosing operation. After the nose has been heated and closed in, the shell must be put in a place, preferably a steel box, away from any cold draft and allowed to cool

slowly. This avoids the possibility of the shell, which is of 45 to 50 carbon, from hardening at the nose. It is also essential that the threads in the nose should be absolutely accurate; the same remark applies to the base plate or plug. There are only a few threads in the base, but the plug must bottom in the recess, and at the same time be a very tight fit. The reason for recessing the base is, of course, the same as for the 18-pdr. high explosive, to enable the inspector to detect any flaw or "pipe" in the metal at the base, and thus avoid any possible explosion when firing.



Q. F. HIGH EXPLOSIVE 4.5 HOWITZER SHELL FORGING.

Accurate gauging is, of course, of the greatest importance, and high and low gauges are used at practically every operation. With regard to obtaining the necessary weight, a system is followed of keeping the shell overweight until the body is turned to the finished size, the extra metal being left on the base and removed to obtain the required weight. The operations involved in this will be described later.

The Forging Feature.

As already stated, the 4.5 howitzer shell is made from a hollow steel forging and not from a solid rolled steel bar, as in the case of the 18-pdr. high explosive shell. The forging is made from a billet or blank 9½ in. long by 4.8 in. diameter and weighing 49 pounds. The ingot from which the blank is obtained is made of cast steel, two blanks being cut from each ingot. After forging, the shell case is 4.8 inches outside diameter and not less than 13¾ in. long over all, the weight, of course, not being a fixed quantity on account of the ragged ends and consequent variation in length.

The finished shell when ready for shipment weighs 27 lbs. 14 ozs., exclusive of the nose cap and explosive charge, while the weight, when ready for service, is 35 lbs., which includes 4 lbs. for the bursting charge. The shell weighs 24 lbs. after the varnishing operation, exclusive of the base plate and nose socket. The over-all length of the shell finished, but without the socket is 12.71 inches. The inside finished diameter of the straight part of the case is 3.406 inches and the outside is 4.46 inches. The base is 15/16 in. thick finished.

Cutting Off Ends..

After the cases have been received from the forge, the first thing to be done is to square up the open end and cut off the superfluous metal. At this plant an axle lathe, made by the Bridgeford Machine Tool Works, Rochester, N.Y., is used for this operation. The illustration shows the drive gear housing in the centre of the lathe and the drive plate, on both sides to which are fastened special clamps for holding the shells. The tool holders are in front on the cross slide. This machine is motor-driven, the motor being located at one end of the bed to the left hand. Before the shells are put in this machine they are marked off on a bench, so that the operator knows how much metal to remove.

Facing Up Base and Centering.

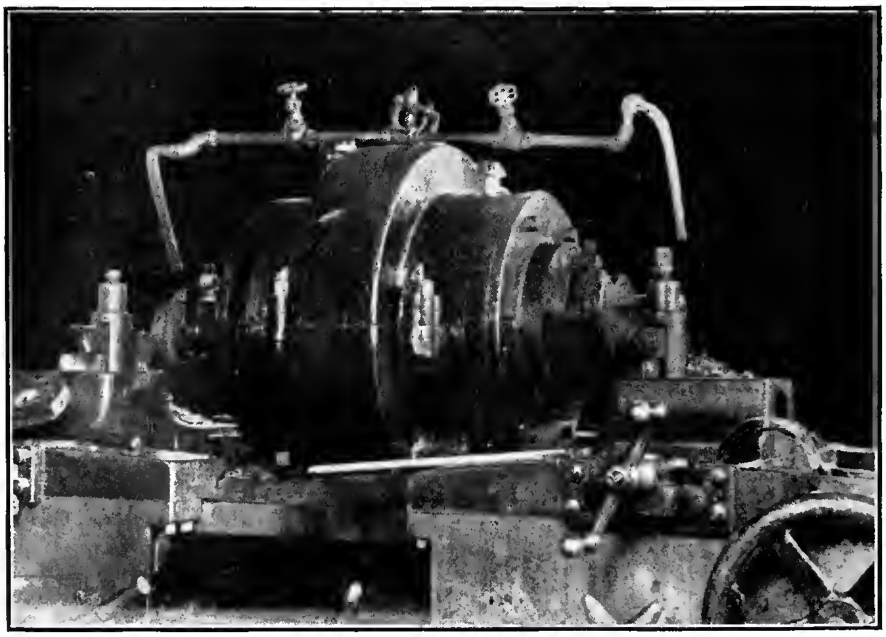
Previous to drilling the centre in the base, the shells are taken to a Bertram planing machine for the bases to be cleaned up. On either side of the table are two long castings with a series of grooves to take the shell cases. The castings are held securely in position by knee brackets bolted to the planer table. The cases are held by clamps, two cases to a clamp bolted to the casting. The planer is equipped with two tools, and a roughing cut only is taken off, sufficient metal being left to permit weight adjustment at a later stage.

To keep the shell cases as concentric as possible during the subsequent machining operations, a centre is drilled in the base. This centreing is done on an engine lathe, the shell being held on a taper mandril while a countersunk drill is performing the centreing operation.

Rough Turning.

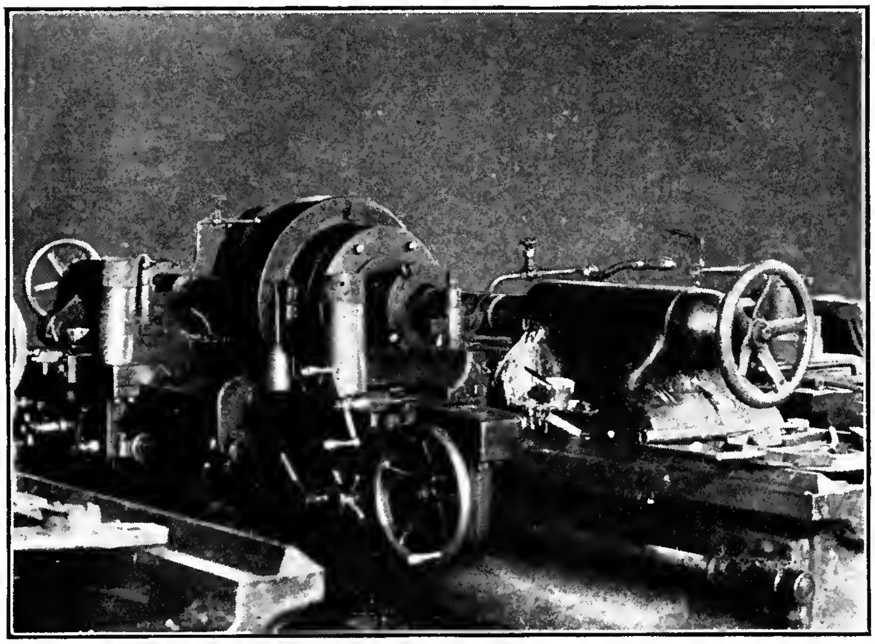
The rough turning operation is performed on a "Bridgeford" axle lathe of the same type as issued for cutting off the shell ends. To each drive plate is attached a self-centreing chuck with a taper stop in the centre for engaging with the open end of the shell. At the face of the chuck outside is a driving ring with four set screws which are tightened up on the shell. The base centre revolves on the tailstock centre. An ordinary turning tool is used and one roughing cut is made. The shell lying on the lathe in the illustration shows how far the machining is carried at this operation, which is equivalent to the length of the straight part.

After rough turning, the base of the shell inside is spot drilled in order to



CUTTING OFF OPEN END OF SHELL CASING ON AN AXLE LATHE.

relieve the cutter when boring at the next operation. A "Bertram" two-spindle drill is used for this work, each shell being held securely in a box chuck or vise fastened to the drill table.



ROUGH TURNING SHELL CASING ON A "BRIDGEFORD" AXLE LATHE.

Inside Boring and Inside Bevel.

The work done at this operation consists of roughing and finishing boring inside the shell case, forming the base inside to the correct shape and forming inside bevel at the nose. The machine used for this operation is a Warner & Swasey turret lathe equipped with a self-centreing chuck and steady rest to support the chuck owing to the long overhang.

The first turret face holds a boring bar with a cutter at the end for boring out the inside for a short distance to give the next tool a better start. The second turret face holds a four lip hogging cutter for roughing out inside. The third turret face has a boring bar with cutter which makes another cut inside and also forms the base inside. The profile of base will be seen in cross section of the shell on another page. The fourth turret face makes the finishing cut inside the shell and also finishes the profile inside of base. The fifth turret face holds a taper cutter for boring the inside bevel to the nose. This inside bevel and the outside bevel also, are formed so that after the nose has been closed in, it is the required shape and size.

Outside Bevel and Facing Base.

Immediately following the operation described above, the shell is taken to an engine lathe to have the outside bevel formed which finishes the preparation of the nose for the closing-in operation. Two engine lathes supplied by the R. McDougal Co., Galt, Ont., are installed for this purpose. Each lathe is equipped with a self-centreing chuck supported by a steady rest attached to the lathe bed. An ordinary turning tool is used. The bevel is $1\frac{3}{4}$ ins. long and begins $1\frac{1}{2}$ inches from the nose. The accompanying sketch shows the inside and outside bevels and their relation to the nose after closing.

Before being taken to the bulldozer for the nosing operation, the base of shell is faced up on an engine lathe supplied by the American Tool Works Co., Cincinnati, Ohio. The shell is held on an expanding mandril which has a bar in the centre and projection at the end, working against three grips at the front and back of the mandril. When the shell is placed on the mandril it is forced up against the chuck, the inside of the base engages with the bar in the mandril and thus forcing out the grips and holding the shell tight. A roughing cut is taken off the base by an ordinary tool, after which the shell is ready for the nosing operation.

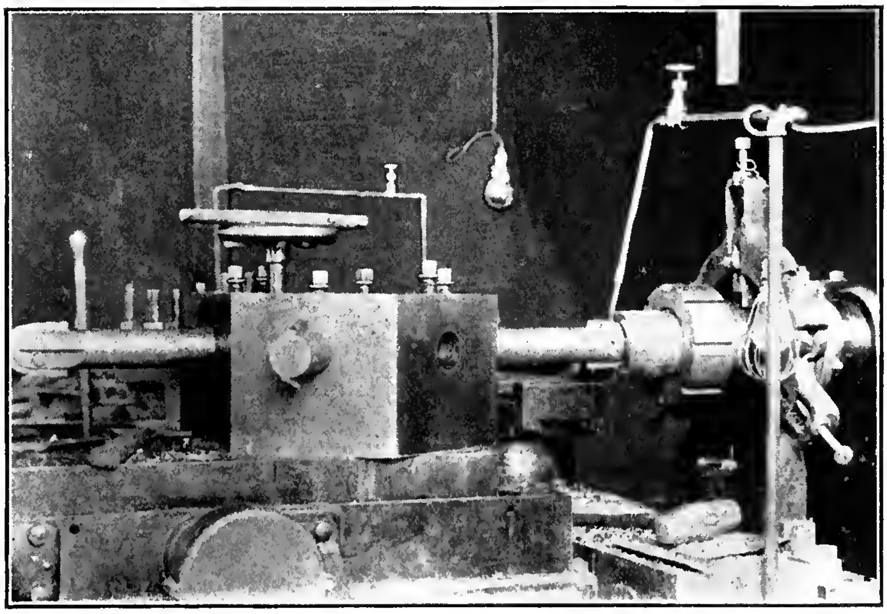
Closing-in of Nose.

The accompanying illustration shows clearly the general feature of the bulldozer used for this operation, and shells resting on the press show the shape of the nose before and after treatment. In the centre of the ram will be seen the die which is conical inside and has a water jacket outside supplied with water through the pipe above. The shell is supported horizontally on a bracket, not seen in the illustration, fastened to the long casting in the foreground.

The nose only of the shell is heated in the oil-fired furnace located on the right. Care is taken that only a certain length of shell is heated, otherwise it might break down in the press. When heated to the required degree, the shell is taken out of the furnace, placed in the bulldozer, the ram of which advances and closes in the nose. The shell is afterwards taken out and placed in a steel box so that it may cool gradually to avoid all possibility of the nose hardening.

Centreing Base.

Before the shell is ready to have the nose finished, a centre is drilled in the base on a drill press supplied by W. F. & J. Barnes, Rockford, Ill. The shell is held in a vise base end up, and a jig is placed over the end to ensure the centre being drilled in the correct place. The



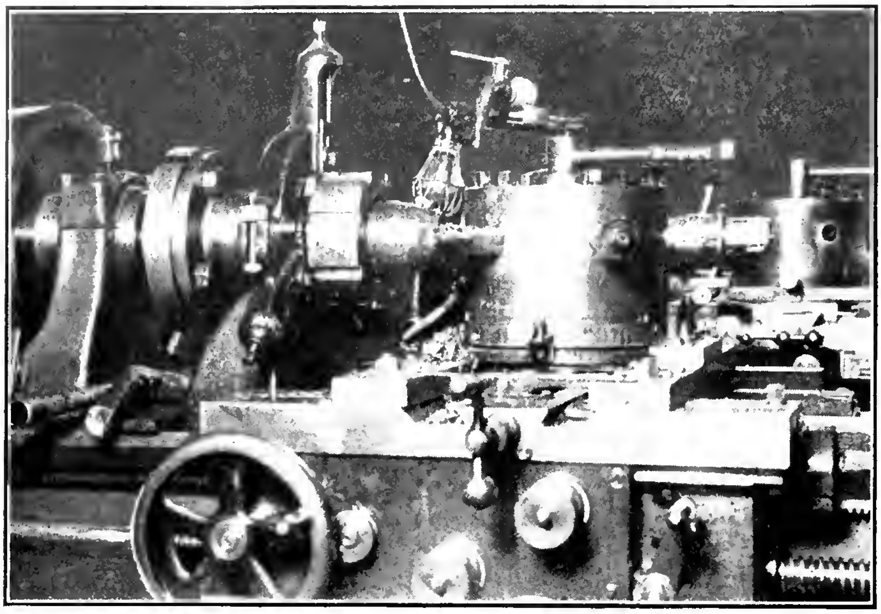
ROUGH AND FINISH BORING INSIDE OF SHELL AND FORMING INSIDE BEVEL.

inside of the nose is now ready to be finished off.

Finishing and Threading Nose.

For this operation one "Walcott" engine lathe equipped with a turret, and two turret lathes supplied by Schumacher & Boye, Cincinnati, Ohio, are installed. All these machines are tooled up in the same manner and are equipped with self-centering chucks supported by steady rests fastened to the lathe bed. The first turret face holds a bar for locating the shell in the correct position in relation to the tools. The bar has a small cutter at the base for cutting the shell to lengths, being gauged from inside base. The second turret face holds a bar with cutter for roughing inside the nose. The next is a bevelling tool for cleaning up that part of the nose inside and beyond the part to be threaded.

The fourth tool is a reamer for finishing the nose previous to threading which is done by a "Murchey" collapsible tap held in the fifth turret face. The shell is now finished inside and is taken to a bench where a pug centre is screwed in the nose to hold the shell in the lathe at the next operation.

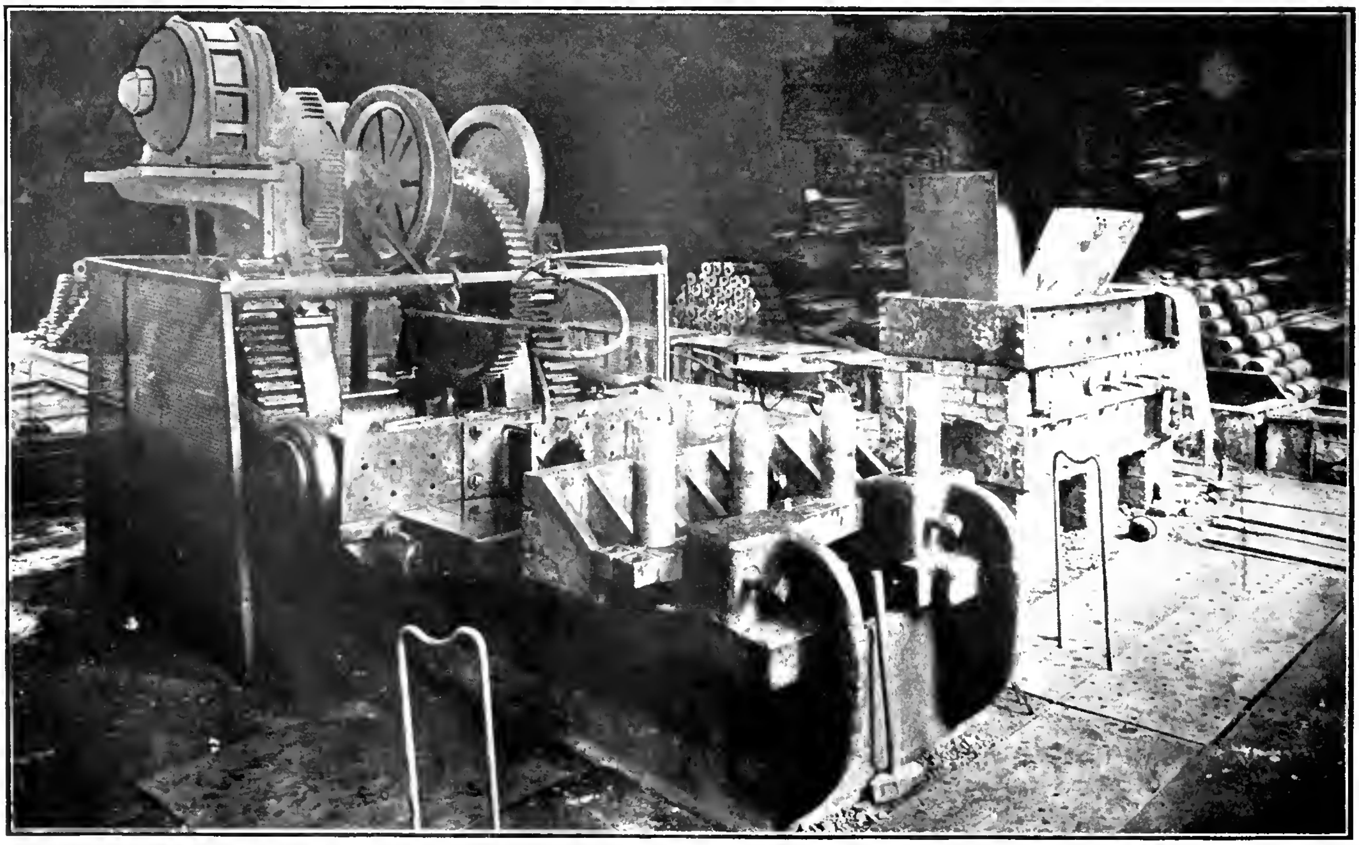


FINISHING INSIDE OF SHELL NOSE AND THREADING SAME.

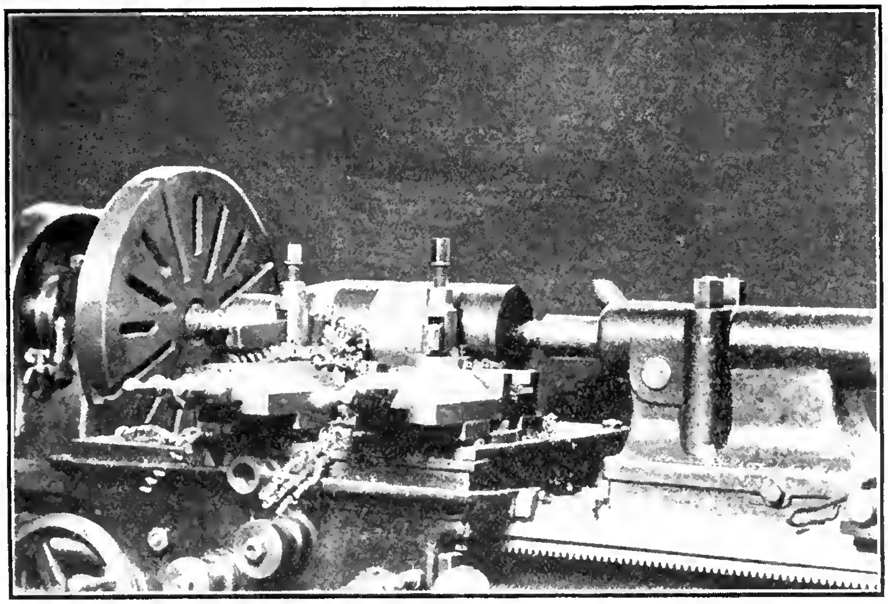
Finish Turning Body.

Five engine lathes built by the R. McDougall Co., Galt, Ont., are installed for finishing the outside of the shell. One of the lathes is equipped with two cross slides and tool holders as shown in the illustration. This arrangement enables two cuts to be taken at a time, thereby increasing production. The other four lathes have only one tool and slide, but are the same in all other respects. The base of the left hand cross slide projects at the back and engages with a cam on a bar fastened to the lathe bed at the back. There is also a weight hanging over at the back, connected to a cross slide to hold the slide bar up to the cam, and so give the correct profile to the nose when the tool is cutting.

In the machine illustrated, the left hand tool turns the nose only and the right hand the straight part only. One tool starts at the nose, and the other at the shoulder, both travelling toward the base. The lathe with only one tool makes but one cut which starts at the nose and finishes at the base. The cam attachment at the back takes care of the nose profile, the same as in the other lathe described. The shell is revolved by a bracket bolted to the face



CLOSING-IN SHELL NOSES ON A BULLDOZER. OIL-FIRED NOSE HEATING FURNACE AT THE RIGHT.



FINISH TURNING OUTSIDE OF SHELL.

plate and engaging with the square end of the nose plug centre.

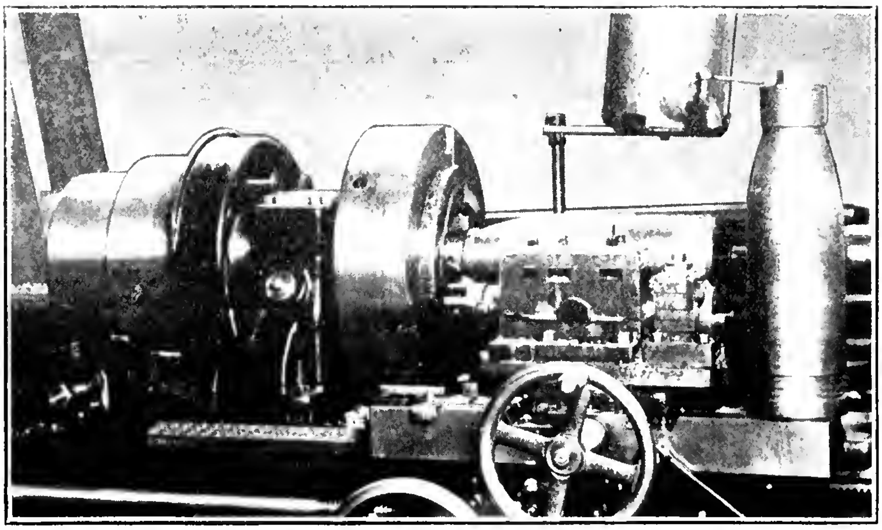
Weight Adjustment.

On the completion of the above operation, the nose plugs are taken out and the shells weighed and inspected. During all preceding operations the shells have purposely been kept overweight in order to be on the safe side, it being easy of course to remove metal but impossible to add any. This extra weight is left on the base and is removed after the amount has been determined by the inspector who weighs and marks each shell before it is taken to the lathe.

For facing the base to weight, an "American" engine lathe equipped with a universal chuck is installed, and also a "Gardner" engine lathe. This is a plain job and does not call for particular mention. The centre at base has by this time been considerably reduced and so requires making larger. This operation is performed in an engine lathe built by the Bradford Machine Tool Co., Cincinnati, Ohio. The shell is held in a self-centreing chuck supported by a steady rest. The shells are next weighed and inspected, and the nose plugs screwed in again.

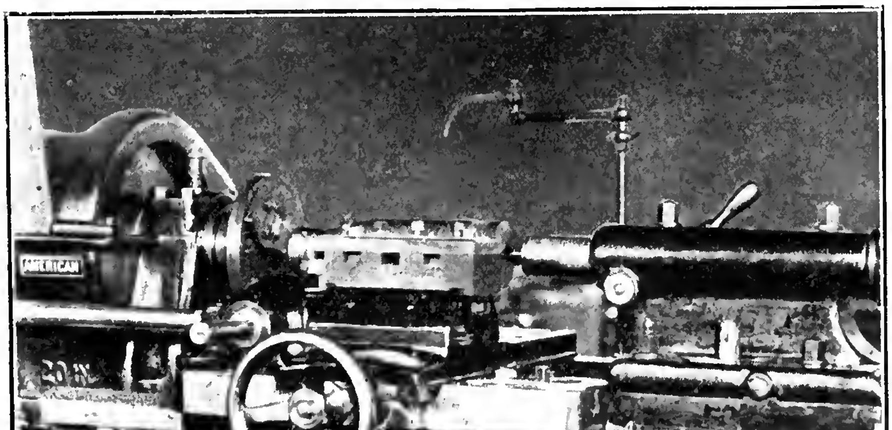
Grooving Undercutting and Waving.

It will be noticed from the illustrations that two methods are employed for machining the driving band recess. The principal difference between the two types of machine installed is in the method of oscillating the tool holder when forming the wave lines. In both cases the sequence of operations is the same and the cutting tools are arranged in the same order, viz., grooving, undercutting and waving. The difference is in the latter operation, a cam being used in one case and an arrangement of shafts and gears in the other machine. Both will be dealt with in detail. The machine installed for performing this work consists of a 20-in. engine lathe built by the American Tool Works, Cincinnati, Ohio, two engine lathes by the Canada Machinery Corporation, Galt, Ont., and one engine lathe by R. Gardner & Sons, Montreal, Que. The "American" lathe is equipped with the special waving gear and the other lathes have a cam, attached to the chuck.



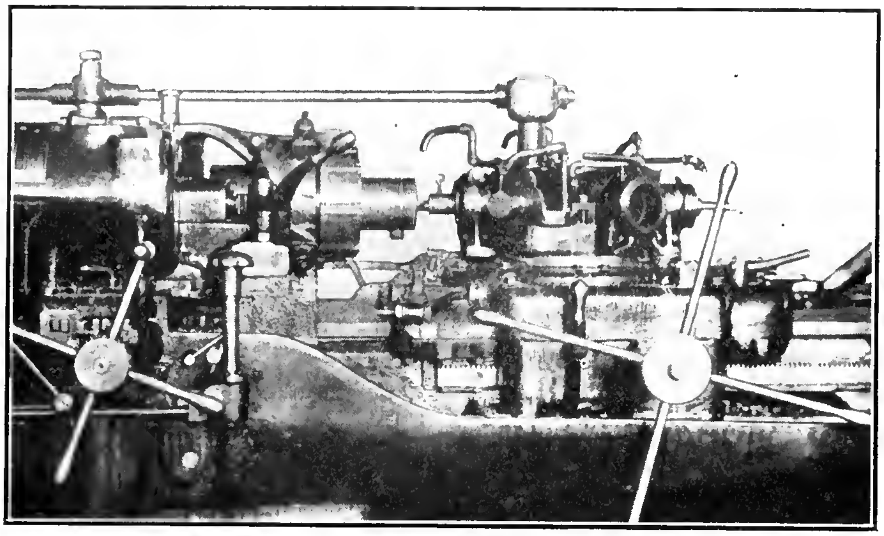
GROOVING, UNDERCUTTING AND WAVING FOR COPPER BAND ON A C.M.C. LATHE.

The illustration shows the general arrangement of the "American" lathe which will be described first. A plug centre has already been screwed into the nose, the square end of which engages with an attachement bolted to the lathe face-plate, thus revolving the shell. The tailstock centre engages with the centre at the base of shell. The location of the groove from the



GROOVING, UNDERCUTTING AND WAVING FOR COPPER BAND ON AN "AMERICAN" LATHE.

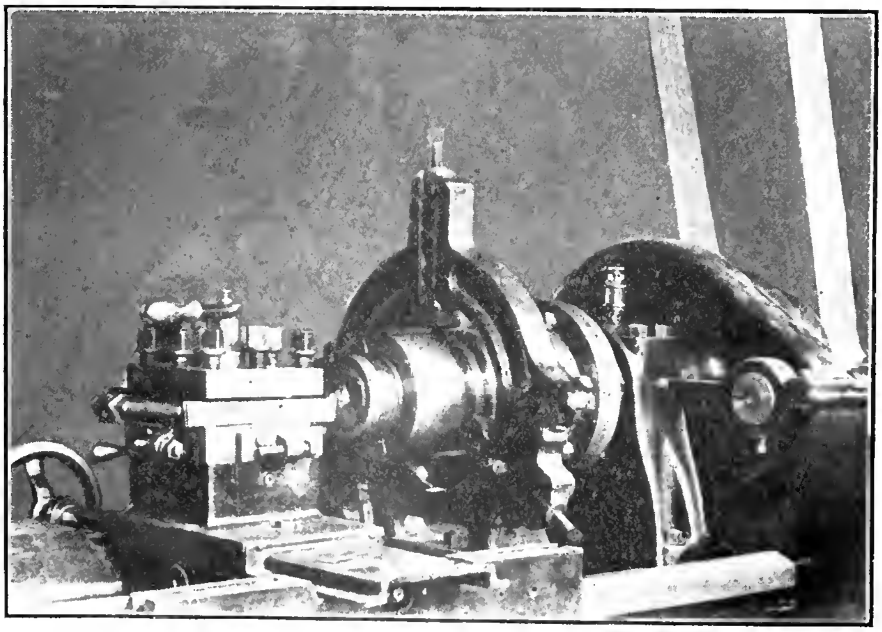
base is determined by means of a suitable gauge. The lathe saddle is moved along until the left hand or grooving tool is in position. The operator then moves the cross slide inwards, thus cutting the groove. The saddle is next moved back until the middle or undercutting tool is in position.



RECESSING AND THREADING SHELL BASE ON A JONES & LAMSON FLAT TURRET LATHE.

This tool has two small cutters projecting outwards diagonally at the same angle as is required for the undercut. When cutting, the saddle is moved along slightly one way until the shoulder of the cutter is up against the edge of outside of the groove, the same method being followed for the other side. The undercutting being completed, the tool is withdrawn and the saddle moved along until the right hand or waving tool is in position. The tool holder for this operation is oscillated by means of the shaft and gears located on the left hand of the cross slide. The shaft is driven by gears in a gear box located at the extreme left of the headstock, and can be put in or out of gear by a lever at the will of the operator. It may here be remarked that this arrangement is only used during the waving operation, and also that the shafts have long keyways and can therefore slide in or out without interfering with the motion of the saddle or cross slide. Three wave lines are cut as against two for the smaller shells.

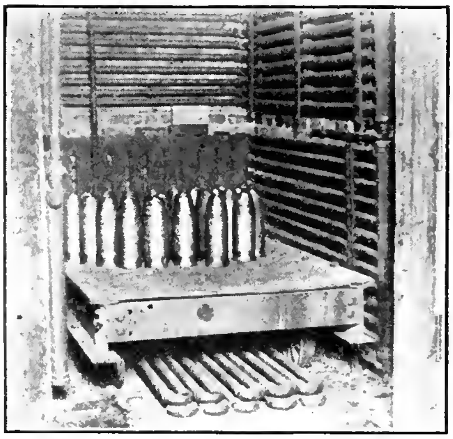
The tooling fixture on the Canada Machinery Corporation lathes, which was designed and constructed by the Canadian Steel Foundries, Ltd., has all the cutting tools at the front, but the waving attachment is separate, and the usual cam being employed for oscillating the waving tool. The shell has the same plug centre but is held in a universal chuck equipped with a three point cam. The method of operation as regards to the grooving and undercutting is the same as for the "American" lathe. The same shaped cutting tools are used and in the same order, it will therefore be unnecessary to describe them again. The illustration shows the wide box tool holder with the tools in the left and right hand slots. The smaller holder to the right hand holds the waving tool which is shown in operation. The saddle is locked and the roller in the round bar running through the larger tool holder is pressed up against the cam which transmits the oscillating motion to the tool; a strong spring under the bar keeps the roller against the cam. The depth of cut is regulated in all cases according to an index on the hand wheel, this being checked by gauges.



ROLLING BASE PLUG AND FACING-UP SHELL BASE.

Base Recess.

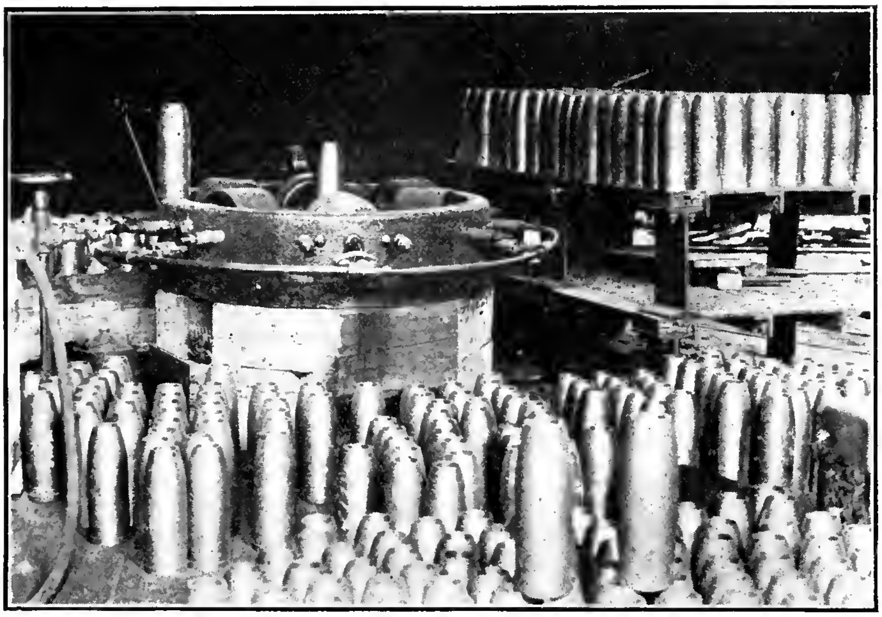
At the next operation, the base is formed and threaded. A battery of six "Hartness" flat turret lathes built by the Jones & Lamson Machine Co., Springfield, Vt., are installed for this work. The ordinary chuck was too light for the work so the machines were equipped with special self-centreing chucks, and, on account of their long overhang, a support in the form of a bracket was devised. The top part of the bracket is fastened to the lathe head, while the lower part rests on and is bolted to the lathe bed. This arrangement holds the chuck steady and prevents vibration. Before the shell is chucked, the plug centre is taken out. In the centre of the chuck is a mandril with a spring at the end. This spring has a tendency to force the shell out while it is being placed into position in the chuck by a swinging arm on the front part of turret. By means of this arrangement the shell is located in the correct position in the machine. The arm when not in use lies flat on the turret bed.



VARNISH BAKING OVEN.

The first tool is a flat drill which is used for obtaining sufficient clearance for the roughing cutter which is held in the second turret and which roughs out the base and sides. In the third turret face is a cutter of similar design to the preceding one, this being used for finishing the bottom of base and side, preparing the latter for the threads. The fourth tool is a cutter for finishing the recesses in the base for the threads to start and finish in. The fifth tool is a chaser for cutting the threads. This is a somewhat delicate operation and requires considerable care. The chasing tool is operated by a special attachment for giving the threads the desired pitch of 14 threads per inch. The lead screw is behind the turret face and the gear box is shown above the turret in the illustration connected to a shaft from the lathe head. The threads in the base are left hand.

The machine head of the lathe is traversed by hand for diameter feeds. A series of bar stops under the head are used for cross or diameter feeds, each stop being set in conjunction with its corresponding turret tool. A similar arrangement of stops is used under the turret for longitudinal feeds.



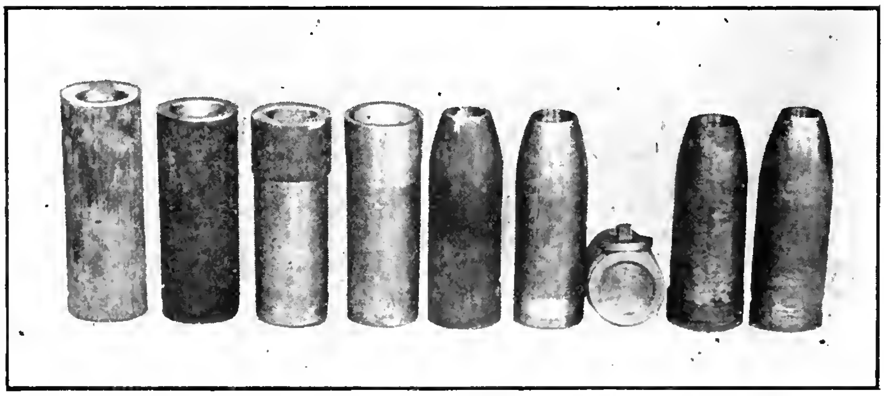
CANADIAN STEEL FOUNDRIES COPPER BAND PRESS.

Inspection, Etc.

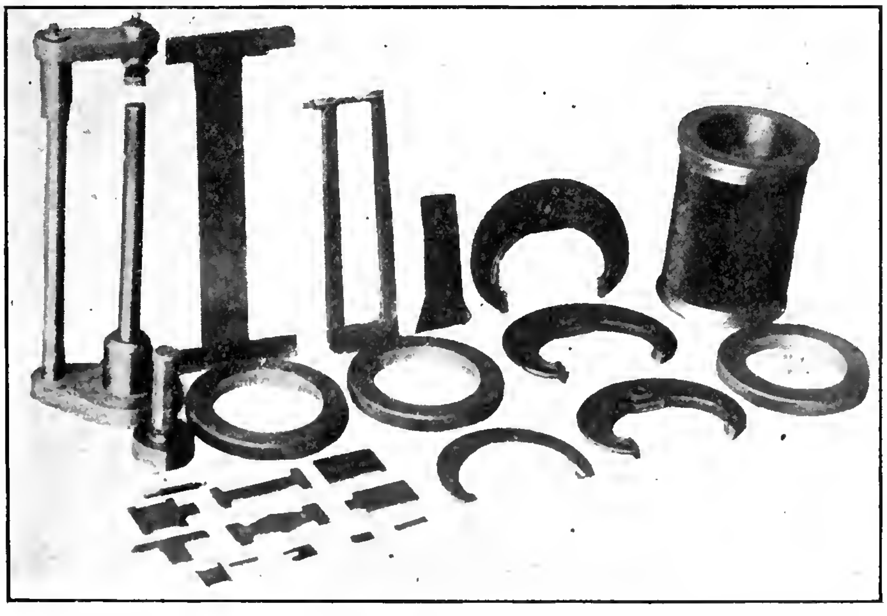
A number of minor operations now follow, the most important being the inspection. The shells are carefully gauged and inspected and then taken to the sand blast where the inside is cleaned and prepared for the varnishing process. The wave lines are next nicked with a cold chisel after which the nose and base recess threads are hand tapped. The shells are then subjected to the preliminary government inspection, the marking being stamped on and the shells arranged in batches of thirty.

Finishing Base.

The plate which is screwed into the base recess is a steel drop forging similar to that used for the 18 pdr., H. E. shell, only of course larger. The base plate is turned on an engine lathe equipped with a special expanding chuck for holding the square head of the plate. The lathe has a turret holding three tools. The first turns the inside diameter in two cuts, the second being the finishing cut for the threads. The second tool forms the camber on the face of the plate, two cuts being made for this. The third turret face holds a tool for cutting the threads on the base plate.



THE 4.5 HIGH EXPLOSIVE SHELL IN ITS VARIOUS STAGES OF MANUFACTURE FROM THE FORGING TO THE FINISHED PRODUCT.



GAUGES USED IN THE MACHINING OF 4.5 HIGH EXPLOSIVE SHELLS.

Before the base plates are screwed into the base recess, the threads are covered with "Pettman's" cement. The shell is held securely in a bench vise and the plate screwed in by means of a wrench. Before being taken out of the vise the square head on the base plate is wrenched off.

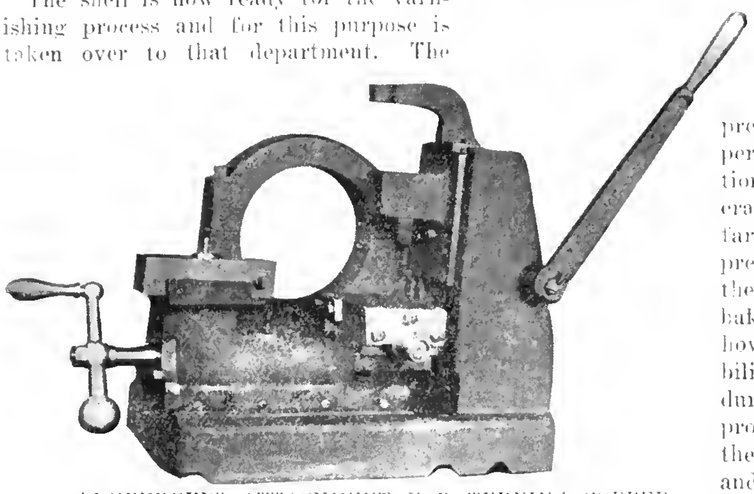
The base is finished on an "American" engine lathe equipped with an expanding chuck and draw-back mechanism. The chuck is supported by a steady rest as shown in the illustration. The tool holder contains three tools—two cutting tools and a rolling tool. The base plate, which projects slightly

when in the shell, is first rough machined, and then faced up by the second tool flush with the base of shell proper. The joint between the base plate and base is now closed by the rolling tool after which the entire base is faced up and finished.

Varnishing and Baking.

The shell is now ready for the varnishing process and for this purpose is taken over to that department. The varnish it will be remembered protects the inside of the shell from the corroding effect of the explosive. A hollow brass plug is first screwed into the shell nose to keep the varnish from the threads. The shell is filled with varnish which is immediately poured out and the shell placed on a draining rack, leaving only a thin film of varnish all over the inside.

For the purpose of hardening the varnish, the shells are placed in an oven for 8 hours at a temperature of 300 degrees Fahr. As will be seen from the illustration, the oven is built of brick with wooden doors, insulated with asbestos to prevent radiation. The oven is steam heated and contains steam pipes all around the walls and on the floor. The truck shown in the oven is only a temporary arrangement, as it is proposed to have a truck capable of holding three tiers of shells, which will fill the oven. It will be noted that the baking has preceded the copper band operations. The general practice so far has been to press the band on the shell before baking. There is, however, a possibility of the heat during the baking process expanding the copper band and thus loosening it. This point, however, has not been definitely settled, and as far as equipment is concerned, it is immaterial which operation is performed first.



"LYMBURNER" ATTACHMENT FOR TURNING COPPER BAND.

Copper Band Press.

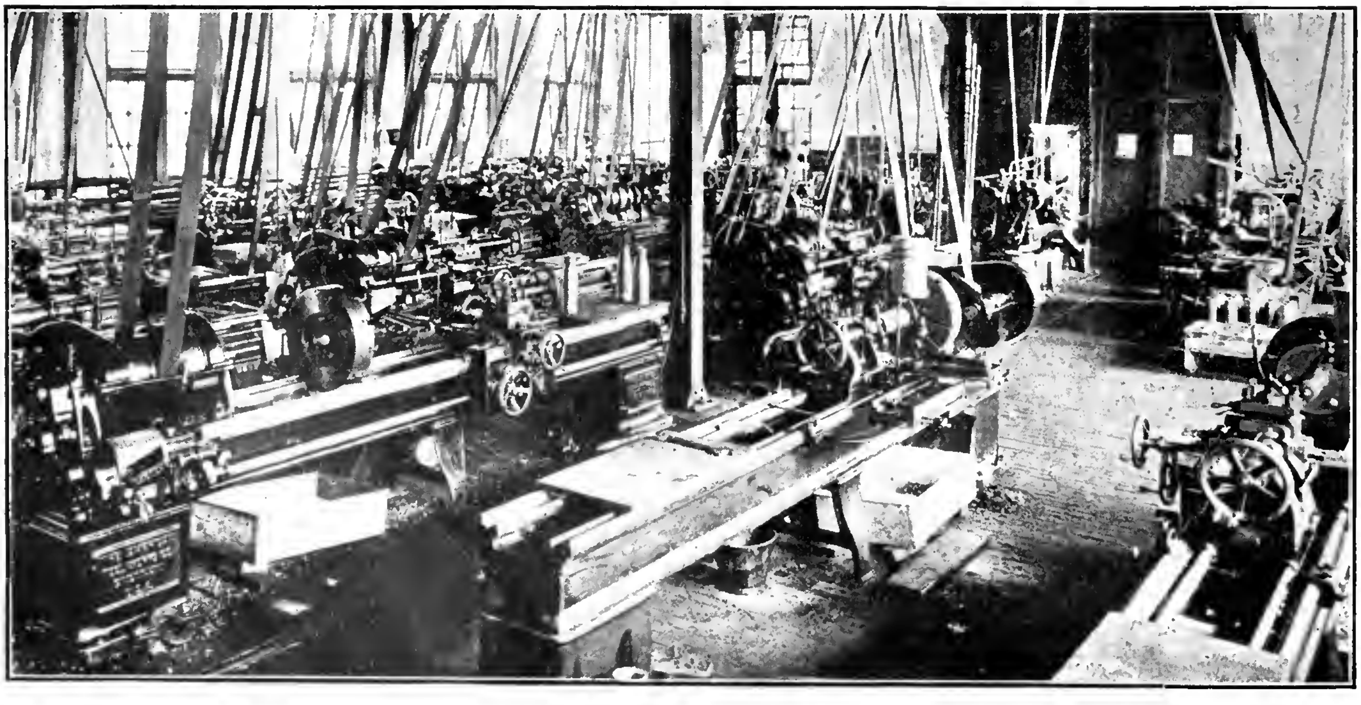
The hydraulic press for pressing on the copper driving band was built by the Canadian Steel Foundries, Ltd., Montreal, Que., and generally speaking it is very similar in design to some other presses on the market, although not quite so high off the floor, an advantage when handling heavy shells. The press has six cylinders which converge towards the centre. The shell with the rough copper band on is placed on the plate in the centre of the press, and the power applied. The pressure is then released the shell given a slight turn and power applied again thus equalizing the pressure on the band. The cylinders are returned to their original position by springs shown outside the press frame.

An engine lathe equipped with a "Lymburner" attachment for turning copper bands is used for finishing the driving band. The attachment is fastened to the lathe bed and has a cross slide in front for the roughing tool and bracket at the back with a vertical slide for holding the finishing tool. The front cutting tool is brought into operation first and the roughing cut made. The back tool is operated by a lever and passes down behind. It is set so that in passing it removes or shaves off the necessary quantity of metal. The cutting tools are of special form to cut the driving band to the required form and also the serrations which are 32 per inch.

Final Operation.

The shell is now complete with the exception of the brass socket. The hollow plug has been taken out and the brass socket screwed in the nose. These sockets are practically finished when they are received at the plant, and the only machining to be done after being put in the shell is to turn the outside of the socket to conform to the profile of the shell nose. The work is done on an engine lathe.

Between the various operations where it has been necessary to move the shells



GENERAL VIEW OF MACHINE SHOP, SHOWING SHELLS IN PROCESS OF MANUFACTURE.

any distance, they have been moved in boxes holding lots of thirty. These boxes are raised off the ground to allow of their being moved by the "Chapman" elevating and transveying trucks, several of which are in use at this plant.

The shells now undergo the final government inspection, and are carefully weighed and gauged, one of each series being selected for the firing test. They are then painted, dried and packed for shipment.

POST BELLUM COMPETITION.

AFTER the war, competition with Germany is to be more severe than before, and it is imperative for American manufacturers to cut their costs to the bone, and do it in a hurry. Such is the view expressed in a recent address by Robert Grimshaw, consulting engineer and lecturer in New York University, who, although an American citizen, lived many years in Germany. He has come from that country within a year, and is thoroughly familiar with conditions in Germany and the United States.

Mr. Grimshaw says that after the war there will be in Germany alone at least two million men who will return home and find that they have no jobs. Some of them will see that factories where they worked before the war have been closed, and some of them will discover that their jobs have been filled by women and children. Mr. Grimshaw believes that these men will be put to work at about 50 cents a day, and that the product of their hands is going to be dumped upon this and other countries. He also says that there is a large class of work being done now in Germany, but the product cannot be shipped on account of war conditions. He believes that as soon as peace is declared and ships are free to travel without being molested, this product of the war period will also be dumped in the United States and other countries now at peace.

These are statements worthy of the most careful consideration by everyone who has at heart the welfare of our work people. In discussing the question as to what is to be done about it, Mr. Grimshaw says that the tariff is usually made by people who do not know anything about it, or else by those who know too much about it and consult their own interests instead of those of the general public.

There is a great deal of truth in this statement, and it is high time to begin a scientific investigation to determine as nearly as possible what kind of a tariff bill should be enacted. This should be done by a non-partisan commission, and done thoroughly. Then when the war ends, we shall have at hand a mass of facts of great value as a guide in quickly passing a tariff bill, if a revised tariff is not placed upon the statute books before peace is declared.—Iron Trade Review.

NEW FACTORY INSPECTION REGULATIONS.

THE twenty-seventh annual report of the Factories Inspection Branch of the Ontario Department of Agriculture has been issued. It shows that 10,059 inspections of factories and shops were made during the year in 410 cities, towns and villages. The number of accidents reported are 1,270 of which 52 were fatal.

Regulations regarding specifications for fire escapes are given with illustrations, together with a most practical article on how to lessen fire dangers. There are also helpful suggestions regarding ventilation and general sanitation, guarding of machinery, child labor, seats for females in shops, and wearing of girls' hair in mills and factories. Results are also given of the inspection of bake shops, canning factories and evaporators. Special emphasis is placed upon eye protection in certain occupations. In fact "safety first" is urged upon every possible occasion. A most suggestive feature of the report is a series of danger signs in which warnings are given in nearly every foreign language.

Bright Whitewash.—Half a bushel unslaked lime; slake with warm water, cover it during the process to keep the steam; strain the liquid through a fine sieve or strainer; add a peck of salt, the same to be previously well dissolved in warm water; add 3 lb. of ground rice boiled to a thin paste, and stir in boiling hot; add ½ lb. of glue which has been previously dissolved over a slow fire, and add five gallons of hot water to the mixture; stir well, and let it stand for a few days, covering up to keep out dirt. It should be put on hot. One pint of the mixture, properly applied, will cover a square yard. Small brushes are best.

The Design and Constructional Features of Plug Gauges--I.

By C. Hattenberger

The application and maintenance of proper plug gauges for certain lines of manufacture mean greater efficiency and interchangeability. Where a large number of similar pieces are required, suitable gauges are most essential, and should be provided.

PLUG gauges are being used in altogether too few instances, and those who are not familiar with them in inspection work in large plants would hardly dream of the rapidity with which they can be used and the work accurately measured. There are two types of plug gauges—the standard reference plug gauge and the limit plug gauge. Where holes are produced in large quantities the limit plug gauge is to be preferred, because greater interchangeability is secured, and there is an increase in production on certain lines of work. When only a small number of holes are to be measured, it will in some cases suffice to use a temporary gauge made from soft machine steel. For small gauges up to one inch in diameter, tool steel should be used, and for the larger sizes a good quality of machine steel, suitably case-hardened, answers the purpose admirably.

It is good practice to allow the gauge to season before grinding it to size. For most manufacturing purposes lapping is not necessary; a gauge from the grinder should be sufficiently accurate for all practical purposes. Some shops in an endeavor to save expense use soft steel handles and make the measuring part of the gauge of a good quality of high carbon tool steel. This economy is sometimes carried too far; so little material is really saved that the saving on material is more than outweighed by the extra amount of labor required.

A set of standard reference gauges should be kept in the tool-room and used only when checking or making new gauges. A record should be kept of all gauges. Before designing or making a plug gauge, it is essential that the following points are considered:

Reflective Features.

1.—If a standard plug gauge is required, would it be cheaper to buy the gauge?

2.—Is a standard plug gauge or a limit plug gauge best adapted for the work?

3.—If a limit gauge is decided upon, are the limits correctly determined?

4.—Is the gauge to be used on one or more operations?

5.—Can attachments be added to the gauge that will extend its usefulness?

6.—Can the gauge be quickly inserted and removed?

7.—Are all necessary corners rounded?

8.—Is the gauge absolutely foolproof?

9.—Have you specified the material to be used for the various parts?

10.—What parts are to be hardened?

11.—Is the gauge awkward to handle?

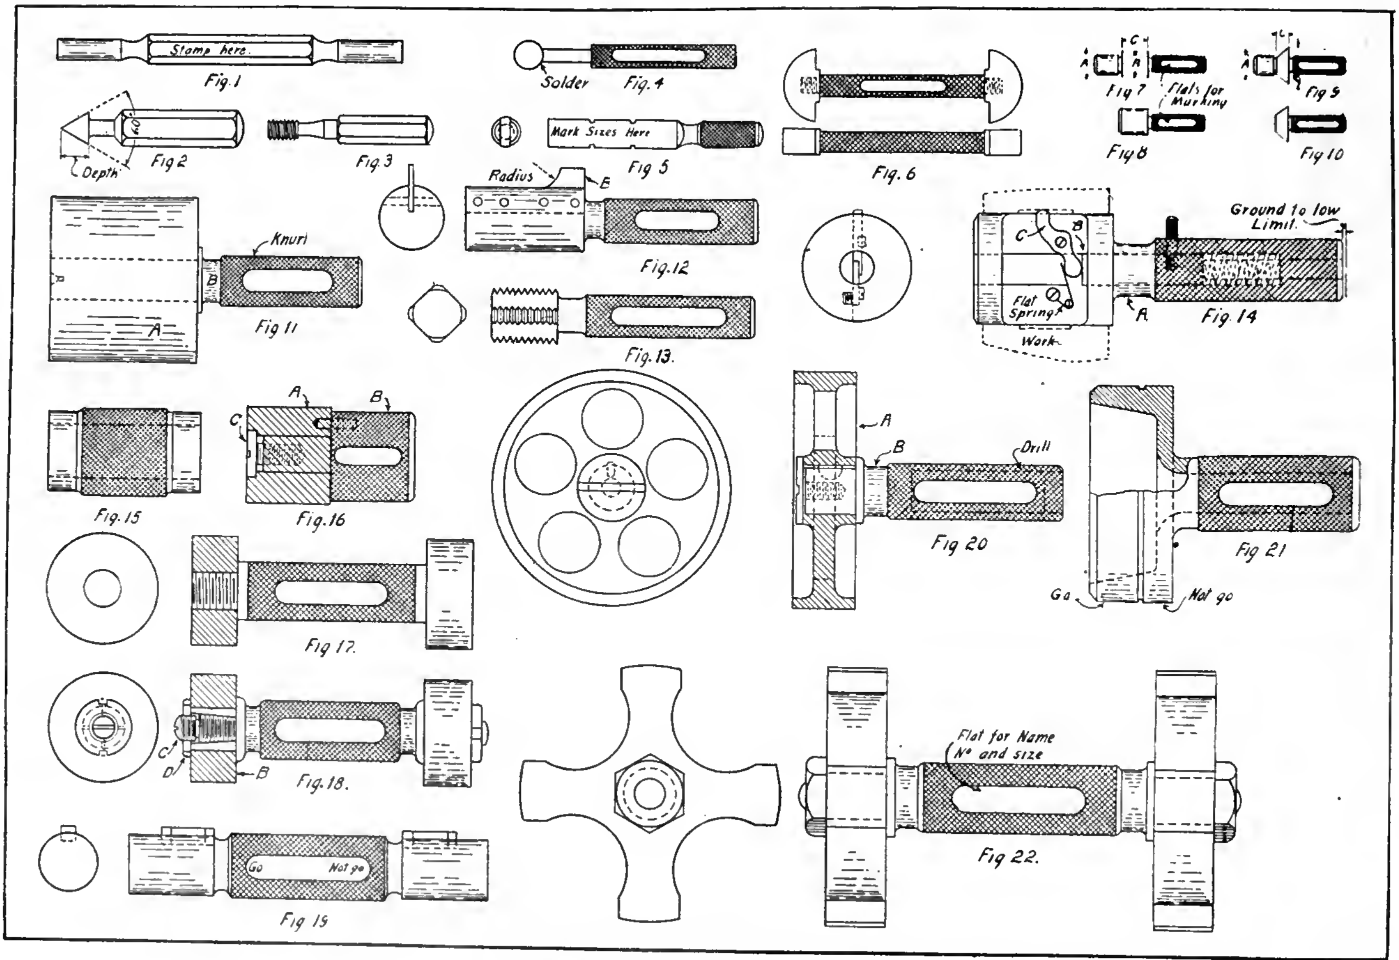
12.—If the gauge is too heavy, can it be lightened by changing the design?

13.—Is it cheaper to make a separate handle of soft machine steel?

14.—Can the handle be used on more than one gauge?

15.—Would a hollow handle be best?

16.—The handle should be knurled, if possible, and a flat provided for stamp-



DESIGN AND CONSTRUCTIONAL FEATURES OF PLUG GAUGES.

ing the name, number, and size of the gauge. Have you specified this in the drawing?

17.—Chamfer the ends of straight plug gauges slightly to insure easy entering.

18.—If the gauge is to be used in a blind hole, provide an air vent.

19.—Provide dirt grooves on thread plug gauges.

20.—Don't fail to remember that a highly-finished thread gives the best wearing qualities.

21.—If a taper hole is to be measured, can you use a plain or an indicating taper plug gauge?

22.—If an indicating gauge is decided upon, are the graduations spaced far enough apart so they can be plainly seen?

23.—If the hole is a large one, can a pin or rod gauge be used to better advantage?

Although plug gauges are most frequently used for measuring holes, their use can be extended considerably, as will be shown in the illustrations.

Small Plug Gauge.

Fig. 1 shows a limit plug gauge very much in use in typewriter, sewing machine and gun factories. It is usually made from bar tool steel of either hexagon or octagon shape. When large quantities of these gauges are used, it is very often the practice to turn and centre them in a hand-screw machine, and after being hardened they are finished in a cylindrical grinder. The reason for using steel of the shapes mentioned is to afford a firm grip for the hand and save the expense of knurling.

Centre Gauge.

The gauge shown in Fig. 2 is used to measure the depth of centres in the ends of shafts, etc.

Thread Plug Gauge.

In Fig. 3 is shown a thread plug gauge that can be used to advantage on small tapped holes. The threads should be left about .001 of an inch large; then after hardening they can be finished with a cast iron or copper lap charged with fine flour of emery or diamond dust.

For Small Holes.

For measuring small holes requiring great accuracy the gauge shown in Fig. 4 answers the purpose. It consists of a standard steel ball soldered to a machine steel handle. Only solder of a low melting point should be used. Points in favor of this type gauge are that no care is required to start the gauge straight, as is the case with a cylindrical gauge, and, if a ball shows signs of wear, it can be quickly replaced at small expense.

Fig. 5 is a limit gauge for measuring small holes. Two flats are milled to lighten it and provide a smaller measuring surface, a feature which is very often desired. The sizes are minimum and maximum on the ends and exact size in the centre.

Keyway Gauge.

In Fig. 6 is shown a Woodruff keyway limit gauge, consisting of a soft steel handle, having threaded ends, to which are fitted the measuring blocks. A gauge of this kind checks the width and depth of the keyway.

For Fillister Head Screws.

Figs. 7 and 8 show gauges used in gauging the size drill and counterbore of fillister head screws, A representing the body diameter of a fillister head screw, B the diameter of the head, C the length of head or depth of counterbore.

For Countersink Screws.

Figs. 9 and 10 show gauges used in gauging the size, drill and countersink for flat head machine screws; A represents the body diameter of a screw; B is the diameter, and C the length of the head. The angle of the head being 70 degrees, included angle.

Large Plug Gauge.

The amount of tool steel entering into the construction of the larger size plug gauges is no small item. Any scheme that will effect a saving in this direction is worthy of consideration. Fig. 11 shows how this may be done. The tool steel ring A is bored to about .002 of an inch smaller than the shank of handle B, which is made of soft machine steel. After the ring A has been hardened, it should be immersed in boiling water and allowed to expand. The handle can now be inserted into the hole without difficulty. After cooling, the ring will be securely held on the handle. It may now be ground to size, using centres provided for that purpose in the handle. When the gauge has become worn, it can be removed, annealed, and used for the next size smaller.

Radius Gauge.

An efficient means for measuring the radius at the mouth of a hole is found in the gauge shown in Fig. 12. It consists of a plain plug gauge, having a slot to which is fitted the hardened steel piece B, having the correct radius. This is firmly secured by means of the dowel pins shown in the illustration.

Relieved Thread Plug Gauge.

A feature that will be found of value in connection with thread plug gauges is shown in Fig. 13. Four flats are milled to provide space for oil and chips. Holes tapped in cast iron retain considerable oil and chips. Under conditions of this kind gauges of this type are the only kind that can be used to advantage.

Recess Gauge.

The gauge illustrated in Fig. 14 is used for gauging the depth of a recess. The plunger B is held against a bell crank, C by the action of a spring, on the end of the handle, A is ground a step that shows the limit within which the work must be machined. The end of the plunger is required to come within the step when applied to the work. A small knurled handle is provided to facilitate the entry and removal of the gauge.

Short Limit Gauge.

On turret lathes the space between the tools and the work is often very limited. For such conditions the double-ended limit gauge shown in Fig. 15 was designed. It will be noticed that its length is short compared to the diameter. A hole extends through the gauge for the purpose of reducing its weight.

Convertible Plug Gauge.

Another gauge designed for turret lathe use is shown in Fig. 16. It consists of a hardened and ground ring A, having a hole its entire length and counterbored to receive the screw C. The handle is made of machine steel, and carries a pin, D, which prevents part A from turning. Additional rings of various sizes can be made to fit the same handle, thereby reducing costs appreciably.

Built up Limit Gauges.

Fig. 17 shows a simple method of constructing a double-ended limit gauge. Two hardened steel discs are screwed on the threaded ends of a machine steel handle.

The form of gauge shown in Fig. 18 costs more to manufacture, and possesses no advantages that would warrant its adoption in preference to the gauge just described. Referring to the illustration, it will be seen that the ends of the handle A are threaded taper to receive the expansion screws, C; these are held in place by the lock nuts, D. The measuring discs B are made of tool steel or machine steel suitably carbonized.

Keyway Testing Gauge.

Fig. 19 is a gauge used for testing the proper location of keyways. Each end is a plain plug, to which is fitted a ground steel key, having the proper limit, and secured by screws or solder. All parts should be hardened.

Extra Large Gauges.

When a plug gauge gets over 3½ inches in diameter, weight is a factor to be considered, and calls for alteration in the design. An example is shown in Fig. 20. The measuring disc (A) is grooved out on the faces, and five holes provided, as will be seen in the illustration. The handle (B) is held by means of the key and screw shown.

Single End Limit Gauge.

A good example of a single end limit gauge is shown in Fig. 21.

Relieved Limit Gauge.

Another form of limit gauge is illustrated in Fig 22. This type can be laid on the machine or bench without rolling off. The discs are secured by means of a nut screwed on each end of the handle.

REFINEMENTS IN MECHANICAL DRAWING.

By James E. Cooley.

THE symbols and conventional methods used in mechanical drawing have been so long established that drawings as a rule have undergone very little change and improvement compared with other systems and practices relating to the machine industry. The most of us are familiar with an advertising phrase that runs something like this: "We could not improve the goods, so we improved the package." This may not have a direct application to a drawing, but it serves to show that while a limit may be reached in improving a certain article, it is possible to go a point beyond and refine something in connection with it. This is true of mechanical drawings, machinery, or even man himself.

Refinement of Individual Detail.

A doctor may be a first-class surgeon, by his skill and ability may have reached a high mark in his profession, but, beyond his skill and ability, though he may go no further, it is possible for him to refine his methods in the handling of his cases or whatever relates to his respective calling. Such is true of the draftsman and the drawings he makes; he cannot perhaps improve the symbols or methods in use, but it is possible to refine the arrangement of these so that his drawings will have a neater and better appearance.

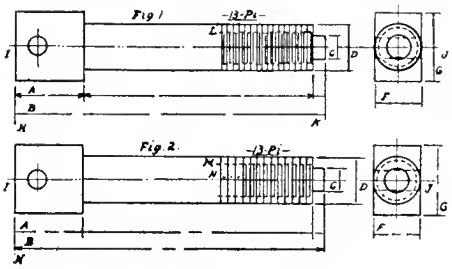
Omissions and inaccuracies are to be noted more or less on mechanical drawings, but it is not to be assumed by this that the average draftsman is careless. In many cases he is a hurried individual, produces work that has a hurried appearance, he is subject to others "higher up," and not allowed time to produce drawings with any semblance of finish or neatness of execution.

Drawings a Necessary Evil?

An impression has gone forth and has gained widespread publicity that drawings are a "necessary evil." Nothing is further from the truth and sense in a report of this kind. That which is vitally important as an aid in producing work accurately and economically cannot be an evil. The evil would be in trying to machine or fit a piece of work without the aid of a drawing. It is poor economy to rush or try to cheapen work in the drawing-room in order to save time and expense in this particular branch of the machine tool industry. It is not uncommon to see drawings, such as pencilings, taken direct from the drawing board and used, with edges untrimmed, having no border lines, superfluous lines unerased, or even blueprints in use that have not been given proper time for exposure, the color being so mottled that the lines and figures are hardly readable. On this principle of doing work, one might assume that the machine work was being produced in the same manner or on the same scale.

Average Drawing Imperfect.

However, it can be said with truthfulness that no matter how much pains have been taken, the average drawing is a poorly executed affair. This may not be discernible to the user, it may not be noticed even by draftsmen, but it can be shown on examining any drawing that the proper finish as regards symmetry, or the proper placing of certain lines, figures, etc., in their relation to each other has not been or never is given any consideration. The two views of a special stud, Figs. 1 and 2 that accompany this article, show clearly a few important points either unknown or overlooked by draftsmen and others, but which if kept in mind and practised would add



REFINEMENTS OF MECHANICAL DRAWING.

considerably to the general appearance of a drawing.

The first to be mentioned are the dimension lines. These are usually placed on drawings with little attention to order or arrangement. Note the lines A-B, Fig. 1, unevenly spaced from the stud-head. See same lines in Fig. 2, placed an equal distance apart. Note again the lines C-D, Fig. 1, between the end of the stud and side of stud-head, and the same lines below evenly placed across this space. Also see lines F-G, Fig. 1, denoting thickness of head; these are badly spaced. How much neater they appear as placed in the figure below. A fault common to many draftsmen is to draw witness lines one longer than the other at each end of a dimension line, as seen at H-K, Fig. 1, also in several other places in this figure. All the witness lines in Fig. 2 overhang equally from the dimension lines.

Centre lines as usually drawn have a hit-and-miss appearance, because the lengths of the dash lines are seldom alike. It is also noticed that the ends of the line as at I and J, Fig. 1, terminate unequally from the views. In Fig. 2, this centre line is evenly spaced, both in the dash and dot, and terminates alike at the end of the two views through which it passes.

It might be said here that, ordinarily, draftsmen cannot take the time to put all these finer touches to a drawing. It does not require any extra time; it is done with the eye, by practice and by taking pains. It is simply the difference in being methodical in one's work or slipshod.

Attention is further directed to making arrow-heads. These should be slightly curved and darkened so they will show up plain on a blueprint. Those often shown, as in Fig. 1, resemble a "pick-axe" as much as they do an arrow-head.

Screw Threads.

Lines representing threads should be spaced off with dividers, because the number of threads per inch are either exceeded, or not enough are shown when guessed at with the eye. The lines showing the depth of thread are as a rule drawn uneven, which appear zig-zag as indicated by the dotted lines L, Fig. 1. It is an easy matter to draw two pencil lines as M, Fig. 2, and make all these thread lines equal lengths, giving the drawing a much neater appearance. Small dots made with the pencil as suggested at N, Fig. 2, will aid the draftsman in drawing these inner thread lines central between the outer thread lines.

Enough has been said here to show in a general way what constitutes the making of a first-class drawing, being simply careful attention given to each detail. The inch marks should be an equal distance on all figures, the border lines should be the same thickness on all sides, the drawing should be evenly trimmed off on the edges, and so on. Such painstaking care will show its mark where careful attention is given to the smallest of these details, and will add wonderfully to the neatness and general appearance of a drawing, all of which may be rightly called refinements.

When a handful of rags, paper, cotton or wool are soaked with oil or varnish (especially drying oils) and are thrown in some place where they cannot get much air, they may be expected to take fire sooner or later. A little dampness makes them take fire quicker. They make heat by themselves. The heat gets greater, little by little, and the more porous the stuff the oil is on, the greater the surface of oil exposed to the air, if the amount of oil is not large enough to fill the pores completely. If there is sawdust around, probability of fire is increased. Why these harmless looking oily rags should take fire by themselves is something that only chemists can explain. It does not matter how this strange thing happens, but it does happen, and that is all we need to know for our purposes. The thing is to get rid of the rags, and not throw them in corners or under machinery.

The Successful Production of Large Steel Castings

Staff Article

The development of certain branches of mechanical and electrical engineering during the last decade has compelled foundrymen to strain every effort in order to keep pace with the ever-increasing demands of machine builders. A careful perusal of the following article will show that Canada is maintaining a satisfactory position in the production of large steel castings, such as are required to meet the most exacting conditions both in size and quality.

THE difficulties of making steel castings increase very rapidly after the weight and size pass a certain limit. Extra heavy castings such as are described in this article call for more than ordinary shop equipment, special shipping facilities and very often great ingenuity on the part of the foundry staff.

Castings such as are described in this article are being continually produced at the plant of The Canadian Steel Foundries, Longue Pointe, Montreal. Fig. 1 shows a large cast steel roughing roll of about eight tons and similar to those used in the largest steel mills. Let us follow the different stages of manufacture through which this piece passes beginning at the pattern shop, the various processes encountered in the foundry, until it leaves the finishing lathe and is ready for shipment.

Moulding a Large Roll.

For a more ready understanding of the method of forming the mould it is better to give first a description of the flask.

In this case the latter consists of two halves of a cylinder made of cast steel, two inch wall thickness, reinforced by circumferential flanges and longitudinal ribs of the same dimension. Each half of the flask is built up in short sections bolted together which make them adaptable to the making of long or short rolls as the occasion demands. On one end of each half is bolted a semi-circular steel plate forming the bottom; the metal is poured in at the other end with the flask standing in an upright position. The lower half of flask, known as the drag, consists of a quarter of a circle plus a square, the side of which is equal to the radius of the cylinder. This is done in order to give a bearing to the flask on the floor. In the corner of this square is also placed the riser or aperture through which the metal rises and enables the operator to tell when the mould is filled, it being impossible to detect same through the filling gate.

Specially Prepared Sand.

The next consideration is the sand. It is not to our purpose to enter into an analysis of the sand, so called, which consists of a mixture of special earth, gluten, fire clay, molasses, and other ingredients, furthermore than to say that the object sought after is to obtain a homogeneous and compact mass in the mould. Each foundry has its own practice which amounts almost to a trade secret. The prepared sand is then shovelled into the lower half of the flask and we now come to the most important part of the operation, that is, the forming of the mould proper. For the fashioning of the shape of the roll in the sand no pattern is used; instead a long one inch board, shaped out very much like a ratchet, is employed. There are two hinges on this board, which swings on a horizontal shaft, which has its bearing at either end of the flask. This board, commonly called a sweep, is revolved on its axis in the sand, the teeth on the board forming the ridges on the roll and the spaces between the teeth giving shape to the hollowed out sections on the casting. This method is rapid, and does away with the making of an expensive pattern, which in this case would not only prove unwieldy in handling, but also very liable to breakage. The upper half of the flask or cope, as it is called, is made in the same manner as the drag.

The flask with contained mould is lifted by a crane and carried across to an oven car, on which it is subjected to a surface treatment before it is baked. This treatment consists in painting the mould with a heavy solution of molasses and water. The two halves are then placed in the oven for a thorough baking. The resultant mould must be much harder and more solid than for cast iron. The time taken for the baking process is twelve hours, after which twenty-four hours are allowed for cooling off. The drag and cope are now firmly bolted together and stood on end ready for the pouring of the molten metal. The foundry is equipped with two 30-ton furnaces of the acid open-hearth type. For firing purposes ordinary fuel oil, under a pressure of 80 lbs. per sq. in. and air at 100 lbs. per sq. in. are fed into the furnaces. Five hours are required to melt a charge with a consumption of about 35 gallons of fuel oil per ton of metal. A 40-ton bottom pouring ladle is used, into which the entire charge from the furnace is run.

FIG. 2.—PARTICULARS REQUIRED FOR MACHINE MOULDED GEARS.

FIG. 1.—CAST STEEL ROLL. WEIGHT 8 TONS.

Pouring the Metal.

The ladle, of the bottom pouring type, is made from heavy boiler plate lined with fire-brick. A graphite plug of truncated conical shape is used as a stopper for the pouring hole; this plug is connected to a rod which runs through the molten metal, and is insulated from the latter by means of fire-brick discs. The opening and closing is operated by means of a lever attached to the side of the ladle. The life of a graphite plug is considerable, one lasting sometimes for a week. The mould is now poured by one of the foundry cranes carrying the 40-ton bottom pouring ladle, spoken of above, and slowly filled from one end. This operation takes about four minutes. The three or four feet of the roll, which is excess metal, causes a uniform liquid pressure to be exerted full length of the casting and tends to counteract the contraction of the metal while setting. This extra metal is technically known as the crop and runs about 40 per cent. of the total weight of the casting.

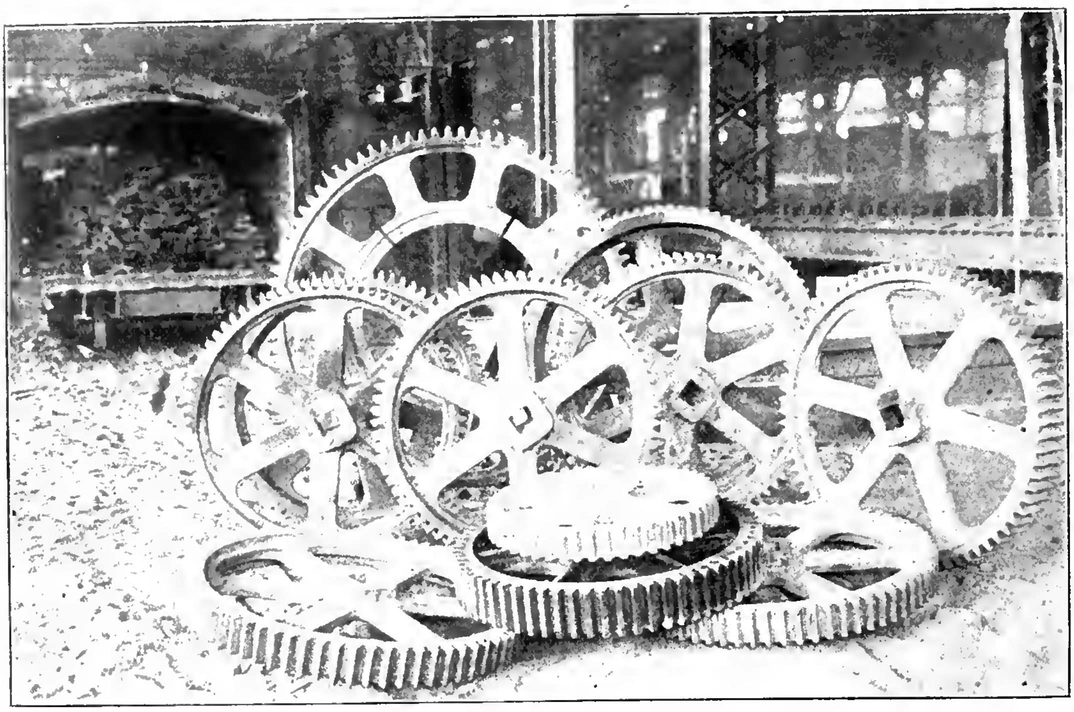

FIG. 3. MACHINE MOULDED GEARS.

The casting is allowed to remain 24 hours in the mould, after which it is removed to the annealing oven. The latter is a long shallow pit, temporarily arched over with brick-work during heats. The rolls are here subjected to a temperature of 900° F. for about 12 hours. They are then allowed 24 hours in which to cool off. This annealing process produces a uniformly soft casting, at the same

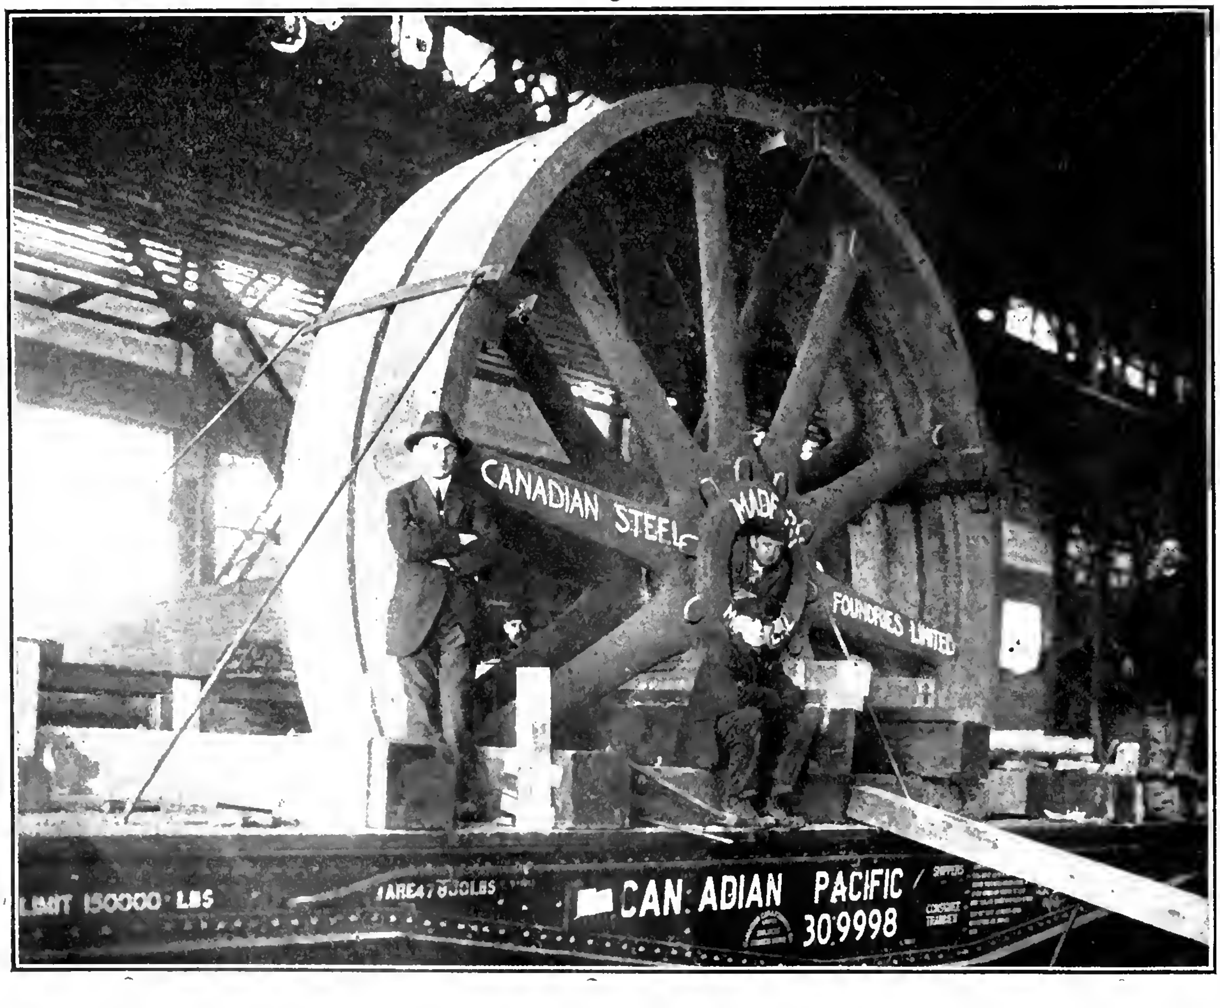

FIG. 5. LARGE STEEL CASTING FOR ELECTRICAL MACHINERY. WEIGHT 19 TONS.

time removing the chill strains set up by unequal rates of cooling. In Fig. 1 it will be noticed that the ends of the roll just outside the bearings are grooved; there are three of these circular slots on each end, their purpose being to engage with three internal teeth of a short sleeve, and act as a flexible coupling or universal joint. The wobbler is moulded only on one end, and has to be machined on the other after the riser or crop, spoken of above, has been cut off. The cutting off process is rapidly performed by means of the oxy-acetylene blow torch. The roll is finally turned down to size on a lathe, and is ready for use.

Machine-Moulded Gears.

In the past few years there have been great strides made in the moulding of steel gears without the necessity of expensive patterns. This is a fact that is not as widely known to the manufacturer as it might be, and one that will often obviate the necessity of a long and tiresome shut-down. The only information required is such as is specified on the form shown in Fig. 2. To such perfection has the machine moulding gear machine been brought that very often a gear can be made and shipped before a pattern could be completed.

Fig. 3 shows a few gears made by the machine-moulding process, and Fig. 4 shows the method of moulding. When sufficient care is exercised in making up the tooth block, the gears will be found to be remarkably true and machining will not be required. The tooth-block usually contains two teeth of the same pitch and dimensions as those on the gear to be moulded. Sometimes more than two teeth are used, but as the time is mostly taken up in the ramming and scarcely any in drawing the tooth-block and revolving the machine, it is not of any material advantage to employ more than two teeth. Moreover, when using a block of two teeth only, a slight alteration in the diameter of the gear can be made, since the "tooth space" only is used, so that the same block can be employed to make a pitch full or bare, which is decidedly convenient in jobbing and repair work. Gears can also be made having one or two teeth, more or less, than the number in the gear for

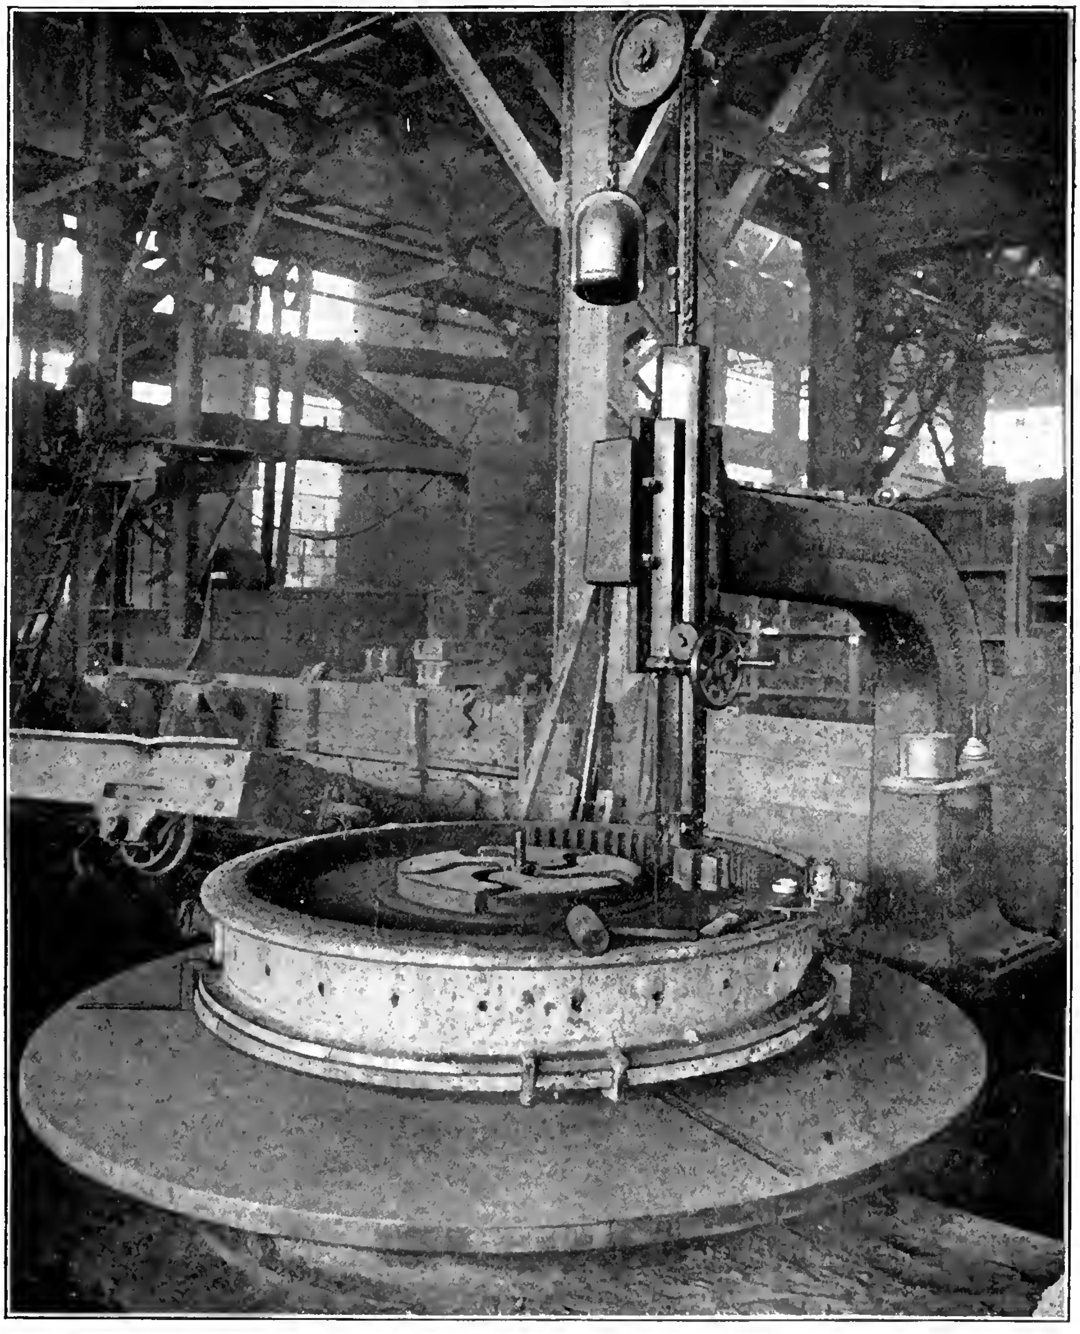

FIG. 4. MOULDING MACHINE PRODUCING MOULD FOR LARGE GEAR WHEEL.

which the block was originally made. Fig. 5 shows a good example of a large steel spider intended for high speed, heavy duty, electrical equipment, which must necessarily be free from defects of all kinds. An idea of the size of the spider may be gained by comparing the bore (in which one of the men is resting) with the height. It is 16 ft. 6 in. diameter, with a 42-in. face, and weighs 37,930 lbs. There is a clearance of just six inches between the bottom of the spider and the railroad track. Note the clearly-defined bolt bosses and clean outlines of arms and rim. The forming of the mould is somewhat similar to that employed in the case of the roughing roll. In that case a sweep was employed, which revolved in a vertical plane around a horizontal axis, whereas in the case of the spider the sweep is revolved in a horizontal plane around a vertical axis pivoted at the centre or hub. The spaces between the arms are cored out and a riser placed on each arm. The molten metal is poured at the hub. The mould baking and annealing processes are somewhat similar to those employed as described above. Fig. 6 shows an extra heavy steel casting, as used in the piers of the Quebec Bridge. This piece was made from what is known as a skeleton pattern, merely a rough box, the main difficulty being the coring of the holes shown in the photograph.

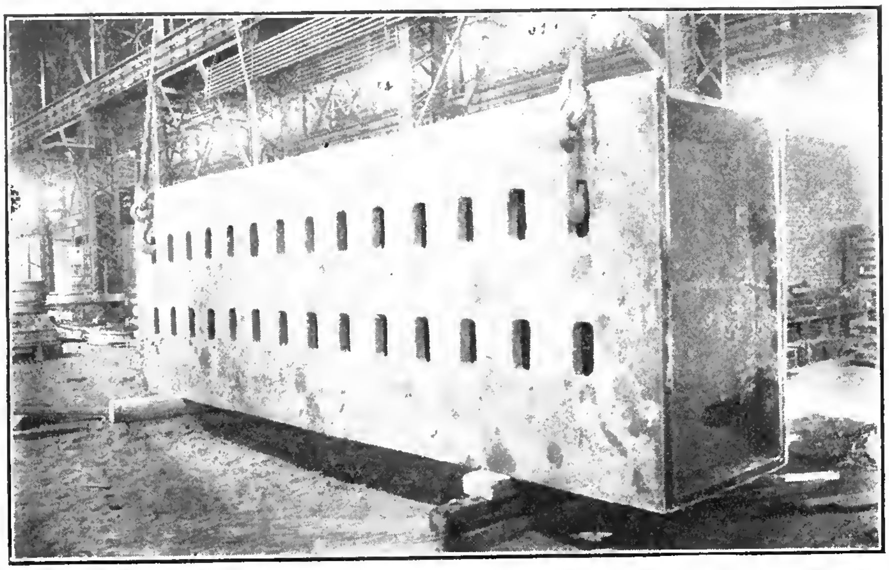

FIG. 6.—STEEL CASTING TO FORM PART OF BRIDGE PIER.

NOISY GEARS.

THE question of noisy gears being always an acute one amongst automobile and machine tool manufacturers, the writer recently sought to confer a benefit upon humanity by trying to discover the prime cause of the trouble. After some thought it seemed that the most natural way would be to study the question from an acoustic point of view. The fact that a sound was produced by two gears running in mesh was sufficient indication that there was some vibration going on, which was communicated to the ear by the intervening air; to find out how this was produced was the problem.

In the case of a gear box having a number of gears in mesh, the sound could only be characterized as an objectionable noise, but with a single pair of wheels, when they were running sufficiently fast to produce a definite sound, it was an easy matter for even a moderately trained ear to identify it as a single note on the musical scale. In any case, it must be admitted that a noise is but an unpleasant combination of notes.

For the purpose of argument a theory was therefore formed to account for it, and it was assumed that in the interstices between the teeth in mesh small quantities of air were trapped, and that these were hurled out at sufficient frequency to produce an audible musical note, the general action resembling that of the siren. A series of experiments to test this was carried out in the following manner:—

Experimental Test Data.

A gear of 36 teeth 12 pitch was mounted on a mandrel between centres in a lathe, and on the saddle was fixed a bracket which carried a stud on which another gear was mounted. The number of teeth on this gear does not enter into calculation, as will be seen. The lathe was then started, and the gear on the cross slide moved forward to mesh with the gear driven by the lathe. In this particular case the lathe spindle made 484 turns per minute, and it was observed that whilst the pitch of the note did not alter, the volume of sound considerably increased as the gears were moved closer together. The pitch of the note was then recorded by means of an adjustable tuning fork. The gear wheel having 36 teeth and making 484 turns per minute, it is obvious that the number of teeth passing a given point per second would be:

$$\frac{484 \times 36}{60} = 290$$

That is to say, according to the theory, 290 was the frequency of the note. Now 290 is as nearly as possible D on the standard musical scale, so the next step was to strike D on the piano, and, as was expected, the note was exactly in unison with that of the tuning fork.

The experiment was repeated with different gears and speeds, but with the same result; it was always possible to predict the note by calculation. The converse experiment was also performed in which the spindle speed was accurately calculated from the note. This theory would seem to have some corroboration from the quietness of the herring bone gear, probably due to the interference between two series of wave motions whose wave fronts are inclined at an angle to each other.

Even with a theoretically perfect tooth curve, so long as there were any air spaces, there would still be a certain amount of sound, a conclusion that seems somewhat heretical. Of course in an imperfectly cut gear there is a series of actual impacts and scrapes between the teeth as they come in contact which greatly increases the volume of sound.

Whether the theory be right or wrong, one thing is certain, namely, that the pitch of the note is a simple function of the number of teeth passing a given point per second, and that there is a distinct connection between each tooth and each vibration.

The experiments are probably interesting only from an academic point of view, as without a remedy they are valueless, but still, they are offered here as suggesting a comparatively new line of thought.

So far only one practical application has been suggested, and that came from a rabid motorphobe friend of the writer. It was, that all automobile makers should be compelled by law to fit their cars with gears of uniform pitch and ratio, the police being musically trained and armed with tuning forks. Excessive speed could then be easily detected by the preceding method.—Herbert's Monthly.

G. R. G. Conway, until recently chief engineer of the British Columbia Electric Railway Co., Vancouver, B. C., will establish an office as consulting engineer at Toronto, Ont.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

NEW CONSTANT SPEED DRIVE PLAIN GRINDING MACHINE.

ANOTHER addition to the already extensive line of single pulley constant speed drive machine tools, built by the Brown & Sharpe Mfg. Co., Providence, R.I., is shown by Figs. 1 and 2, which illustrate their new No. 11 plain grinding machine, which has a capacity for work up to 32 inches length and 6 inches diameter.

The usual advantages of a self-contained drive, such as elimination of complicated overhead works, a wider selection of speeds and feeds, better adaptation to a motor drive, etc., are all to be found in this new design. The method of application is particularly interesting, as it brings out some new ideas in the design of drive for different parts of the machine.

Power is transmitted to the machine through a main driving shaft running in two large taper roller bearings bolted to the rear of the machine. This shaft, running 900 r.p.m., is driven with a 3-in. belt from a simple counter-shaft, containing one tight and loose pulley and one driving pulley to a large pulley located on the end of the main driving shaft, as seen in Figs. 1 and 2. A large pulley located centrally between the two roller bearings on the main driving shaft drives the wheel spindle, with a pulleys run on taper roller bearings, supported in a heavy swinging bracket so constructed as to follow the transverse movement of the wheel-stand, thus keeping the desired tension upon the driving belt, regardless of the position of the grinding wheel, and insuring accurate feeding of the wheel under all conditions. The slack in the belt, due to the difference in diameter of the wheel spindle pulleys when changes in wheel speeds are made, is taken care of by the top idler pulley, which is provided with separate adjustment, making it possible for the operator to place any desired tension on the wheel spindle driving belt. Referring to Fig. 2, this drive as well as the head-stock and table traverse drive, may be seen.

The table traverse movement is driven by a sprocket A, Fig. 2, located on the speed case, driving sprocket B being located on the table traverse reversing mechanism, which is self-contained in a case fastened into the bed of the machine from the front. The head-stock is driven from the speed case by a sprocket C to a double sprocket D acting as an idler, to a hardened splined sprocket E. A splined shaft supported in bronze bearings under each end of the work-table, sliding in the splined sprocket E, drives, through a chain and sprockets, a telescopic shaft and universal joints, upon a sprocket running on tapered roller bearings around a fixed spindle, which firmly holds a dead centre in such a manner as to become practically an integral part of the head.

All chain drives throughout this machine are of a silent type, eliminating slippage, but providing the desired flexibility and giving a smooth, steady drive to the work. Easy means of adjustment are provided in all cases. The tapered roller bearings used are of an adjustable type, and are lubricated by means of grease cups.

A very important step in the evolution of this machine was taken a short time ago when a simple and efficient speed and feed change mechanism was developed. The mechanism was briefly described in this paper at the time, but it has such an important bearing on the present self-contained drive that an illustration and outline of its principal points are well worth while.

The drive from the main shaft of the machine to the sprockets in the speed case that drive the head-stock and table is of a powerful multiple friction disc type. It enables the operator to easily start and stop the work or table movements without shock, and gives practically universal choice of independent speeds and feeds.

Fig. 3 shows the interior of the speed

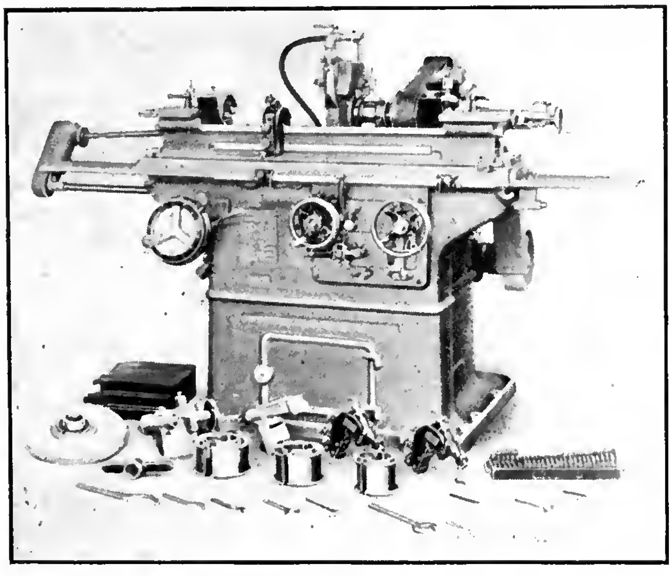

FIG. 1. CONSTANT SPEED DRIVE GRINDING MACHINE.

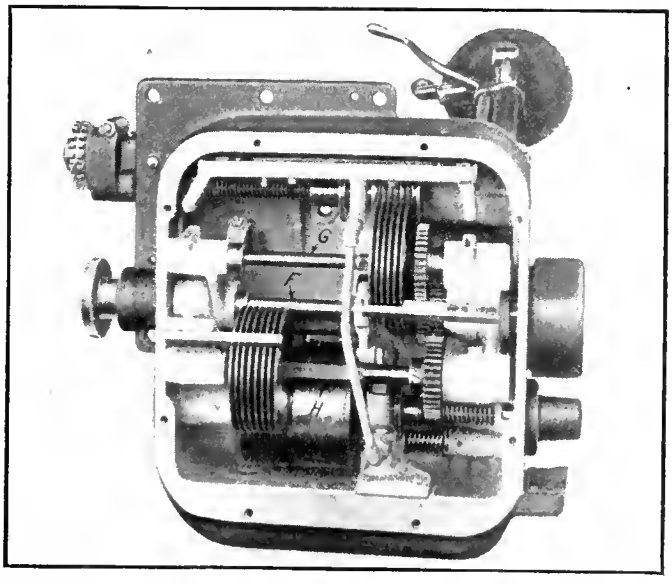

FIG. 3. SPEED CASE FOR CHANGING SPEEDS AND FEEDS.

3-in. belt running over two idler pulleys. Changes in wheel speeds are obtained by means of split pulleys on the wheel spindle that can be quickly interchanged without removing the belt. The idler which in turn transmit power to the head-stock chain. The splined and telescopic shafts are clearly shown at the end of the table in Figs. 1 and 2.

The work driving plate is mounted case, the back having been removed. From the main driving shaft F power is transmitted through gears to two separate driving shafts, G and H, running at a constant speed. These shafts carry

a series of hardened steel discs, ground slightly convex, and each meshing with another series of hardened steel discs. The latter discs have a rim at their periphery, bringing the point of contact always at their extreme edge. The driving shafts are mounted in swinging brackets pivoted on the main driving shafts bearings. They are swung toward or from the driven shafts, carrying the driving discs toward or from the centre of the driven discs, thus obtaining the desired

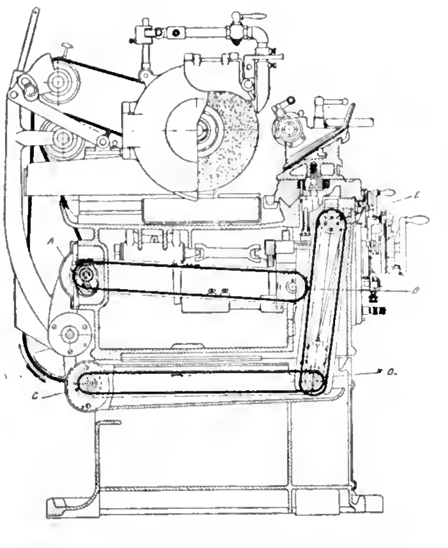

FIG. 2. NEW CONSTANT SPEED DRIVE PLAIN GRINDING MACHINE.

changes in the speed of the work or feed of the table by decreasing or increasing the radius of the driving discs. A continuous flow of oil from a pump direct connected to the main driving shaft furnishes lubricant for the entire case.

The control of the speed case is governed by three levers grouped around a dial mounted at the left of the machine within easy reach of the operator. (See Fig. 1.) The lever marked "Head" controls the head-stock or rotation of the work. Any desired number of revolutions may be obtained, ranging from 82 r.p.m. to 412 r.p.m. A second lever marked "Table" changes the rate of table traverse. The dial is graduated to read in inches per minute. Any desired change from 13 to 181 inches per minute may be obtained. A third and longer lever serves to instantly stop and start both work and table simultaneously without stopping the grinding wheel.

Another new feature found in this machine is the independent automatic cross feed, which enables the wheel to be fed automatically into the work without traversing the table. This feature is especially valuable and efficient when the portion of work to be ground is not as great as the width of the grinding wheel. In feeding the wheel straight in, marked economy in production may be secured. This independent automatic cross feed is driven from the table traverse mechanism, and operates the ratchet arrangement of the regular automatic cross feed. As a result, the full number of changes of feed that can be made with the regular cross-feed mechanism are available. These may be increased or decreased by changing the speed of the table traverse mechanism with the table traverse feed change mechanism, giving practically a universal selection of feeds from the coarsest to finest that are ever required. A positive safety lock is provided to prevent throwing in the table traverse when the independent automatic cross feed is in operation.

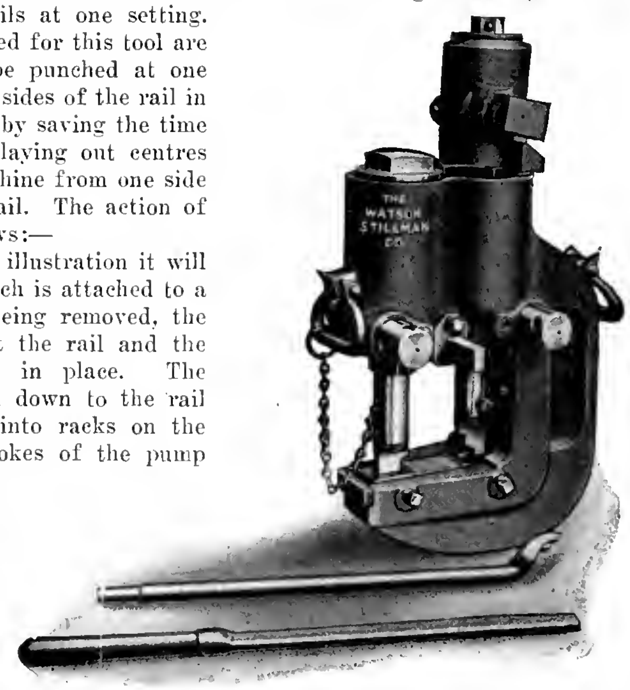
These important features in design in connection with the general heavy, compact and rigid construction, the handy arrangement of operating levers, hand wheels, etc., fit this new machine particularly for the requirements of manufacturers on dead centre work, either straight or taper, within its capacity.

DUPLEX SPIKE SLOT HYDRAULIC PUNCH.

THE Watson-Stillman Co., Aldene, N.J., has brought out a new hydraulic punch for cutting out two spike slots in railroad or conductor rails at one setting. The advantages claimed for this tool are that two holes can be punched at one operation on opposite sides of the rail in exact alignment, thereby saving the time usually consumed in laying out centres and changing the machine from one side to the other of the rail. The action of the punch is as follows:—

By referring to the illustration it will be noted that one punch is attached to a chain. This punch being removed, the tool is placed against the rail and the loose punch inserted in place. The punches are then run down to the rail by pinions, meshing into racks on the rams, and a few strokes of the pump lever completes the operation. The whole action, we understand, takes less than two minutes, and involves little effort.

The punch is compactly built, and is so designed that the greatest strength is obtained with the least possible weight. The working parts are readily accessible for cleaning, and the punches and dies are removable for sharpening, renewal, etc.



DUPLEX SPIKE SLOT HYDRAULIC PUNCH.

TRADE RETURNS WITH GREAT BRITAIN.

THE following are the official figures of trade between Canada and Great Britain in the undermentioned articles during June:

Exports From Canada.

	June, 1915.	June, 1914

The Leon Torpedo.—The form of drifting mine used by the Turks is believed to be the Leon torpedo, which resembles a short Whitehead torpedo. It can be discharged through a torpedo tube or dropped overboard. It is not an automobile torpedo, but a freely-floating mine, which can be set to oscillate between any depths below the surface. The torpedo sinks until automatically the propeller is brought into use and drives it upwards again, when the action of the propeller ceases. There is a time arrangement embodied by which the duration of its floating can be regulated.

THE "RETURNS" VALUE OF ADVERTISING.

IN the determination to take advertising space in a publication—domestic, trade or technical, what, we ask, are the considerations on which the decision usually depends? At first sight the query would not only seem to be unnecessary, but bear evidence as well of apparent lack of knowledge of human nature. Without, therefore, giving the slightest thought to the matter, a great majority of those appealed to would unhesitatingly reply that at the very least direct results equivalent to the money spent would be desired and ultimately expected.

There is little of sentiment, it would appear, in advertising, as a consequence there is generally little disposition on the part of the advertiser to either realize that he may or should be a benefactor even to a small extent. The general tendency is, as we have already said, towards direct and sufficient-in-value returns. Scant consideration, if any, is extended to what are known as indirect results, the smack of philanthrophy about these being considered altogether "unhealthy" from a business standpoint.

In spite, however, of the views so generally and tenaciously held, and the persistency with which we endeavor to put them into practice, isn't it true that in spite of what we achieve or otherwise in direct results from our advertising, we actually achieve more in the indirect sense, and become in very fact benefactors—even philanthropists in spite of ourselves

Most manufacturing concerns advertise because it pays them to do so; some don't, because they believe they can do equally well without advertising; others again may or may not advertise because of the fact that their particular product belongs to one of a few selective industries in which, although competition may be and is more or less keen, no possible monetary return is realizable.

Concerning the latter classification and specifically those who advertise—quite a few do so, the action taken may be meant to indicate simply a desire to keep the firm name before the public, a by-no-means unwise proceeding. There is, however, much more involved in such advertising than simply keeping one's name before the public, and just here it seems, that, were nothing else considered, some sensible percentage of every advertising appropriation should be excluded from direct results expectations and be ear-marked "the public eye only."

Advertising of any sort has an educative value, the latter being unrestricted to the mere bringing of buyer and seller together. It has made possible the placing in the hands of the public, at little cost, literature which aids them in every conceivable condition, circumstance and difficulty, and in no sphere is this so fully exemplified as in the arts, crafts and manufactures. Publications relative to each of these are recognized necessities, as only through their medium are the administrative and operative staffs of any particular industry kept in prompt, intimate touch with developments which may affect its welfare either way.

Through the opportunity of becoming a subscriber to a trade or technical journal the operative mechanic adds to his capabilities, and as a result enhances his earning capacity relative to his employer as well as to himself. Under such circumstances then, should not a further and quite husky percentage of every advertising appropriation be excised from the direct returns expectation column of the ledger and be esteemed as indirectly reflected in the increased efficiency and output of the shop. It seems to us that even the most progressive of our manufacturers realize in but small degree, if at all, that advertising appropriations are a most potent factor in the education and training of their employees.

Advertising, in that it places within easy reach of operatives of every class and grade a reputable trade or technical journal periodically and regularly, warrants expression of our conviction that whether systematically, intermittently or never practised, there is need for a complete change of viewpoint. The general attitude relative to it is that of an expenditure chargeable to profit and loss account, whereas, when properly considered and allocated, its service rendered belongs more truly to an expenditure on capital account, and is therefore an asset subject to a regular depreciation percentage only.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Toronto, Ont., July 27, 1915.—There are no developments of any particular importance to note this week. Factories working on war orders continue busy and the hope is freely expressed that more orders for war equipment will be placed in Canada. David A. Thomas, the representative of the Imperial Government, has arrived in Ottawa to confer with the Shell Committee. He will also investigate the capacity of Canadian plants to produce munitions, but not place any orders, this matter being in the hands of the Shell Committee. It is understood that he will visit Toronto and Montreal in due course. The situation in regard to the shell industry is unchanged, but developments may be looked for in a month or six weeks. Those firms, however, who contemplate going into the shell business, are ordering the necessary tools and equipment so as to be ready when new orders are distributed.

Considering the extraordinary conditions prevailing owing to the war, there are many reasons to be satisfied with the present outlook from a purely business standpoint. The crop reports are distinctly encouraging, a gratifying feature at any time, but especially so during such times as these.

The country has benefited considerably by the large amount of money that has been distributed in payment for war

orders. Further, the trade returns for June are decidedly encouraging as they show a large increase in exports and a decline in imports and therefore a more favorable trade balance. There is no reason why this should not continue, in fact there are indications that such will be the case.

Steel Market.

The general situation in the steel trade is much the same as has prevailed during the past few weeks. The heavy demand for steel bars and forgings for shells continues and indications point to a continuance of this condition for some time to come. War orders for other steel products amount to fair tonage in the aggregate, but in ordinary lines there is little of interest to note. There is, however, a fairly optimistic tone in the market based on the hope that foreign business will develop to the ultimate benefit of the steel trade. Merchant business continues quiet and the building trade is not showing any pronounced activity.

There is little change to note in the galvanized sheet situation. There is a tendency to shade prices but some makers are still out of the market on account of the spelter situation. Prices of No. 28 black sheets are firmer, but the demand is light.

Conditions in the steel trade in the States continue to improve, principally on account of export business which continues to expand. The Steel Corporation are operating at about 91 per cent. of the ingot capacity and other concerns are showing a similar activity. Quotations on Bessemer and open hearth steel billets have advanced respectively to $22 and $23 per ton, Pittsburg, while prices of bars, plates and shapes are firm, with a higher tendency.

Pig Iron.

There is little of importance to note in this market. Foundries generally are very quiet and operating at considerably reduced capacity. Quotations are unchanged.

Scrap Metal.

The demand for heavy melting steel is improving and quotations are firmer. Copper and brass scrap continue in good demand and prices are holding firm. Wrought iron and cast iron scrap are quiet. Prices are given in the selected market quotations.

Machine Tools.

Prospective shell manufacturers are sending out inquiries for equipment which are keeping local dealers busy. Makers of machine tools are filled up with orders and deliveries are getting worse rather than better. There is nothing particularly new in the situation but developments may be expected when further orders for shells come to be distributed.

Supplies.

Business continues brisk in machine shop supplies and quotations are holding firm. The long expected advance in leather belting has materialized, the new discounts being as follows: Extra Heavy 50%, and Standard 50 and 10%. Tool steel has already advanced and the situation is serious owing to the scarcity of tungsten. For the same reason an advance in prices of twist drills is expected, there being at the same time a heavy demand. Solder "Half and Half," is weaker and is now quoted at 26¾c per pound. The linseed oil market is unsettled with a variation in prices, but the figure given in the selected market quotations may be taken as a fair average. Lead wool has advanced 1c and is now quoted at 10c per pound.

EQUIPMENT FOR AUSTRALIAN RAILWAYS.

Tender forms, specifications and drawing have been forwarded by D. H. Ross, Trade Commissioner at Melbourne, for equipment required by the Victorian Government railways. These tender forms are open to the inspection of Canadian manufacturers when received at the Department of Trade and Commerce, Ottawa (refer File No. 1435). Particulars of the requirements, together with the date on which the tenders close at Melbourne, are briefly outlined thus:—

29031 — Sept. 15, 1915 — 81 (bogie) cast steel wheel centres.

29031 — Sept. 15, 1915 — 81 (leading and trailing) cast steel wheel centres.

29031 — Sept. 15, 1915 — 41 (driving) cast steel wheel centres.

29031—Sept. 15, 1915—10,000 (van and truck) cast steel wheel centres as per drawings.

The departure of the mails from San Francisco and Vancouver are as follows:—From San Francisco August 18, due Melbourne September 15.

Metals.

General weakness prevails in the metal market this week, antimony being the only metal showing any strength. Tin, copper and spelter have all declined, due to a light demand, while the lead market is stagnant for the same reason. Considering the heavy consumption of copper at the present time, the weakness in the market is rather surprising, but as soon as confidence is restored the market should recover. Solders are all lower on account of the decline in tin. The situation in regard to aluminum is unchanged, supplies are scarce and quotations are nominal. Business locally continues good, the demand for metals for munitions forming the greater proportion of this.

Tin—The tin market continues to decline on account of light demand, this encouraging uncovered buyers to keep out of the market except for absolute requirements. The recent small demand is chiefly caused by the majority of buyers receiving tin on old contracts. Tin has declined 1c locally and is quoted at 44c per pound.

Copper—The market is weak with no improvement in demand. The weakness is perhaps due to the high prices having caused the production to increase to a larger degree than the demand. It is also suggested that the restriction in buying is due to the fact that several concerns who accepted large war orders have not got their plants in operation as soon as was expected. The copper situation is, however, strong, owing to very heavy consumption and the market cannot help but recover. Copper has declined ½c and is quoted at 21c per pound.

Spelter—The situation continues much the same, but the market is weak and lower. The demand has fallen off and some of the producers who had been holding for higher prices appear to be now willing to accept less. The scarcity, however, continues and with a better demand the market would no doubt recover. Local quotations have declined 3c and are nominal at 25c per pound.

Lead—The market is stagnant with a weak undertone. There is a falling off in demand and lead is being offered at a figure below the "Trust" price. Local quotations are unchanged at 7¼c per pound.

Antimony—Although antimony is dull there is a very firm tone in the market. Consumption of the metal is almost entirely limited now to the provision of war requirements which are more likely to increase than diminish. Quotations are unchanged and nominal at 40c per pound.

Aluminum—The market is strong and the situation unchanged. Supplies continue scarce and quotations nominal at 40c per pound.

NEWFOUNDLAND TRADE.

THE transfer to the United States and Canada of a large amount of the trade ordinarily carried on between Newfoundland and Great Britain is one of the results of the war. This arises from the changes in the shipping situation.

The gradual withdrawal of trans-Atlantic steamers from the port of St.

John's because of the transport needs of the British Admiralty and the requirements of British trade has reached a point where only three small steamers are now plying between St. John's and Liverpool. These are freight vessels of the Furness Line, with practically no passenger accommodation.

The latest reduction in the service is the taking off of the Allan Line steamers, which for nearly fifty years have plied between Glasgow, St. John's, Halifax and Philadelphia. These ships, the Mongolian, Carthaginian, Pomeranian and Sardinian, are to be transfered to the route between Montreal and British ports.

Business men have necessarily made new connections in Canada and the United States, and steamers making weekly trips between St. John's, Halifax and New York are laden to the hatches.

BY SEA FROM B.C. TO HUDSON'S BAY.

A NEW chapter in Canadian history has been opened in the successful shipping of a cargo of Douglas fir from British Columbia to Hudson Bay, via the Panama Canal. The timber, which is to be used in the construction of piers and docks at Port Nelson, was sold to the Department of Railways and Canals by Hugh A. Rose, representative of the Canadian Western Lumber Co. A further consignment of lumber is on the way to the Polson Ironworks, Toronto, to be made into masts for a dredge which is being built for use at Port Nelson. Hitherto the lumber used at Hudson Bay has been southern pine from the United States. The cargo was carried by the Government steamer Durley Chine, which was the first boat to carry Douglas fir from one Canadian port to another.

WINDSOR A NOR. NAV. CO. TERMINAL.

THE importance of Windsor, Ont., as a lake port was made further evident on July 22 by the announcement of H. H. Gildersleeve, General Manager of the Northern Navigation Company, that, beginning immediately Windsor and Detroit would become the southern terminal for the company's steamers Noronic, Huronic and Hamonic, which make weekly trips to the Soo, Port Arthur, Fort William and Duluth.

The change of the southern terminal from Sarnia to Detroit and Windsor was brought about by the activities of the Windsor Board of Trade. General Manager Gildersleeve was reached in Montreal where he had gone to make arrangeemnts with Grand Trunk Railroad officials for the use of the Brush street wharf in Detroit. He said the company's steamers would start from Detroit, and after crossing to Windsor would start on their voyages to the north.

ONTARIO'S NICKEL COMMISSION.

FOLLOWING a prolonged controversy arising out of certain charges that nickel from Ontario mines was finding its way through various channels to Germany since the outbreak of hostilities in Europe, the Provincial Government a few days ago, through the Hon. Howard Ferguson, Minister of Forests and Mines, announced the appointment of the following Commission:

George T. Holloway, London, Eng., Chairman.

Willet G. Miller, Provincial Geologist, Toronto.

McGregor Young, K.C., Toronto.

Thomas W. Gibson, Deputy Minister of Mines, Toronto, Secretary.

The Commission is empowered to inquire into the whole nickel situation in Ontario with a view to establishing in the Province an industry that will have the material under observation from the time it leaves the mines to the time it is marketed.

While assurances have been given to the Imperial authorities and the Dominion and Provincial Governments that not an ounce of Ontario's nickel is finding its way into the enemy's hands, Hon. Mr. Ferguson states that the Provincial Government views the situation from a larger standpoint and has instructed the new Commission to ascertain whether it is not possible to complete the refining of nickel ore from the mines of Ontario entirely within the Province without having to ship it to American refineries.

The question of the province receiving an adequate return from its nickel deposits is regarded as of much importance, and on this point the Commission will also advise the Government.

CANADIAN GOVERNMENT PURCHASING COMMISSION.

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George Gault, Winnipeg; Henry Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

ALLIES PURCHASING AGENTS.

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:—

International Purchasing Commission, India House, Kingsway, London, Eng.

British.—Col. A. G. Barton and F. W. Stobart, Ritz Carlton Hotel, Montreal.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendance Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminister, London.

Russian.—Messrs. S. Ruperti and Aieksieff, care Military Attache, Russian Embassy, Washington, D.C.

PRINCE RUPERT DRY DOCK.

THE big dry dock at Prince Rupert, constructed by the Grand Trunk Pacific Railway in conjunction with the Dominion Government, is expected to be ready for service by August 1st. The dock, which has cost $2,500,000, consists of three units, with a total capacity of 20,000 tons. There will be two end sections of 5,000 tons each, and a middle section capable of accommodating a 10,000-ton vessel. All the units are interchangeable, and each dock is complete in itself, with pumps and air compressors. By employing the three sections together a 600-ft. steamer can be dealt with.

In addition to the actual dock there are five other features of the plant, namely, the foundry, which will be able to make castings as heavy as 12 tons; a boiler shop for marine repairs as well as for the construction of boilers; a machine shop; a ship shed and carpenters' shop; and a power-house equipped with two large turbo-generators and a 1,500 cu. ft. per min. air compressor. Construction work in connection with the dry dock and its accompanying plant has been under way since the beginning of 1912.

ZINC SITUATION IN CANADA.

THAT there is a scarcity of zinc in Canada is evidenced by the price to which it has advanced, from six cents a pound at the outbreak of the war to from 22 to 25 cents a pound to-day. Copper, the other metal which forms one of the elements of brass, has advanced from only 15 cents a pound to 20 cents a pound. Yellow brass, although better for shell purposes, is not as high-grade as the red brass, and yet, owing to the advanced price of zinc, it is now dearer. Yellow brass contains about 60 per cent. copper and 40 per cent. zinc, with a trifle of lead, and the red brass about 80 to 90

per cent. copper and 10 to 20 per cent. zinc, with a small portion of tin.

The scarcity of zinc is attributed by the manager of one of the firms manufacturing shells as being due to speculation, and he is of the opinion that the supply is now becoming more plentiful. The war breaking out, he believed, caused to a great extent a cornering of the market.

"The high price of zinc has been caused by a scarcity," said the manager of another firm. "There is no denying that, because the United States has been exporting great quantities of it to Europe ever since the war broke out. Before the war Europe was a large exporter of zinc, and despite the duty, Belgium and Germany were able to place their zinc in the United States and compete with the manufactured product in that country."

Owing to the fact that it was never really a paying proposition to mine zinc in Canada, he was asked about mining it now in Canada in order to furnish a supply to meet the demand, but he said that the zinc ore in Canada was of a poor quality. It was coarse and contained many impurities so that he questioned if the establishment of refineries in Canada would produce the quality of zinc out of the ores needed for the manufacture of shells. It was his opinion that before six months zinc would go up to 50 cents a pound.

Trade Gossip

Canada's Trade Balance.—The effect of war munitions exports is being shown in the fact that Canada is now building up a favorable trade balance from month to month. In June the excess of exports over imports was $11,716,000, in May $7,689,678, and in April $300,000, a favorable balance for the quarter of $19,705,678. In the previous quarter there was an adverse balance against this country of about $5,000,000. With the prospect for a heavy balance on the right side this fall, owing to the record crop promised, the outlook in this respect is distinctly favorable.

Steel of Canada Outlook.—In circles close to the Steel Company of Canada, the greatest satisfaction is expressed over the outlook. The company had to take some losses in the first quarter of the calendar year, but these have long since been made up, and it is predicted that the results of this year will be fully up to those of 1913, when the company enjoyed a profitable period. The corporation is turning out 200 tons of finished steel product per day, and this presumably will be increased as soon as the new open hearth steel furnace is finished.

Principles of Laying—Off Cylindrical Intersections---I.

By J. W. Ross

The more or less special nature of the work involved in the making of sheet metal piping has caused many manufacturers to avoid this class of work, with the result that when a job has to be handled, there is frequently considerable unnecessary loss incurred through errors in laying off material. The examples treated by the writer of this article should form a valuable reference to many manufacturers on ordinary as well as special occasions.

THE perspective drawing in Fig. 1 illustrates the intersection of two cylinders of equal diameter. The method of obtaining the mitre line, which is essential to the development of the patterns, is shown in Fig. 2 and 3.

Construction.

To construct this tee, measure off in Fig. 2, H G equal to $2\frac{1}{2}$ inches. At right angles to this line, make H A and G F equal to the diameter of the cylinder, which is 1 inch. Draw the line A B E F parallel and equal to H G. Measure off A B and E F each equal to $\frac{3}{4}$ inch, thus locating the diameter B E, of the intersecting pipe, which is equal to one inch. Raise the perpendiculars B C and E D equal to $\frac{3}{4}$ inch each. Connect C to D, thus completing the elevation view of the "tee" as shown in Fig. 2. To delineate the mitre line, it will be necessary to construct an end elevation view, as shown by Fig. 3.

At a suitable distance from Fig. 2 draw in the centre line G^1 7, Fig. 3, parallel to the line D E, Fig. 2. The points 7^2 G^1, Fig. 3, are located by prolonging the lines A F and H G, Fig 2. With centre X and radius X G^1, Fig. 3, strike the circle 4^2 7^2 10^2 G^2. Draw the line 4^1 10^1, Fig. 3, equal in length, and in line with C D, Fig. 2. Draw the lines 4^1 4^2 and 10^1 10^2, Fig. 3, parallel to the centre line 7^1 G^1. This completes the end elevation view. Project and describe—in a suitable position—the whole plan view, 1 4 7 10, above the cylinder elevation C B E D, Fig. 2. Divide this plan view into a suitable number of equal parts, as shown by the 12 divisions in Fig. 2. From these points draw projection lines —parallel to C B and D E—through the line A F. In Fig. 3 also draw a plan view in its correct relation to the cylinder and divide this into the same number of equal parts as was done in the case of Fig. 2. Project these points—parallel with the centre line 7 G^1—to their intersection of the cylinder 4^2 7^2 10^2 G^2. In Fig. 2 the plan view is numbered from 1 to 12. Similarly the intersecting points of the projection lines are numbered in relation to these numbered points in the plan view. Fig. 3 must also be numbered in relation to Fig. 2. As the view in Fig. 3 is shown by a quarter turn to that of Fig. 2, therefore 1 as shown in Fig. 2 of the plan view will be shown by 1 on the centre line 7 G^1, Fig. 3. The other points being numbered accordingly and in relation to both Figs. 2 and 3. The intersecting points are also numbered in respect to their positions.

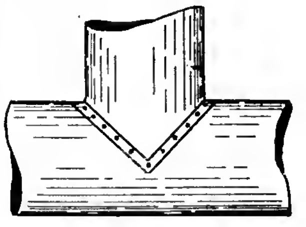

FIG. 1.

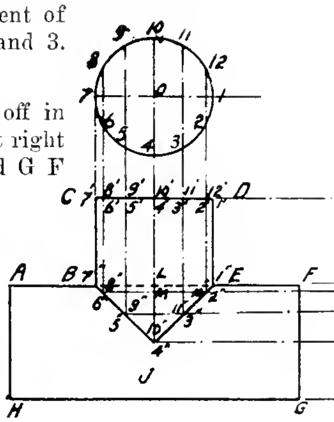

FIG. 2.

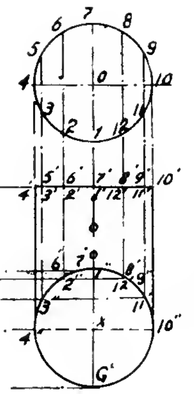

FIG. 3.

The points 4^2 and 10^2, Fig. 3, are projected over to Fig. 2 by drawing a line parallel to the line H G. Where this projection line 4^2 10^2, Fig. 2, intersects the vertical projection line 4^1 4^2, 10^1 10^2, Fig. 2, this locates the extreme point of the mitre line as shown by the letter J and the numbers 4^2 10^2, Fig. 2. Also by drawing lines parallel to J X project over the points 3^2 5^2 6^2 7^2 etc., from Fig. 3 to their intersection of their similarly numbered vertical projection lines in Fig. 2, thus locating the points 7^2 8^2 6^2 etc., Fig. 2. Connect all these points, thus defining the mitre line. Now having obtained the mitre line, the two intersecting pipes may be developed. The straight line D C D, Fig. 4, is made equal in length to the circumference of the cylinder of which D C, Fig. 2, is the diameter. C D, Fig. 2, equals 1 inch, therefore the stretched-out circumference D C D will equal 1 inch multiplied 3.14 = 3.14 inches, which is slightly over $3\frac{1}{8}$ inches.

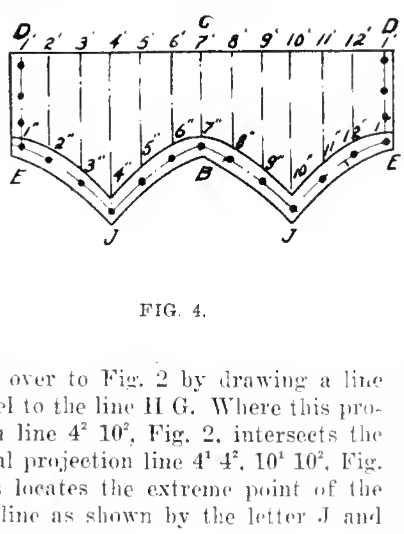

FIG. 4.

Divide D C D, Fig. 4, into the same number of equal parts as in the plan views, Figs. 2 and 3, which is 12. Number these points in consecutive order, with the idea in mind of having the vertical seam to come on the line 1^1 1^2, Figs. 2 and 3. Project lines downward from these points at right angles to D C D, Fig. 4 with the trammels or dividers set at a length equal to 1^1, 1^2, Fig. 3, transfer over to 1^1, 1^2, Fig. 4, this line being the vertical rivet line for this pipe, therefore this distance will be marked off on the extreme division points of the line D C D Fig. 4, as 1^1, 1^2 and 1^1 1^2. Reset the dividers to the distance 2^1 2^2, 6^1 6^2, 8^1 8^2, 12^1 12^2 Fig. 3 which are all equal in this case, and transfer over to their proper positions in Fig. 4.

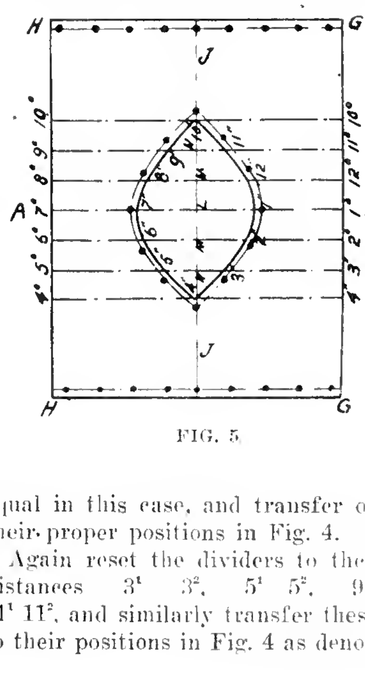

FIG. 5.

Again reset the dividers to the equal distances 3^1 3^2, 5^1 5^2, 9^1 9^2, 11^1 11^2, and similarly transfer these over to their positions in Fig. 4 as denoted by

*Note: The reference letters and numerals in the text, i.e., G^2, 7^2, etc., correspond with those of the illustrations indicated as G'', 7'', etc.

their respective numbers. A fair curve drawn through these located points will denote the mitre line. This mitre line is the flange line for light riveted plate.

The riveted line and laps being afterwards added according to the thickness of the plate and the size of the rivets.

If this tee is made of tin, to be soldered, then the mitre line will be the junction line of the two pipes, soldering

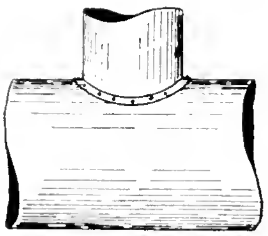

FIG. 6.

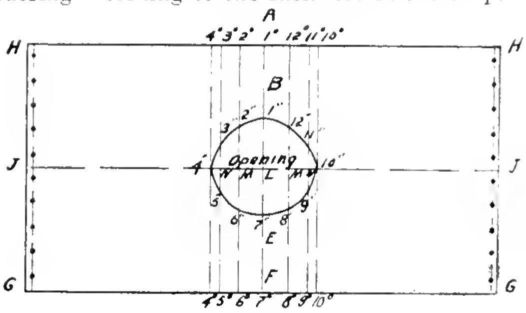

FIG. 10.

allowances to be added as required. Fig. 4 shows the completed templet for a riveted connection. To develop the cylinder H, A, B, E, F, G, Fig. 2 calculate the stretchout of which F G is the diameter. F G equals 1 inch, the stretchout will therefore equal 1×3.14 equal to a little more than 3⅛ inches.

Measure off G G Fig. 5 equal to 3⅛ inches. Draw H H parallel and equal to G G and the distance apart H G equal to the length of the pipe which is 2½ inches as measured by the length A F or H G, Fig. 2. As the pipe A F G H, Fig. 2 is a right cylinder, so will the outline H H G G be a perfect rectangle, that is to say its opposite sides being parallel and its angles right angles. This plate may be squared up by the process as explained in an earlier article of this series.

Bisect G G at F, Fig. 5, erect the perpendicular F A. Measure along the curve the distance 7^2 6^2. Fig. 3 transfer this over to 7^0 6^0 Fig. 5. Again take the length 6^2 5^2—along the curve—Fig. 3 and transfer over to Fig. 5 as 6^0 5^0. Also transfer the distance 5^2 4^2 Fig. 3 to 5^0 4^0 Fig. 5. Similarly make the distances 7^0 8^0, 8^0 9^0, 9^0 10^0. Fig. 5 equal, to their distances as denoted by their respective numbers in Fig. 3. Erect perpendiculars from these points to the line H H and number as shown. Bisect H G at J and draw in the line J J. Fig. 5. Set the dividers to the distance LI^2, Fig. 2 and transfer over to LI^2 Fig. 5. Reset the dividers to $M2^2$ Fig. 2 and again transfer to Fig. 5 as $M2^2$. Make $N3^2$ Fig. 5 equal to $N3^2$ Fig. 2. Similarly transfer over the remaining distances in Fig. 2 to their corresponding numbers in Fig. 3. An even curve drawn through these located points, will define the mitre line or the opening in this pipe. The rivet lines and hole centers are drawn in according to requirements. Fig. 4 shows the rivet holes to connect to the corresponding rivet holes in Fig. 5. It is extremely difficult to have these holes come fair, after rolling up and fitting together of the pipes, due to errors of workmanship in flanging and rolling. Generally one or the other is left blank regarding holes. The pieces being fitted together, marked off and then drilled or punched as the case may be according to the facilities of the shop. The general practice for light work is to put the holes in the vertical piece before rolling, then fit it to the horizontal pipe, afterwards drilling the holes through. In heavy work the holes are put in the pipe with the opening also before rolling, and the vertical piece is then fitted on, marked off and then punched. Fig. 5 shows the completed templet for the horizontal pipe shown in the perspective view Fig. 1.

Intersections of Unequal Diameters.

It will be observed that the mitre line is slightly different in the perspective view Fig. 6 than was in the preceding problem.

The side and end elevations are shown in Figs. 7 and 8 respectively. Measure off H G Fig. 7, 2½ inches long. H A is drawn at right angles to H G and is equal in length to the diameter of the large cylinder which is 1½ inches. Draw A F parallel and equal in length to the line H G. Bisect A F at L and raise the perpendicular 10, L, J. Measure L B and L E each equal to ½ inch, thus making the diameter B E of the small cylinder equal to 1 inch. Parallel to 10, J, draw the perpendiculars C B and D E each ¾ inch in length, connect C to D, completing the side elevation outline.

The plan view of the small cylinder is drawn above C D and divided into any number of equal spaces. It is desirable in order to facilitate the drawing of the construction lines and the developments, that the numbers of divisions be divisible by four, so that four quarters of the cylinder will be located with two of the points on the centre line vertically and two horizontally as shown in the plan views, Figs. 7 and 8. The number chosen here is 12, the four quarters being then each divided into three equal spaces. Number the points as shown. Project all points so numbered through A F and parallel to the centre line 10 J.

Project the axial line K K Fig. 7 to K^1 Fig. 8. With radius equal to K F Fig. 7, and centre K^1 Fig. 8, draw the circle in Fig. 8 representing the end view of the cylinder A F G H. Fig. 7. Draw the centre line 7 K^1 P Fig. 8 parallel to 10, J Fig. 7. Draw the line 4^1 10^1 Fig. 8 in line with and equal to CD Fig. 7. The outline of the vertical cylinder is completed by connecting 4^1 to 4^2 and 10^1 to 10^2, these lines being parallel to the centre line 7 K^1. Draw the plan view 1, 4, 7, 10, and number in relation to Fig. 7, keeping in mind that the plan view in Fig. 8 is turned one-quarter round to correspond with end view Fig. 8. Project all the points to the section of the cylinder J 7^2 J Fig. 8. Project these numbered points as 4^2, 5^2, 6^2 etc. Fig. 8 by straight and parallel lines till they intersect similarly numbered vertical lines in Fig. 7. A suitable curve drawn through these points in Fig. 7, defines the mitre line. D C D Fig. 9 equals 3⅛ inches, this being the calculated stretchout of the dia. C D Fig. 7. Divide D C D into 12 equal spaces numbered accordingly. Draw in the perpendiculars equal in length to the perpendiculars of C B J E D Fig. 7. A curve drawn

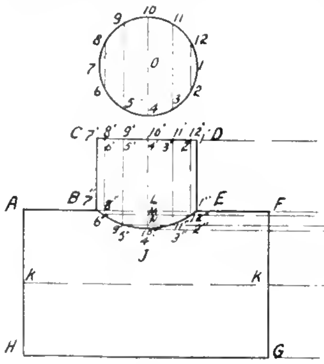

FIG. 7.

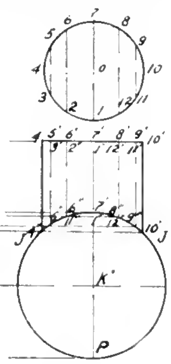

FIG. 8.

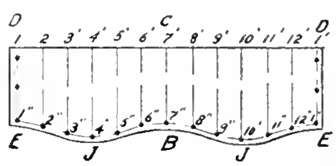

FIG. 9

through these located points will define the mitre line or flange line. The rivet line and lap, or seaming allowances being added accordingly. It will be noticed that the contour of the mitre line of this templet is slightly different to that of the templet Fig. 3 for the equal diameter cylinder intersections.

Measure off G, F, G, Fig. 10 equal to

the stretchout of the cylinder J, 7^2, J, P, Fig. 8 of which P 7^2 Fig. 8 or F G Fig. 7 is the diameter. This equals 1½ inches multiplied by 3.14 equals 4.71 or nearly 4¾ inches. Erect the perpendiculars G H, G H. Fig. 10 at right angles to G G, and equal in length to H G Fig. 7. Connect H to H which will be parallel and equal in length to G G.

Bisect G G at F and erect the perpendicular F, A. Measure 7^0, 6^0, 6^0, 5^0 5^0, 4^0, etc., Fig. 10 equal to the length measured along the curve of 7^2, 6^2, 6^2, 5^2, 5^2, 4^2, etc. Fig. 8. Erect vertical lines on these points as 4^0, 4^0, 5^0, 3^0, 6^0, 2^0, etc. Fig. 10. Bisect H G at J and drawn in the line J J.

Mark the intersection of line J J with line 1^0 7^0, with the letter L. Locate M and N in a similar manner. Now lay off the distances L, 1^2, L, 7^2, M, 12^2, M, 8^2, etc. Fig. 7 in their respective positions in Fig. 10. Draw in the curve defining the opening Fig. 10. Draw in the rivet line and space off the rivets. Space off the rivets at H G and add on the laps. This completes the templet.

Re-enforced Tee.

The perspective view Fig. 11 illustrates a tee pipe re-enforced by a shoulder collar, to resist vibratory strains, etc. Fig. 12 shows the side elevation, while the end elevation is shown by Fig. 13. To construct these views, measure off C D Fig. 12 equal to 3 inches, and A C and D B equal to the diameter of the cylinder—drawn at right angles to C D, and equal to 1 inch in length. Connect A B which is parallel to C D. Bisect A B at L and draw the perpendicular 10, J. Measure of L, 10^1, equal to 1 inch. At right angles to this line, through the point 10^1, measure off 10^1, 7^1, and 10^1, 1^1, each equal to ½ inch, making the diameter 7^1 1^1 of the vertical cylinder equal to 1 inch. Draw the lines 7^1 R and 1^1 R parallel to the centre line 10, J. Mark R, 1^0, R 1^2, R 7^2 and R 7^3 each equal to ½ inch. Connect the point 1^2, 1^3, and 7^2, 7^3. With centre O and radius equal to 4^1, 7^1, construct the plan view 1, 4, 7, 10, as seen through E F. Divide into 12 equal spaces, number and project the points down through E F. Number these also in relation to their position. Now construct the end elevation, Fig. 13. Bisect B D at K Fig. 12. Draw the line K Fig. 12 to K^1 Fig. 13 parallel to A B and C D Fig. 12. With K^1 Fig. 13 as centre and radius K B or K D Fig. 12, describe the circle P, 4^0, 1^0, 10^0. Draw the centre line K^1, 7, Fig. 13 parallel to the centre line 10, J, Fig. 12. Project the line E F Fig. 12 over to 4^1, 7^1, 10^1 Fig. 13. Draw 4^1, 4^0, and 10^1 10^0 parallel to the centre line K^1, 7, tangent to the circle 4^0, 1^0, 10^0, P^0, locating the points 4^0 and 10^0 on the line K K^1. With centre O Fig. 13 describe circle 1, 4, 7, 10, with a diameter equal to the diameter 4^1 10^1 of vertical cylinder. Divide this plan view into the same number of equal parts as the plan view Fig. 12. As this

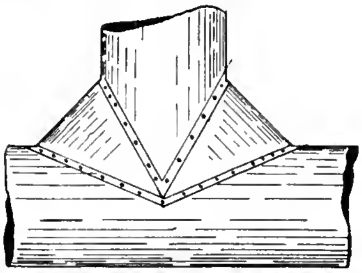

FIG. 11.

view Fig. 13 shows a quarter turn of the view in Fig. 12, the point 1 will commence on the centre line 7 K^1, the remaining points being numbered in their consecutive order in relation to the position of point 1.

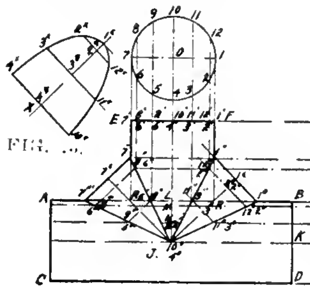

FIG. 12.

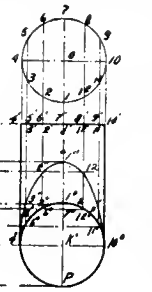

FIG. 13.

Project all these points down to the circle P, 4^0, 1^0, 10^0. Number their intersection accordingly. Project the points 4^0, 10^0, Fig. 13 over to their vertical projection in Fig. 12 thus locating the points 10^0, 4^0 at J, Fig. 12. Connect point J by straight lines with the points J, 1^2, J, 1^0, and J, 7^3, J, 7^2. These lines will define the mitre lines of the several pieces to be developed. From

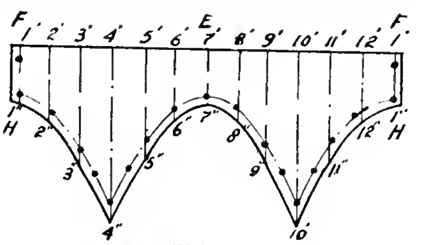

FIG. 14.

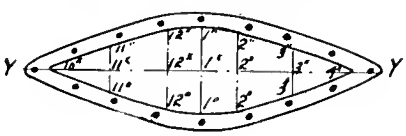

FIG. 16.

the points 1^0, 2^0, 3^0, 4^0, 5^0, etc., in Fig. 13, project over to the mitre lines 4^0 7^3, and 4^0 1^0, Fig. 12, locating points 1^0, 2^0, 3^0, 4^0, etc. Note where the vertical projectors intersect the mitre line 7^2, 10^2, and 10^2, 1^2. Number these points in respect to their vertical projectors, connect the points 2^2 to 2^0, 3^2 to 3^0, 6^2 to 6^3, 5^2 to 5^3, these lines being parallel to the lines 1^2, 1^0 and 7^2, 7^3. These points may be projected over to Fig. 13 to show the side elevation of the collar, but this is not essential for the development of any of the patterns. In fact the whole of the side elevation view need not have been drawn.

In this case it was done to demonstrate the method of solving the problem. A half section view drawn in the diameter B D, would have given all the information required. If there is any doubt in the minds of the readers regarding the construction it would be better to draw both views thus being enabled to grasp the subject more thoroughly. Further advancement in the practice of these problems, would necessitate more or less construction lines according to the class and character of the work. Fig. 14 shows the templet for the vertical piece in Fig. 12.

Calculate the stretchout of E F Fig. 12, and lay this out on the straight line F E F, Fig. 14. This length equals 1 × 3.14 or nearly 3⅛ inches. Divide F E F into 12 equal divisions. Through these points draw perpendiculars and number them according to the divisions and numbers of the plan view in Fig. 12. Take the distance 1^1, 1^2, and 7^1, 7^2, and transfer over to 1^1, 1^2 and 7^1, 7^2, Fig. 14. Set the dividers to the distances 2^1, 2^2, 3^1, 3^2, 4^1, 4^2, etc. Fig. 12 and transfer all these distances over to their respective locations in Fig. 14. Draw in an even curve through these points thus defining the mitre line. The connecting flanges being on the collars or gores, the rivet line instead of being added on to the mitre line, Fig. 14, will have to be drawn back towards the line F E F, to a distance suitable so that the mitre line will define the lap. Add the laps for the vertical seams at F H, F H. Then Fig. 14 will show the complete templet for vertical piece as shown in Fig. 12.

To develop the horizontal course Fig. 12, calculate the stretchout of the cylinder of which B D is the diameter. Measure this stretchout which equals 3⅛ inches along the line C A C Fig. 17. Draw D B D parallel and equal to C A C, and make D C, the distance apart equal to the length of the cylinder D C Fig. 12. The line D C is drawn at right angles to C A C. Bisect C A C to locate A. Raise the perpendicular A B to the line D B D. Measure off the distances 7 to 6, 6 to 5 and 5 to 4, etc. Fig. 17, equal to the distances 7^0 to 6^0, 6^0 to 5^0, 5° to 4°, etc. Fig. 13 measured along the curve. Erect perpendiculars through these points, parallel to the line A B. Now take the distances L, 1^0, and L 7^3, Fig. 12, transfer this over to L, 1^0, and L, 7^3, Fig. 17. Similarly transfer the distances M, 6^3, M, 2^0,

X, 5', X 3°, etc., Fig. 12 over to their corresponding numbers in Fig. 17. Draw in the curve to define the mitre line which is also the opening. Rivet line being afterwards drawn in according to the laps of the gore. To develop the gore it is necessary to show an end view of the centre gore line 1^x 4°, Fig. 12.

To construct this section, draw the line $X1^x$, Fig. 15 parallel to the line 4° 1^x Fig. 12. Transfer the distances 1^x, 2^x, 2^x, 3^x, 3^x, 4°. Fig. 12 to the distances 1^x, 2^y, 2^y, 3^y, 3^y, 4^y. Fig. 15 . It will be observed that the distance through the points 2^z, 12^z, is equal to the distance through the points 2^1 12^1, which is shown in the plan view 2 to 12 measured along the projector, Fig. 12. As both the intersecting cylinders are equal, the distance 12^o, 2^o, as shown by 2^o, 12^o in Fig. 13 is equal to 2, 12, Fig. 12. Take this distance and place half at each side of the point 2^y along the line drawn at right angles to $X1^x$, thus locating the points 2^x and 12^x Fig. 15. Make 3^x 3^y 11^x Fig. 15 equal to the straight line distance 3, 11, in plan view Fig. 12, thus defining the section distance through the points 3^z, 11^z, and 3^o, 11^o Fig. 12. Similarly transfer the distance 4, 0, 10, Fig. 12 to 4^x, Y^x, 10^x, Fig. 15. A fair curve drawn these points represents the section shown through the straight line 4° 1^x in Fig. 12. The stretchout of this curve is laid out on the line Y Y Fig. 16. It is divided up into the same distances as on the curve Fig. 15. Draw lines at right angles through these points.

Take the distances 1^x, 1^z, and 1^x, 1^o Fig. 12, and place this distance to locate the points 1^z and 1^o on the line 1^z, 1^x, 1^o Fig. 16. Again transfer the distances 2^x, 2^z, 2^x, 12^z, 2^x, 2^o, and 2^x, 12^o, Fig. 12 over to their similarly numbered positions in Fig. 16. Transfer the remaining measurements over to Fig. 16. Through these points draw a fair curve. This curve will be the mitre line and in this case also the flange line. Add on the rivet line and laps. Fig. 16 shows the complete templet for either of the two gores.

BOASTFULNESS.

THE art of advertising or of making known to those concerned the merits of what one has to sell varies in method according to the public to which the advertisements are addressed. When advertising pills it may do to state that they are worth a guinea a box, although sold at 27 cents, and in spite of the fact that everyone who reads the advertisement knows the statement to be untrue. The object of the advertiser is not to deceive the buyer as to the value of the pills, but to ensure, by the constant repetition of their name, in conjunction with a striking phrase that when pills are required his own make will naturally come to mind and be purchased. Advertising of this kind is very popular, and undoubtedly has a certain hypnotic value when selling anything whatever, but is not to be recommended when the intention of the advertiser is to instill confidence in the productions and in his advice as an expert.

The buyer of a machine tool depends to some extent on makers' advertisements for information, and such being the case he has a right to expect that they shall be reliable and free from boastfulness. Boastfulness is easily detected and destroys the confidence of the buyer, thus defeating its own ends. Examples of this kind of advertising can be seen in most of our technical journals. One maker advertises "Perfection in Design," which we know has not yet been attained anywhere. Another that the teeth of his milling cutters being large are therefore exceptionally strong—which does not by any means

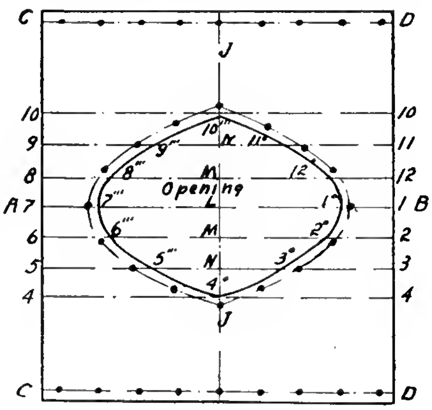

FIG. 17.

follow. The way to make teeth strong is to make them thick, which was not done in the case in question, as the illustration accompanying the advertisement clearly showed.

A third illustrates an article 28 feet in diameter, weighing 90,000 lbs., stated to be "True to one-thousandth of an inch," which, if a statement of fact, can only be so under very restricted conditions of position and temperature, and is probably quite necessary.

Such statements convey an impression of boastfulness in style, which is only too often accompanied by inferiority in matter.

Bold and striking statements are by no means inadmissible in engineering advertisements, providing they are true and capable of proof or of demonstration, but it is nevertheless wise that they should contain a little less rather than a little more than the truth.—Herbert's Monthly.

Hamilton, Ont.—The Hamilton Machine Gun fund now totals $105,000 and contributions continue to come in steadily.

TUNGSTEN.

TUNGSTEN is one of the many raw materials, the value of which has been greatly enhanced as a result of the war. It is a most important ingredient of high-speed steel, and the increased demand for that product itself, rendered necessary by shell manufacture, would be sufficient to cause a large advance in price. While most of the tungsten hitherto used in Britain has had to be imported, it is good to know that this metal is now being prepared from raw material obtained in the County of Cornwall, England.

Although most of the tungsten produced by different countries is used in steel making, considerable quantities are required in the manufacture of incandescent electric lamps. The material as received by the lamp makers is in a powdered state, and the Society of Engineers (London) recently had an opportunity of seeing it being made into the thread-like wire so familiar to all users of electricity. The tungsten powder is compressed into small bars by hydraulic pressure, and is afterwards purified at a very high temperature by a hydrogen flame.

After being treated with electricity to increase the solidity, it is gradually swaged down at a high heat, till it is small enough to be drawn through dies in the ordinary wire drawing manner.

PROPOSED MUNITIONS FACTORY FOR "AMATEURS."

MUCH interest is being taken in North-East Coast shipyards and engine works in the proposed establishment for the making of munitions of war by technical and unskilled part-time workers.

The proposal is that a munitions factory should be established in Newcastle, the capital to be found by the Government, as was the case in connection with the Leeds munitions factory. The promoters aim at a small factory as a beginning, which should have twenty lathes, and would cost about $25,000. There will be no difficulty, it is understood, in obtaining lathes, and suitable buildings can be secured. The labor will be provided by part-time men of skilled occupations, such as draughtsmen and others who have served an apprenticeship to technical trades, while quite a number of commercial men will be available who are fair mechanics. A few permanent officials will of course be required.

The proposal seems eminently practicable, and, since the need exists for taking advantage of both large and small offers of assistance in munition-making, it is likely that the Government will make use in some form of the proposal.

PRODUCTION METHODS AND DEVICES

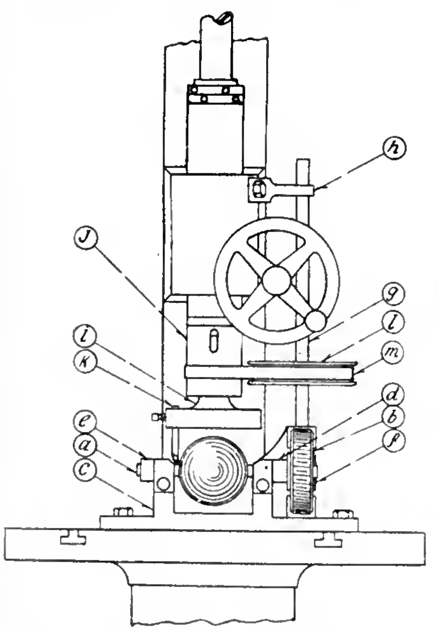
A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

BALL TURNING ON A DRILL PRESS

By J. W. Innes.

THE accompanying sketch illustrates the method adopted in a shop some time ago for the manufacture of a quantity of small brass balls used in the construction of a certain make of check valve. While no high degree of accuracy was required the balls were necessary to be approximately round. To produce these in fairly large numbers was a problem that the foreman had to solve. There being no suitable device in the shop with which to accomplish the required result, the fixture here shown was designed and used with very much satisfaction, both in quantity and quality of production.

The finished balls were of 2 in. dia. A small hole ½ in. dia. was drilled through the centre of the rough casting. It was then driven on the arbor (a). On one end of this arbor was secured the worm gear (b). The arbor was then placed in the jig (c) (which was secured to the drill table with the ball in a central position) and held in position by the collars (d) and (e). The worm (f) was secured to the shaft (g) which passed through and revolved in the bearings of the jig (c) and bracket (h). The shank of the tool-holder (l) was



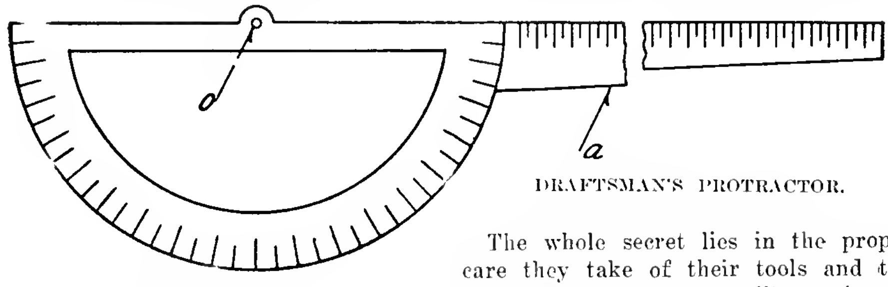
BALL TURNING ON A DRILL PRESS.

turned to fit the drill spindle (j) and the tool (k) was made to suit the work in hand and secured by the set screw shown. Secured to the shaft (g) was the flanged pulley (l), which was driven from the drill spindle by the belt (m).

The operation was as follows: After jig and tool-holder were properly set and secured, the drill spindle was lowered until the tool came to the proper position. The spindle then being secured in this position, the action of the mechanism caused the ball and arbor to revolve and thereby remove the metal.

After removing the ball from the arbor, the hole in the centre was closed, the construction of the valve preventing the plug from coming in contact with the valve seat.

The work produced from this fixture was highly satisfactory and well repaid the expense of the construction.



DRAFTSMAN'S PROTRACTOR.

DRAUGHTMAN'S PROTRACTOR.

By J. Garth.

THE sketch herewith shows the design of a protractor which extends the usefulness of those ordinarly seen on the draughtsman's table. The feature of this design is the extended arm (a) and the small centre hole (o). By means of this small hole a fine point can be inserted through the protractor and into the intersection of the two lines which form the required angle. By revolving the arm (A) about the centre (O) any desired angle is readily obtained.

CARE OF THREADING DIES AND PIPE CUTTING TOOLS.

By P. W. Blair.

OWING to the universal use of dies for the cutting of screw threads on pipes and rods they should receive far more and better attention than is commonly accorded them.

The proper care of the dies and lubrication of same when in use is one of the greatest factors of economy that has to do with their use, and the cutting of screw threads has become one of the most important parts of nearly every line of manufacture of metal products.

In some cases the greatest limits of accuracy are required in the production of threaded parts and it is often remarked by users of stocks and dies, "How is it that I cannot cut so accurate and smooth threads as are on some of the fittings or bolts I have just purchased?"

The whole secret lies in the proper care they take of their tools and the lubricant used. As an illustration, a screw thread may be satisfactory if the parts merely have spiral marks which can be forced into a tapped hole and once in place it is out of sight and may never be discovered, consequently in some instances almost any kind of a thread will pass.

There are, of course, all sorts and conditions, but it seldom requires as much time to produce a perfect thread as it does the other kind, and the good thread can be produced with far less wear and tear on the tools.

If a man becomes sick he usually calls a physician and has his trouble diagnosed and suitable remedies applies. He rarely ever applies the same methods to his business. If a tool goes wrong and does not operate satisfactory he does not spend much time trying to discover the cause of the trouble. If the trouble cannot be removed by the first application of his "remedies," the tool in many cases is condemned as being no good anyway, and he may also have something to say to the maker of such a tool.

In applying a lubricant for the cutting of pipe, bolt and other screw threads, similar results may be arrived at. Some users seem to thing that any kind of a lubricant can be used; consequently an oil of some kind is used but seldom with proper regard, if any, as to whether the oil is suitable for the purpose. One of the most desirable features of screw cutting is to obtain the greatest quantity and quality of the work with the least wear and tear upon the dies.

It does not follow that because you have been using a poor grade of oil with fairly good results, that the same will be obtained when a new shipment of pipes or rods requires threading. The quality of the stock may vary to such

an extent that a different grade of lubricant is almost necessary.

Many users of thread cutting dies may still maintain that a tool that will cut a good thread with one grade of oil should give satisfaction used with any oil. Not only should suitable lubricants be used for various grades of metals but also in the cutting of different metals.

Many large manufacturers carry quite a number of different oils and lubricants, and are still experimenting to obtain better results.

All stocks and dies when not in use should be kept in a suitable place and thoroughly cleaned of foreign substances, so that when they are again required they shall be in good condition.

SIMPLICITY IN TOOL DESIGN.

SIMPLICITY in tool design may sometimes be more apparent than real, and elaboration in the right direction often results in real economies. Most people familiar with the principles of tool design realize this, but too often one sees designs which are the outcome of a short-sighted view. As an instance, we may consider the machining of a large bevel gear, such as is used in motor car differentials. This would be made from a steel stamping, and two variant methods of machining on automatic turning machines are commonly seen, one bad, and the other good.

In the first method, the large bevel face is attacked with a roughing cutter in the form of a broad serrated flat blade, which is followed by a similar finishing cutter not serrated. This looks "simple" and turns out the work rapidly for a short time, but the hard scale soon plays havoc with the serrated roughing tool, and when it requires grinding it has to be returned to the tool room, being too difficult a job for the operator to tackle.

In the second method, one sees the bevel face traversed by a single point tool carried on a slide mounted on the

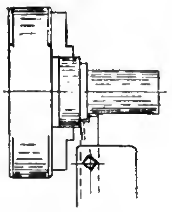


FIG. 1.

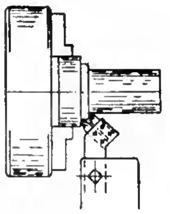

FIG. 2.

SIMPLICITY IN TOOL DESIGN.

cross slide, and actuated by a suitable former cam. The actual cutter is only a small piece of rectangular high-speed steel, which can be quickly made and reground by the operator himself. The initial cost of the latter arrangement is certainly the greater, but there is no question as to which is ultimately the better.

On another job, one finds two shoulders close together that have been faced from the cross slide. A bad method employs a facing tool with a step ground on it, the same width as the distance between the shoulders (Fig. 1). This again is "simple," and works well until one of the cutting points gives out, when again re-grinding is a tool-room job.

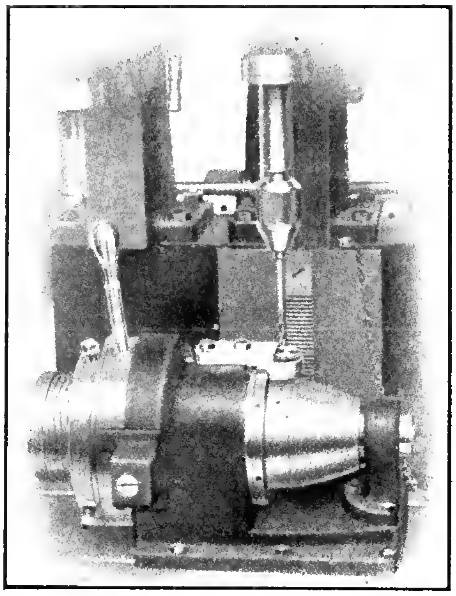
The better method (Fig. 2) utilizes a small tool holder carried in the cross slide tool block, the cutting tools being two small pieces of steel which can be set the correct distance apart. These, again, are easy to re-grind, and cheap to replace, although the initial cost is the greater of the two.

Many similar instances could be cited, but enough has been said to show that the initial cost is not the last cost, and the best designs utilize cutting tools in the simplest possible form, which can be re-ground and, if possible, made by the operator himself.

DRILL JIG FOR SHRAPNEL SHELLS.

THE noses of the larger shrapnel shells are made separate from the bodies, and are held in place by a number of pins and screws. When the charge in the base is exploded, the screws are sheared and the head blows off, allowing the bullets to scatter.

On the 60-pounder shell there are eight screws and eight pins, the holes for which are drilled and tapped with the head and body assembled. The illustration shows a type of jig used in conjunction with a ball-bearing drill which has given much satisfaction wherever employed. The jig is semi-automatic in its action, and consists of a casting bored to receive a sleeve in which the shell is clamped, while at the right-hand end a small bracket and locating plug support the nose.



DRILL JIG FOR SHRAPNEL SHELLS.

When the operator pulls the handle towards him, the locking bolt is withdrawn, and on pushing it back, the sleeve carrying the shell rotates until the bolt drops in again. This jig is exceedingly rapid in action, and the whole arrangement very compact.—Herbert's Monthly.

GUNS v. TORPEDOES.

BEFORE the war started the gun was generally looked upon as the most effective weapon, but the success of submarines in the early stages of the war probably altered the balance of opinion. In making a comparison, it must be remembered that recent naval warfare has favored the use of the torpedo and given little chance to the gun. If the torpedo is to be a success at all it must be used at short ranges, and, generally speaking, the submarine is the only vessel which renders this possible.

In naval battles fought before the advent of the submarine the percentage of hits with torpedoes was notoriously small. On ships stationary it was somewhat more successful, but very few vessels in motion were destroyed by torpedo attack. The destructive power of the torpedo, should it get home, is unquestionable, but its small speed compared with that of a shell is its great drawback.

The maximum velocity of a torpedo is not more than 45 knots, and this is reduced as the distance covered increases. Even the modern torpedo takes nearly three minutes to cover two miles, and in this time the relative speeds and courses of the passing vessels may be entirely altered, and large surface vessels would not approach one another so closely unless gun-fire had already done its work. It is only when used in a submarine that the torpedo is effective, and only then when the presence of the underwater vessel is undetected.

In the few naval engagements that have been fought in the North Sea, where it would be reasonable to assume that submarines would be valuable, their success has been nil, and the inference is that high speeds and good manoeuvring are all-sufficient to destroy the aim of the torpedo officer. Taking vessels destroyed during the war, slightly more have been destroyed by gun-fire than by torpedoes from submarines. The few isolated cases where surface craft have successfully launched torpedoes are quite special and cannot be taken as precedents. It can safely be predicted that when the big ship actions come, the victory will be obtained by gun-fire and gun-fire alone, and it is to these actions that the British Navy looks forward with every confidence—L.J.C.

HEALTH HAZARDS AND SAFETY PRECAUTIONS.

By J. M. W.

A STUDY of recent developments of applied science show that the first applications of many new inventions have been characterized by great indifference to their effect on operators. The complete success of oxy-acetylene welding and similar processes has been accompanied if not made possible by suitable precautions to safeguard the health and comfort of the men engaged on the work.

Oxy-Acetylene Welding.

The adoption of oxy-acetylene welding has been so rapid, and the different branches of industry which offered suitable opportunities for its use so numerous, that the trade obtained a wide field of activity before manufacturers obtained a true appreciation of its attendant hazards.

The type of apparatus varies considerably with the nature of the work. Small portable repair outfits are noteworthy principally because the gases are contained under pressure in storage cylinders. Fixed plants such as are used in shops specialising on welding consist of an acetylene gas generator which supplies this gas under a suitable pressure. The oxygen is usually obtained in cylinders from firms which specialize in the manufacture of this gas.

When using both gases from cylinders the cylinders are fitted with valves so as to maintain the supply of gases at the proper pressure. These valves are automatic in action and reduce to a minimium the risk and attention required from the operator.

Portable generators are not desirable on account of the necessity when traveling, for removing the water and carbide. Any carelessnes in this respect may allow sufficient quantities of carbide to come in contact with damp or moisture and generate enough gas to cause a severe explosion. Additional care and common sense must be exercised when handling generator plants as compared with storage cylinders.

Cleaning Out the Gas Generator.

The use of an open flame light when cleaning out a generator is a fruitful source of accident. When starting to clean a generator, the gas may be released through a suitable exit until the pressure gauge falls to zero. But the fact that the gauge is at zero does not mean that there is no gas inside. It means that the gas which is inside is at zero pressure, and unless that remaining volume of gas has been displaced or allowed to pass out, so that the space which it occupied is filled with air, it will still be in the apparatus waiting for the first opportunty to ignite. When the generator has been safely opened, any remaining water which has not been completely drained off should be carefully mopped up and all traces of dampness removed before cleaning out the carbide. Especially is this the case where the construction of the generator is such that the carbide may cake and remain on the walls, as lumps of this caked carbide may be capable of generating a dangerous quantity of gas should they come in contact with unexpected moisture.

These considerations will make quite apparent the criminal negligence which accompanies the use of an open flame light around a generator at any time. A portable incandescent electric lamp is the only source of illumination which should be legally permitted.

Welding Apparatus Perfection.

The welding apparatus proper—blowpipe, torch, etc.—has been brought to a very high state of perfection by the various makers, and all the details such as control valves, flexible piping, etc., are capable of satisfactory service for long periods. In spite of care, couplings will become loose, careless workmen may burn holes in hose pipe, etc., and these defects are not readily detected because of the all pervading odor of acetylene gas which is an almost unavoidable feature of all plants. An accumulation of such small leakages may have disastrous consequences to the operator.

Hazards resulting from the foregoing conditions are of an active nature and their results are rapid and evident.

Hazards of a passive, but not less certain and detrimental nature are those which affect the operator physically and continually.

The most attractive feature of gas welding is the intensely strong light which is given off by the flame. While an ignorant and stubborn operator may spurn the use of protecting glasses, the effect on the sight soon makes itself felt, so that for self protection alone the adoption of glasses is a matter which soon adjusts itself. Recent experiments with tinted lenses in efforts to obviate the blinding effect of automobile headlights, have brought about the use of amber colored glass which effectually removes the glare without obstructing the vision so much as the ordinary smoked lenses do.

In addition to having them of the most suitable tint, the lenses should be of substantial dimensions and firmly secured in a strong frame. The presence of foreign substances may cause sparks of molten metal to be thrown off the work, and occasional moisture causes spurting of the job which should be properly guarded against.

Constitutional Feature.

Lastly the effect of the work generally may be such that occasionally a particularly expert operator, through some constitutional weakness, may be incapacitated much more quickly than another operator less expert but more robust. One has merely to consider the intense heat of the flame to realize that metallic vapors are being given off by the work in close proximity to the operator's face. The products of combustion from the flame itself may well be detrimental to the health without the addition of fumes from copper, aluminum, zinc, etc. The use of a helmet such as is used by sand-blasters is the least protection that can be taken and if used along with a respirator may delay but not permanently prevent the results of continued occupation on welding work.

SPACING OF MACHINES A FACTOR OF SAFETY.

By R. James.

ONE of the causes of industrial accidents is the system—or lack of system—that prevails in many establishments of placing machines without regard to their particular production or the output of those in the immediate vicinity.

How often can one observe the apparently crowded condition of many shops, especially where want of space and need of extra tools almost demand these conditions.

Too often this is done with a view of economy, but very often this same apparent saving has been the cause of many accidents.

To produce satisfactory results from the operation of almost any machine, sufficient space must be left about the floor for the convenience of the operator and also for the product before and after the machining operations.

If this space is not available, the freedom of action of the operator, and therefore the output, must be restricted.

Where two or more machines are crowded together it prevents the operators from giving proper attention to their respective duties.

If the men are on a day rate system, and the movements of one in placing or removing work interferes with the other, the second operator, in many cases, must remain idle while the first performs his necessary task.

If the men are working on a piece work basis, the second man will continue his duties, often at the risk of injury to some portion of his body.

The writer has observed an operator turning a wooden pattern, at high speed, on an engine lathe, the face plate of which was directly in line with another man working a lathe a few feet away; suddenly, without any warning the tool lifts the pattern from the face plate and portions of the flying wood are projected at the man working opposite, fortunately missing him by a few inches.

Contracted Aisles.

Sometimes, owing to lack of sufficient space in the aisle between machines, when work must be carried from place to place, a slight slip or shove may cause a person to stumble, forcing him to put out his hand to protect himself from falling. This effort may cause his hand to come in contact with levers or moving mechanisms and the result is possibly an accident to himself or someone working close at hand.

Another source of trouble may result from the placing of machines, such as screw machines and hollow spindle lathes, etc., in positions where the projecting parts will cross an aisle or protrude in close proximity to a bench, where other workmen must pass, and often before a warning can be given, the clothes or flesh is badly torn.

A pile of castings or other material will sometimes be placed (perhaps temporarily) in a location where a workman is accustomed to perform his usual duties and is often the cause of injury.

Often, when an accident has happened the injured person must bear the blame, when in reality the local conditions are responsible.

Dust Feature.

The cause of many a short life machine can be traced to the locating of said machine too close to the flying dust and particles from an adjacent grinding machine. The dust from the continual grinding penetrates to all parts of the machine, and the movable parts receive a large supply of this destroying agent: the destruction is so gradual that when the fault is at last noticed the injury, in many cases is beyond repair, or when repaired is not satisfactory.

While the universal cry of "Safety First" is being advocated, any improvement in these conditions would be a step in the direction of advanced economy and increased production, as well as the bettering of the working conditions and moral responsibilities of employer and employee.

BRASS MIXTURES FOR PLUMBERS AND STEAMFITTERS.

By P. W. Blair.

THE wide variety of its application in commercial and artistic lines gives to the making of brass a scope unequalled by few metals. A mixture or alloy designed for any given purpose may be useless for any other purpose. Therefore, the mixture of the metal for any purpose of manufacture is of the most importance. The compound must be so prepared that it will fully meet the conditions under which the article manufactured will be used. Owing to the hard usages and wear that plumbing and steam brass goods are subjected to, and the constant pressure on same, manufacturers of the above lines are improving the quality and alloys of metals they use in the manufacture of this line of goods.

The leading concerns employ a metallurgist in their foundry and know how to mix their metals by analysis and practice by scientific melting in place of the rule and thumb method previously employed, and get results.

The leading authorities on brass goods differ on the question of what really makes the best mixture, but they are agreed that copper in excess of zinc produces the best grade of brass. Copper, however, has inherent defects as a metal which must be overcome by the judicious use of alloys.

Mixture for Good Results.

The following compound is recognized by the leading metallurgists to produce the best results for plumbing and steam brass goods:

Copper	85
Zinc	6
Lead	4
Tin	5
	100.

This produces what is known commercially as red brass, in contra-distinction to yellow brass, which contains less copper and more zinc, and is consequently a much less expensive metal, and which is also of more coarse grain metal and more brittle.

The mixture I have just given the above formula for, might with propriety be called a bronze composition, as it does not differ materially from the bronze formula given by Hirons, the English authority, which is:

Copper	84.0
Tin	2.9
Lead	4.8
Zinc	8.3
	100

Melting, Mixing and Casting.

The mode of melting, mixing and casting has an important bearing in the final result. In the manufacture of plumbing and steam brass goods from red brass, the constituent parts are, of course, of the utmost importance in forming the foundation of the goods, and play an important part in the final results. It must be taken into consideration, also that the mere mixing and casting of the metal would of itself fall short of producing a first-class metal, if it were not also for the particular process by which the metal is prepared in the furnace and the manner in which it is handled in the casting.

Red brass has many advantages compared to yellow brass in the manufacture of plumbing and steam brass goods.

It is much more pleasing to the eye.

There is an absence of the cheap brassy appearance of the goods which shows to a pronounced effect where zinc is used in large quantities.

It is more tenacious, closer grained, and tensile strength is far superior.

It is fibrous and more tenacious than yellow brass which by reason of the large percentage of zinc is a crystaline.

On this last point, Arthur H. Hirons, principal of the School of Metallurgy, Birmingham and Midland Institute says: "The pastiness of zinc manifests itself decidedly in alloys immediately below those which are fibrous, becoming more strongly marked as the alloys are rich in zinc. The fracture of these white alloys is for the most part vitreous, and glassy. Brass goods which contain a large proportion of zinc are much more susceptible to the action of water and other fluids, and more especially steam. The goods of this character become pitted because of the presence of zinc and are therefore rendered inefficient.

Brass Fittings Underground.

This is especially true of brass goods which are placed in the ground, for then they must resist not only the action of the water and fluids, but also the action of the earth as well.

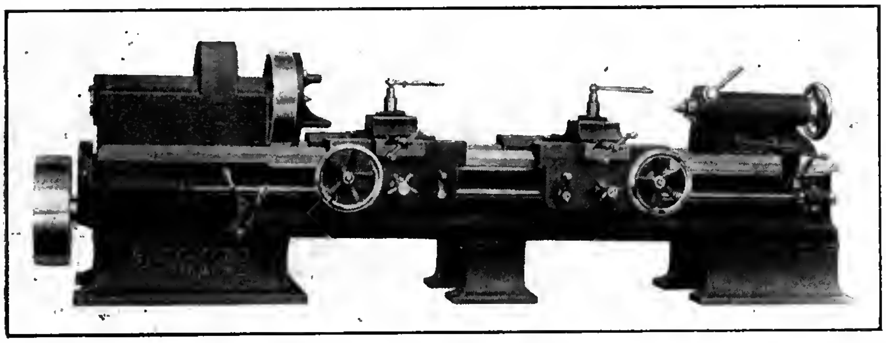
In its strength and qualities red brass is like a piece of good oak, white yellow brass is like a pine board and its wearing qualities are therefore not comparable with red brass.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

PLAIN TURNING MACHINE.

TO meet the demand for a simple and convenient machine adapted to plain turning requirements, the Bridgeford Machine Tool Works of Rochester, N.Y., have put on the market the lathe illustrated and described in this article. It has fewer parts than an engine lathe, is very powerful, and is simple and convenient of operation.



NEW PLAIN TURNING MACHINE.

There are three mechanical speed changes through heavy cut steel gearing and the use of a two-speed countershaft as furnished with the machine increases the speeds available to six. The feed box gives four changes of feed for each change of gear at the end of the lathe.

The gearing throughout is of steel, the gears for the speed and feed mechanism running in a bath of oil. The main driving gear is 6½ in. face, 3 pitch, with all other gearing in proportion. When motor driven, a 25 h.p. motor is employed. The drive is through constant speed pulley, the two levers at the front of the machine controlling all changes of speeds and feeds.

The lathe swings 27 in. over the ways, 13½ in. over the carriages, takes 8 ft. between centres with standard length of bed, and will work the best of high speed steels to the limit. It can be furnished with one or two carriages as desired.

PIPE THREADING AND CUTTING MACHINE.

THE ability to thread, ream and cut pipe in one continuous operation at twice the speed of existing machines is claimed by the Landis Machine Co., Waynesboro, Pa., for a new line of pipe threading and cutting machines which has been developed and recently placed on the market. These machines are designed to use the well-known "Landis" stationary type pipe die heads, which cover an exceptionally wide range with but one set of chasers. They are massive in construction and are equipped with the most improved mechanical and safety attachments.

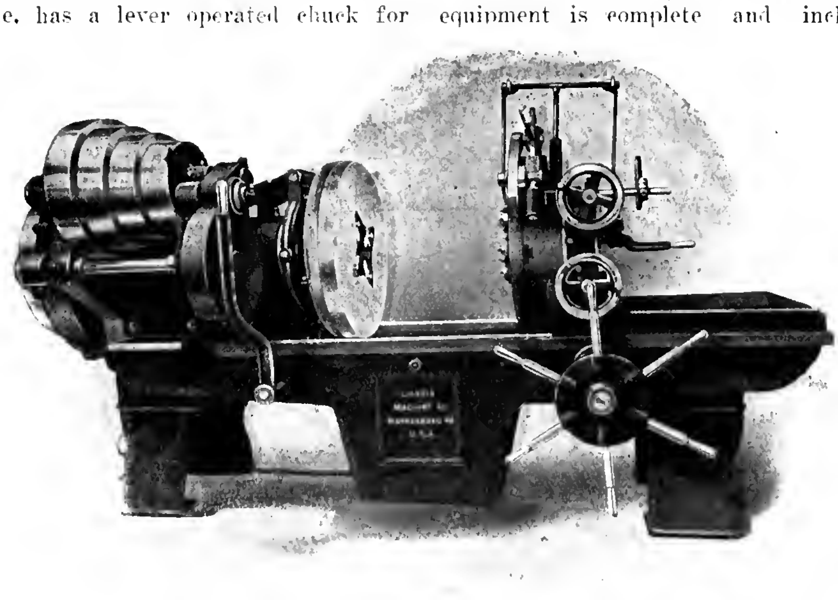
The line consists of three machines capable of threading from 1 inch to 8 inches, inclusive.

The most noteworthy feature of this type of machine is the ease with which it may be adjusted for the different sizes of pipe. This is due to the fact that the die head and gripping chuck have universal diametrical adjustments, and only one set of chasers is required to cover the range of each head.

The illustration shows the 4-inch machine, which, along with the 6-inch machine, has a lever operated chuck for gripping the work. Two stationary type die heads form part of the equipment of each machine, those of the 4-inch machine being one 2-inch (four chaser) head, and one 4-inch (six chaser) head. The Landis chasers are milled from flat bar steel and are hardened their entire length, and unless otherwise specified, are made of high-speed steel for Briggs' standard thread.

It is unnecessary to anneal, hob, or re-temper these chasers during their normal life, which is claimed to be frequently from ten to twenty times that of ordinary style chasers. In addition, the flexible rake and natural clearance between the serrated face of the tool and the surface of the work, eliminate all unnecessary friction at the cutting edge and render it possible to operate at a very high speed. The design of the 2-inch head allows the same chasers to be used for both right and left-hand threading, but the 4-inch head is limited to right-hand work. A point which calls for special attention is the fact that the cutting edge of the chasers can be located in the correct position at any time, irrespective of the amount of wear. The method adopted is simple, and insures the use of uniform and permanent cutting edges at all times.

Distinctive features of design include a universal centering chuck at the rear of the spindle; a one-piece frame with fluid-tight bottom; an accessible cone pulley on top of the machine; and all drive gears enclosed to comply with various factory inspection laws. The equipment is complete and includes counter-shaft, pump, reaming attachment, cutting-off tool, length gauge, pipe grips, nipple grips, wrenches, etc., to handle the work within its capacity.



"LANDIS" PIPE THREADING AND CUTTING MACHINE.

APPLICATIONS OF THE HEENAN COOLER.

THE Heenan cooler has met with much success as a medium for cooling air, which is circulated through the windings and about the armatures of large dynamos and motors. It is also employed for water-cooling purposes in internal combustion engines, etc.

This cooler is designed for the rapid and efficient transference of heat between two fluids, one of which (usually air) is in the gaseous, and the other in the liquid, state. The liquid to be cooled is contained in a tank in which a number of cooling cylinders revolve. These cylinders are built up by means of galvanized steel sheeting wound in the form of a spiral, the whole forming a large cooling surface in a very small space. The lower portion of the cylinders dip in the liquid to be cooled, and through the annular spaces of the upper half air is passed. The cylinders revolve at a slow rate, and are thus continually bringing fresh supplies of the liquid into intimate contact with the air. The cooling is effected partially by conduction of heat between the liquid and the air, and also, in most cases, by evaporation.

Where the liquid to be cooled is water, a small portion of the water, which is picked up by the galvanized steel plate, in the form of a film, is evaporated, and the latent heat required for this purpose is extracted from the metal contained in the cooling cylinders and hence from the liquid in the tank. It should be noted that the liquid is spread over galvanized steel sheets in the form of a thin film, and is not broken up into drops or globules. This means that there is little possibility of a portion of the liquid being carried away from the machine in the form of a loose mixture. The loss by evaporation is, therefore, the minimum possible by which the cooling effect can be produced.

For the purpose of passing air through the machine, a fan is used, which may be of the propeller or centrifugal type, according to the size and design of machine. A general idea of the construction of these coolers as fitted with centrifugal and propeller fans can be gathered from Figs. 1 and 2. The machines are usually driven by belt on to the fan spindle, the drums being revolved by suitable reduction gearing between the fan and the drum shafts. As the cylinders are mounted on ball bearings, they offer practically no resistance, and as the fans are of high efficiency design and construction, the power required to drive the coolers is a minimum. The standard design is somewhat modified when the coolers are to be used for special purposes and in special places. For example, special designs are employed when the installation is to be on board ship or for cooling compressed air.

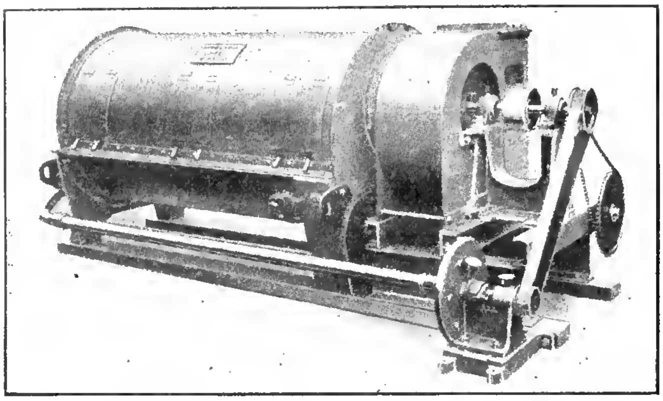


FIG. 1. STANDARD COOLER—CENTRIFUGAL FAN TYPE.

Cooling Water for Internal Combustion Engines.

One of the advantages of the machine when used for cooling water for an internal combustion engine is that it is positive in its action. By which is meant, there is a definite amount of cooling surface and a definite amount of air is passed through the machine per minute. Thus a constant cooling effect is produced. Experiments have shown that the machine is practically independent of climatic conditions, the action being such that all heat is dissipated as fast as it is generated if the machine is of size and capacity demanded by the engine it is cooling. This is a special advantage, and enables an engine to be run night and day for an indefinite period.

The space occupied by the cooler is small, while at the same time the apparatus is quite economical in the use of water. The cooler can be used to ventilate the engine-room, the air being drawn from the engine-room and discharged to the outside atmosphere. In tropical countries, especially, this is a decided advantage, because the air in the engine-room is generally oppressive.

In plants ranging up to 200 and 300 b.h.p. the cooler may be arranged so that the pump delivers the cooled water directly into the engine jackets, after leaving which, the water returns direct to the cast iron inlet funnel fitted on the water cooler. The water then flows

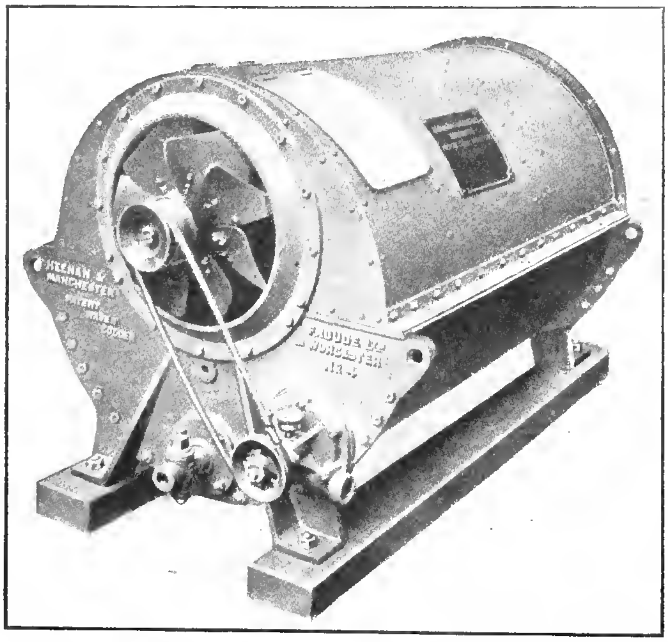

FIG. 2. STANDARD WATER COOLER—PROPELLER FAN TYPE.

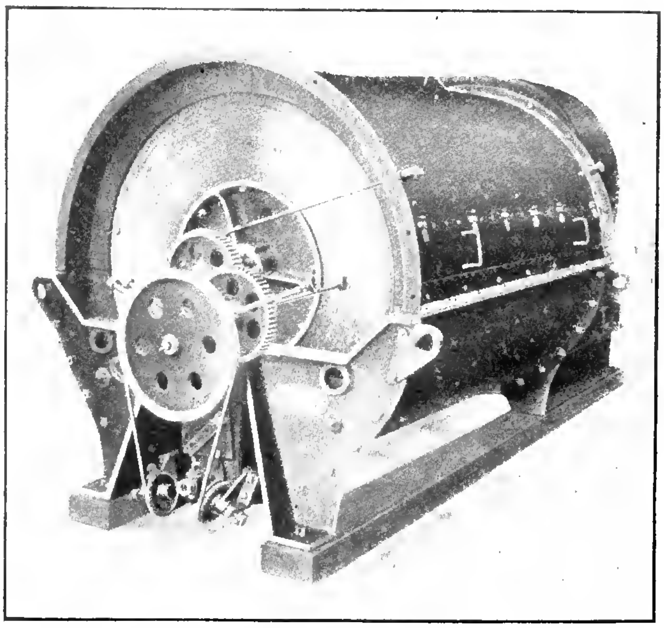

FIG. 5. VIEW OF OPEN END OF STANDARD COOLER.

through the cooler by gravity, and is passed by the circulating pump back to the engine water jackets. The loss of water by evaporation is made up by means of a float valve fixed in a small galvanized iron tank fitted at the side of the cooler, this float valve being connected up to the town's mains or some other source of supply.

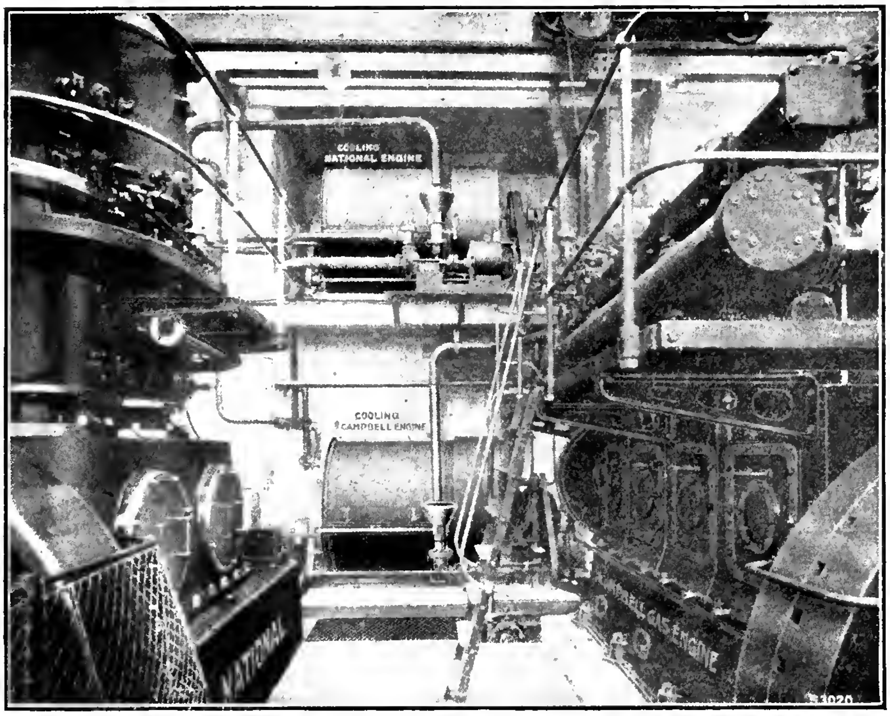

FIG. 3. TWO "HEENAN" COOLERS AT WORK ON TWO 350 HORSE-POWER VERTICAL GAS ENGINES.

With larger plants it is desirable to provide a small storage in the form of a tank or sump let into the ground. Some engineers have preferred a small overhead storage tank in order to provide a steady head on the engine jackets. Speaking generally, this tank or sump should have a capacity of a few hundred gallons of water, and its purpose is to counteract any unsteadiness of the circulating system at starting up, due to the comparatively small amount of water in circulation. When this system is employed, the float valve for making up the loss of water by evaporation should be fixed in the tank or sump. When the latter is provided, the pump should be arranged to deliver the water from the sump to the engine jackets and thence by gravity through the water cooler back again to the sump. If an overhead tank is provided, the water should flow direct to the engine jackets, and, through the water cooler, be returned to the tank.

Various methods are used to drive the cooler, it being often found convenient to drive the machine by means of a belt from countershafting. When electric current is available, however, a small electric motor is employed, the same motor being used to drive the pump. Fig. 3 shows an arrangement of direct coupled, motor-driven pumps, with the water coolers driven by means of belts from pulleys fitted on the shaft extensions of the motors.

It is usually advisable to provide a duct on the air outlet of the water cooler. This is always necessary when the cooler is installed in the engine-room, and even when the machine is working in the open air, it is sometimes advisable to provide such a duct, running, say, from ten to twenty feet vertically upwards. The duct should be of ample cross sectional area so as to offer no resistance to the passage of the air.

Cooling Water Used in Making Ice.

The importance of having cool water for use in plants which are manufacturing ice for commercial purposes hardly need be emphasized. When water is cooled by means of air, the atmospheric wet bulb thermometer limits the temperature to which it can be cooled. An efficient cooling plant is, therefore, necessary to reduce the temperature of water to anything approaching the wet bulb thermometer. With the Heenan cooler it has been shown that it is possible to reduce water to within half a degree or even less of the wet bulb thermometer, but a plant for such a duty would be large and commercially not very economical. Thus, for freezing plants it is the custom to provide machines which will cool the water to within a reasonable limit of the atmospheric wet bulb thermometer. The machine has shown up well under comparative tests in the warm months and in the tropics, and under these conditions shows its best efficiencies. To illustrate the importance of having cool water in a refrigeration plant the following figures will be interesting: One plant, receiving water at 60 degrees F., 70 degrees F., and 80 degrees F., consumed 78.8 h.p., 92.0 h.p., and 106.0 h.p. respectively.

Cooling Water for Air Compressors.

Where water is not very plentiful, it is often found useful to install one of these coolers to cool the water as it comes from the water jackets, and thus use the water over and over again.

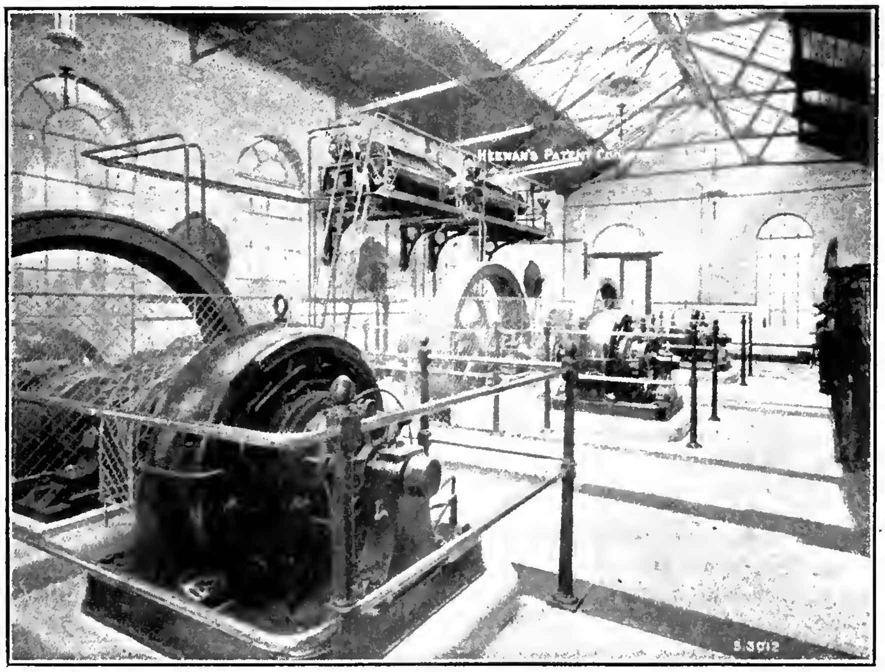

FIG. 4. TWO "HEENAN" COOLERS AT WORK IN A GAS, LIGHT AND COKE PLANT.

Various Applications.

The machines have been arranged to cool compressed air at various pressures; they have also been installed as intercoolers in compressors. The Beals system employs cooled compressed air extensively in refrigeration. The pressure is generally not much over 15 pounds. The air is used to agitate the water during the process of freezing, thus making a clear cake of ice. On board ship, the uses are also many and varied. Many trans-Atlantic liners have the coolers installed.

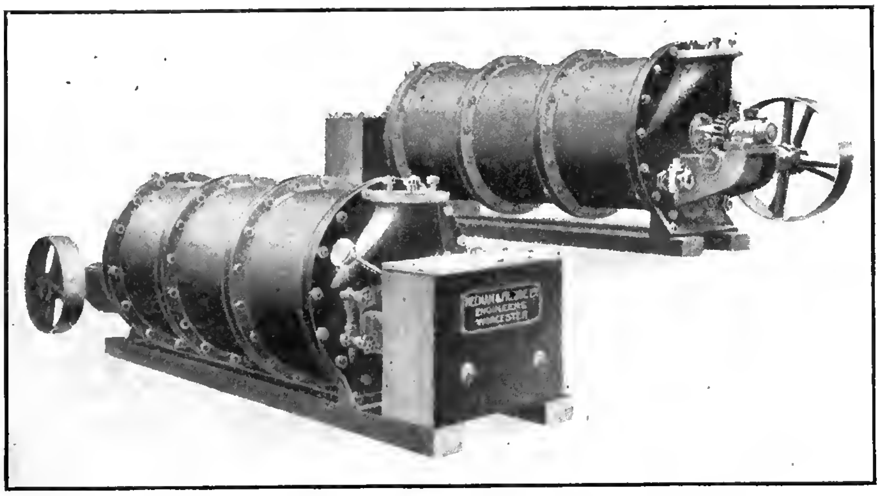

FIG. 6. TWO COMPRESSED AIR COOLERS IN ICE FACTORY.

By cooling the air, and removing thus the moisture in it, a dry blast for blast furnaces has been provided.

In chocolate factories and breweries an extensive application of these coolers has been made with excellent results. In tobacco factories the machine has been employed to produce air with a maximum of humidity, yet at the same time with no loose moisture.

In large steel mills producing forgings oil tempering is used extensively. The oil, of course, gets very warm in the course of time. Air has been introduced into it after passing through the cooler, and has been found to give excellent results.

The machine is manufactured by Messrs. Heenan & Froude, of Worcester, England, the Canadian representatives being Laurie & Lamb, Montreal.

HIGH SPEED DRILLING.

THE question of high speed drilling was discussed very fully by L. P. Alford, who read a paper on "Some Machine-Tool Developments of 1914," at a recent meeting of the Cleveland Engineering Society.

Last year, some sensitive drilling machines were put on the market, having spindle speeds as high as 10,000 r.p.m., although experimentally, drilling has been done with speeds up to 20,000 r.p.m. In the larger sizes of machines, 1 in. drills have been successfully run on tests at a speed of 12,000 r.p.m. and a feed of 1 in. per second in cast iron. (The author has seen these tests.)

In high speed drilling with numbered sizes of drills it has been found that the limit of the rate of speed is the muscular activity of the operator. Once the drill has entered, it can be pushed through as rapidly as the operator chooses to move his arm. The tendency of power feeds is toward still higher speeds for small drills than can be obtained by hand, and while the limit of speed has been frequently reached with sewing and shoemaking machines, due to lack of quickness in the operator, with machine tools the operator has always been able to keep up easily with the machine. It appears reasonable, therefore, to expect that the commonly used speeds for drilling and feeds of small drills will be greatly increased within the next few years.

The author discusses in detail the possible limitations in drilling practice. Of these, it appears that the wear of the drill is little affected, in the end, by the speed. The cutting edges of the drill are rather preserved than otherwise, at the higher speeds. As regards heating effects, it is claimed that the total heating effect at high speed is less destructive to drills than at slower speeds. The stresses on the drills are less, the drill is advancing rapidly into the cold metal and as the period of drilling an individual hole is short, the proportion of time that the drill is in the air to the time that it is cutting is increased. It appears, also, that at high speed drilling, less heat will be given to the tool by the chips than at low speed drilling. This is due to a hitherto unexplained fact, namely, that when the chips break off, they are cold and uncolored, but become hot and colored a few seconds later. This action has also been observed in milling and turning.

Harmony is a sort of an advance agent of success, and the best way for a foreman to maintain harmony is by being himself harmonious. It is not meant by this that he should be lax in exercising his authority—quite the contrary: but he can exercise it without that bulldog officiousness so repulsive to intelligent workmen.

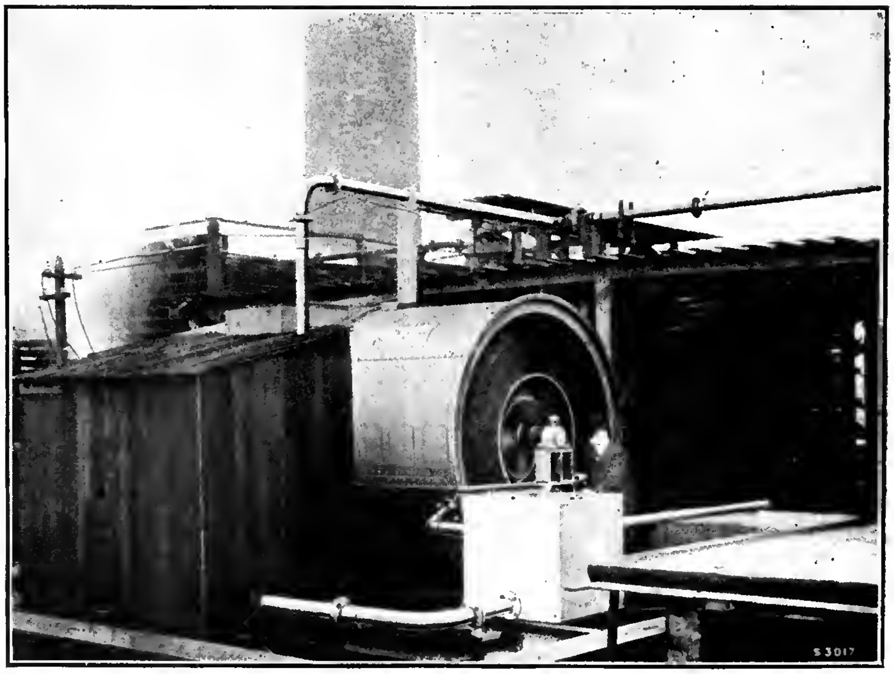

FIG. 7. "HEENAN" COOLER INSTALLED IN 200 TONS CAPACITY COLD STORAGE PLANT FOR COOLING THE CIRCULATING WATER.

THE WAR UNIQUE IN OPPORTUNITY.

THE facts that the chairmanship of the British Government Inventions Committee was offered to and has been accepted by no less a personage than Baron Fisher indicate at once the outstanding difference between the present war and those that have preceded it.

Since the days of Napoleon, none of the wars in which Great Britain has been involved have appealed so directly and irresistibly to her people. Many of us here in Canada, who a year ago did not know the difference between shrapnel and lyddite shells are not only now familiar with these missiles in their every detail, but are in addition sufficiently well posted as to converse fluently and confidently on matters military and naval generally.

Do we pause at all to consider these changed conditions? The conduct of wars in the past was almost entirely a Government affair. The training of men, the manufacture of munitions, the procuring of stores, arranging of transport and a myriad other activities connected with campaigning, were all carried out in more or less secrecy by Government Departments; the public meanwhile acquiring their knowledge of what was transpiring through the medium of the newspapers. Information so acquired was, of course somewhat scrappy, and as a result no very keen general interest was aroused.

In the present struggle tremendous issues are at stake, and of necessity our people must not only be conversant with these but so adjust themselves as to secure for our Empire an ultimate and abundant justification reward. To this end the united efforts of our manufacturers are bent towards the production of military commodities. Every little factory with power available feels called upon to assist, all of which plainly indicates that the successful prosecution of the present grim struggle is wholly dependent on the vigorous application of the knowledge acquired in the pursuit of peace time business.

To engineers more than to the members of any other profession this war has brought opportunity, and both in the workshop and office, and in the field we believe this many-sided craft is directing its energies to produce the most effectively helpful results. By those in the field, and they are numbered in thousands it is but reasonable to expect that numerous devices, ideas and contrivances have been evolved and put into practice, the dual recommendation of promptness and suitability ensuring the necessary appreciation.

Canadian engineers although working several thousand miles away from the storm centre of the war, need not feel that distance detracts from the value of their efforts. It may be of course that some may judge us by the number of shells shipped in a given time, or by some similar numerical production basis, yet it should not be forgotten by even our smallest employer or by our humblest employee that the sum of much indirect effort may even help as much if not surpass that obtainable from a brilliant technical invention of, it may be, restricted application. Various ideas have been adopted by shell makers in performing minor operations, which, had they been proposed with all seriousness in peace time, would possibly have received scant consideration by munition experts. One instance may suffice to show how the present exigency has operated to the mutual benefit of both War Office and shell makers.

In making shells in peace time it was required that the inside of the shell be machined all over so as to ensure a uniform thickness of wall, and perfect balance. This was not specified on shells made here, but on many occasions objection was raised to the amount of forging scale on the inside. This could only be removed with difficulty and with much loss of time if attempted with orthodox appliances. A boiler tube cleaner of the centrifugal type when revolved in a suitable fixture successfully overcame the trouble, but wouldn't it have been some shock if a shell maker had informed a munitions expert that a boiler tube cleaner was increasing the output by 30 per cent.

Instances such as these are of frequent occurrence, and the free exchange of ideas between shell makers in Canada and all over the Empire is only one of many indirect efforts, the combined effect of which will not only aid in bringing the war to a desirable termination, but will establish a common bond of manufacturing interest which is certain to have a powerful influence on the recovery and further development of British Commerce when ploughshares and pruning hooks again resume their normal occupations.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Toronto, Ont., August 3, 1915.—There is little change to note as regards the general trend of business. Industrial conditions continue to show some improvement, due largely to war orders, but also on account of the beneficial effect on trade generally resulting from these orders. This war business has materially helped to minimize the depression, while the expectation of a steady volume of business of this description is helping to maintain an optimistic spirit in business circles. The first year of the war—a year without a parallel—is closing with trade conditions far better than was anticipated, say, ten months ago. In the first month or so of this period, industrial conditions were in a chaotic state, but the banks and manufacturers took hold of the situation, with gratifying results. Large orders for war equipment were placed later on, and a gradual recovery followed, which became more pronounced as the effect of these orders was felt. This is particularly noticeable in the trade returns, which now show a large increase in exports; a distinctly favorable feature. It must, of course, be admitted that the war has adversely affected some lines of business, but against this, many others have been stimulated, the manufacture of munitions being perhaps the most striking example.

Steel Market.

Conditions in the iron and steel trade continue satisfactory, due almost entirely to war business, including, of course, shell steel. The mills are actively engaged in producing forgings and bars for shells, production having increased. Reports regarding the Dominion Steel Corporation are very satisfactory, this plant operating at over 90 per cent. of capacity. The Steel Company of Canada and the Nova Scotia Steel & Coal Co. are also working to capacity on war lines.

The situation in the galvanized sheet trade is still unsatisfactory, although prices of sheets have a weak tendency on account of the decline in the spelter market. Local quotations on galvanized sheets, however, are unchanged, and there is no immediate prospect of a reduction, as spelter at the present price is too high to be on a commercial basis.

Conditions in the steel trade in the States continue to improve, and quotations on bars are holding firm. There is a large export demand for bars for shells, and inquiries also represent a large tonnage. It is reported from Buffalo that Canadian interests have been in that market recently for 3,000 tons of billets, but are unable to place the order there.

There is no improvement in the high-speed tool steel situation, as supplies of tungsten are becoming more difficult to obtain. The British Government has placed an embargo on high-speed tool steel to foreign countries; this will not, of course, affect Canada except that the demand in the Old Country is so great that the mills will have difficulty in meeting the demand here. Prices have advanced about 75 per cent., with the probability of them going still higher. This applies to American brands as well as British. Carbon tool steel has advanced slightly, but is not affected by the conditions surrounding high-speed tool steel.

Pig Iron.

The market continues stagnant, with nothing of particular importance to note. Quotations are unchanged.

Scrap Metals.

The market is keeping steady and the general situation unchanged. Quotations are holding firm except for heavy and tea lead, which have declined, and are now being quoted at 4¾c and 3½c respectively. Scrap iron is dull, but unchanged.

Machine Tools.

Inquiries continue to flow in for shell equipment, although the amount of business booked has fallen off somewhat. Dealers, however, are not complaining, and anticipate a revival in due course. Far off deliveries are inducing prospective shell manufacturers to place their orders, and in this they are wise, for the extraordinary demand in Canada and the States for machine tools is taxing the makers to the limit. It is almost a question of first come, first served. The demand for second-hand equipment is as brisk as ever, suitable tools being quickly snapped up.

CANADIAN GOVERNMENT PURCHASING COMMISSION.

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George Gault, Winnipeg; Henry Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Supplies.

Business in machine shop supplies continues very satisfactory, and prices generally are holding firm. There is a good demand for lathe chucks, twist drills, high-speed tool steel, waste, cutting compound, belting, etc. The linseed oil market is weak and prices have declined 4c, oil being now quoted at 67c for raw and 70c for boiled.

ALLIES PURCHASING AGENTS.

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:—

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendance Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Attache, Russian Embassy, Washington, D.C.

Metals.

There are few price changes to note this week, and the market generally is dull. The tin market continues to decline, due to weakness, in London. The copper market is very dull, but quotations are unchanged. The spelter market is easier and lead unsettled, while antimony is very dull. The demand for metals for munitions is brisk, and ordinary business is gradually improving.

Tin.—The market continues to decline in London, due to lack of support. The New York market, however, is comparatively steady. Business continues dull, with little demand for spot tin. Tin has declined 2c, and is being quoted at 42c per pound.

Copper.—The market is very dull and prices are unchanged. It is reported from New York that the actual business placed both for home consumption and export during the month of July has probably been less than for any other month this year. Copper is quoted locally at 21c per pound.

Spelter.—Good business is reported for all deliveries, but buying is almost entirely on account of war orders, both directly and indirectly. The market has an easier tone, but qnotations are unchanged and nominal at 25c per pound.

Lead.—The market is weak, and it is probable that the "Trust" will reduce their quotation from 5.75c, New York. Local quotations are unchanged at 7¼c per pound.

Antimony.—The market is very firm, and makers are almost in a position to demand their own terms. There is no likelihood of any excessive supply of raw material becoming available. Quotations are nominal and unchanged at 40c per pound.

Aluminum.—The market is firm and the price unchanged. Local quotations are nominal at 40c per pound.

BIG INCREASE IN EXPORTS.

THE anniversary of Great Britain's declaration of war directs attention to Canada's accomplishments and some of the more outstanding results of the conflict as affecting this countrry.

The initial step, taken before the formal declaration of war was the offer by the Prime Minister of military assistance in the event of hostilities. Immediately after the war broke out, a complete Canadian division was accepted and hurried mobilization and equipment arranged for. It started on the 25th September, 1914, wintered at Salisbury, and in early spring went to France. The story of St. Julien, Ypres, Festubert, and Givenchy speaks of the character and the results.

70,000 Are Overseas.

Since then there has been more and steady recruiting, till about 140,000 men have been enlisted. Of this number upwards of seventy thousand are now overseas. Reinforcements are going ahead constantly. It is the intention to maintain in the field two complete divisions, and a third one may, quite possibly, be put there. In fact, there is no telling to what extent Canadian resources of men and munitions may be

drawn on. A Russian retirement in the east and the return westward of German hordes might easily produce conditions calling for much greater assistance from this country than has heretofore been thought necessary.

Exports Have Increased.

The war has interfered with trade, and has completely changed the balance of it, so much so that last month the figures of export exceeded imports by thirty-five millions. Import trade has dwindled materially, while exports, raw and manufactured, have much increased. While many lines of business have been adversely affected, the war has stimulated industry connected with munitions and equipment for the forces.

An estimate of war orders in Canada places the total at approximately three hundred and fifty million dollars. This includes orders by the Canadian and allied governments. Orders for shells alone are estimated at one hundred and fifty-two million dollars. About 160 factories are turning them out.

Revenue Goes Up.

The revenues which immediately started to decline after the war, were not very successfully arrested by the taxes imposed at the special session of Parliament in August. Those adopted by the last budget, however, have caused the revenue since then to equal and in most cases exceed what it was in the ante bellum months of last year. The war is being financed by British loans, while public works are being carried on by loans from Britain and the United States. The small jobs have been shut down, but the big undertakings are all going ahead. This policy has been followed from the start.

Canada has spent nearly a hundred millions on the war. It costs three hundred millions to run the country this year, and of this amount the war is costing half a million a day. The big item of outlay is the pay of officers and men. On equipment, about thirty millions has so far been spent. Speaking financially, while money is available for war purposes, municipal corporate or individual borrowings have been greatly restricted. There is no prospect of the flotation of a loan in Canada for the reason that all the money available is needed for commercial domestic purposes.

Recruiting.

Just at present efforts are being concentrated upon recruiting of the new regiments and their equipment. The work has gone ahead spendidly, but the figures of enlistment in the past month admit of improvement. This applies to all military divisions, but it is quite probable that harvesting activities have much to do with the situation, and that when they are finished, enlistment will rapidly be augmented.

MORE TONNAGE NEEDED.

THE Dominion Government is investigating the situation as regards the scarcity of Canadian tonnage, with a view to alleviating conditions in anticipation of the movement of the wheat crop. Representations are being made to the Imperial authorities and will be supplemented with information as to the increase in tonnage necessary to carry the crop without dislocating Canadian trade in general.

So far there has been no definite outcome of these negotiations. It has been represented from time to time that prize vessels captured from Germany and Austria should be placed in the mercantile service, but so far the Imperial Government have not consented. It is understood that this is one of the questions which Sir Robert Borden is taking up with the authorities in England, although there is no truth in the report that the Premier is arranging for the taking over of the Canadian crop.

THE ATLANTIC IN WAR TIME.

IN the harbor at St. John or Halifax, according to the Canadian Gazette, may be seen a number of the old square-rigged Canadian sailing vessels loading up for England. These relics of the nautical past are helping to fill the gap made by "orders of the Admiralty" in the ranks of the regular cargo boats. There is money in the business. British importers of Canadian timber, for instance, have now to pay £6 10s. per standard of 165 cubic feet for freight from St. John to Old Country ports.

One old "tub," to use the irreverent phraseology of the modern gold-laced officer in the merchant service, was sold not dong ago for $8,000. In one trip alone this same "tub" is said to have cleared $12,000 profit! An iron sailing vessel that cost $25,000 is said to have made $35,000 on its first trip across the Atlantic. Old "salts" who have been living on shore for many years have again donned their oilskins. A boot and shoe merchant, who had not sailed a ship for twenty years, sold his store, bought an interest in a brig, skippered it himself across the Atlantic, and cleared up $3,000 in a month. No more boot selling for him, he declares. The Atlantic is an interesting highway these war days!

Vibration is the chronic enemy of machinery, so seek to guard against it in every practical way.

CANADIAN SHIPBUILDING IN 1914.

ACCORDING to the list of vessels built and registered in Canada as issued by the Department of Marine and Fisheries, 1914 was a fairly active year in ship construction. In the '70's of last century, when the wooden sailing ship was still the glory of the seas and a main carrier of ocean-borne commerce, the measurement of vessels turned out of Canadian yards ran up towards 200,000 tons a year.

The steel tramp that on a low consumption of coal could push its way through the water at a speed of eight miles an hour or so was getting its start, however. It was better adapted to the needs of a growing commerce, and if on the ocean highway it could not keep up with the fine clippers and great three and four-masted sailers, it had other advantages which made it the fittest, and its old-type competitor could not survive. From 1874, when 190,756 tons was added to the registry, there was a gradual decline till 1896, when the additions to the list only measured 16,146 tons.

When the development of trade on the Great Lakes began to call for a larger class of steamers than had heretofore been employed, Ontario began to advance as a ship-owning and ship-building province, and has of late years been the chief contributor to the record. Last year the measurement of the new vessels was 43,346 tons, the largest figure in fourteen years; and of the whole, 23,167 tons was credited to Ontario.

The increase in the total of vessels registered was, however, only 35,457 tons, there being a reduction on account of the loss, sale or breaking up of older craft. According to the record the number and tonnage of vessels registered in Canada at the close of 1914 was as follows:

	Vessels.	Tons.
Ontario	2,100	314,660
Quebec	1,663	259,143
British Columbia	1,591	147,192
Nova Scotia	2,098	135,053
New Brunswick	1,052	55,522
P. E. Island	149	10,029
Manitoba	103	7,999
Yukon	11	2,295
Saskatchewan	5	529
Total	8,772	932,422

The average size of the registered vessels, it will be noted, is just over 100 tons. There are ships of large capacity on the list; but the majority are schooners or fishing barges, and even smaller craft, that some countries do not enter on their records of ships. They all serve a useful purpose, however, and play their part in the work of transportation of one kind or other.

Trade Gossip

The Collingwood Shipbuilding Co., Collingwood, Ont., have closed a contract with the Imperial Oil Co., for a steel tank steamer of the same type as the one now under construction for the same concern.

Toronto, Ont.—Delivery of the machine guns which Ontario is supplying to the Canadian forces at the front will begin October 30, when ten will be put in the hands of the militia department. More will be delivered weekly till December 18, when the last 130 of the 500 are due from the contractors.

Conditions Better in Steel Business.—Conditions are better than for the past three years, said J. H. Plummer, president of the Dominion Steel Corporation, who was in Montreal recently. He also said that many of the difficulties to which he referred at the annual meeting, had been overcome, though there was still some slight difficulty in securing tonnage to England.

Hydrographic and Biological Survey. The Marine Biological vessel, the Prince, has left to continue hydrographic work in the Bay of Fundy. The party consists of Dr. Cox and Messrs. Craigie, Chase and McMurrich, and will be gone about a fortnight. They will proceed to St. John, run a line of stations to Digby; thence up Annapolis Basin to Annapolis. Returning, they will run another line from Quaco to the Nova Scotia coast opposite: besides working a few midway the Bay on the return trip.

Make German Dyes Here.—Two Canadian companies are grasping the opportunity offered by the failure of German concerns to furnish dye stuffs to America. The last issue of the Quebec official gazette, announced the incorporation of the two new companies that will produce the dye stuffs. The Berman Dye Works, Ltd., of Montreal, is empowered to carry on the business of dyers and are also empowered to produce all necessary products for their industry. The Weedon Chemical Co., among its powers, has been given that of distilling wood and producing all sorts of chemical products.

Newfoundland Buys Guns.—The Newfoundland regiment has already two machine guns, the gift of Mr. William Duff Reid, president of the Reid Railway concern. Sir Edgar Bowring, president of the Bowring Bros. Steamship Co. has announced the gift of two machine guns from his company. The employes of Harmsworth Paper Mills at Grand Falls, in the interior of Newfoundland, will provide two more machine guns, and the employes of the Dominion and Nova Scotia Steel Co.'s mines at Wabana are each pledged for one thousand dollars, which will be devoted to machine guns also.

Machining Shrapnel Shells in a Steel Foundry Plant

Staff Article

Resourcefulness in gripping and mastering the details of shrapnel shell manufacture has not, as will have been noticed from our leading articles in this and recent issues, been confined to any particular section of Canadian mechanical engineering enterprise. The plant here featured, although not a leader in point of size, earns that distinction in its output.

THE conversion of a steel foundry, into a machine shop requires the exercise of considerable ingenuity, and in the case of the plant under review, it would be difficult to imagine that it had been anything else but a machine shop. At this plant both 15 and 18 pounder shrapnel shells are being produced, this article will, however, describe the manufacture of the latter only. There is, however, practically no difference between the two as regards their manufacture, except in less important details, such as cutters and inside tools, which are necessarily smaller for the 15 pounder shells. The same machines are used and the same sequence of operations for both calibres. A description covering the manufacture of 18 pounder shrapnel shells will, therefore, cover the 15 pounder also. The number of 15 pounder shells which have been manufactured is insignificant when compared with those of the larger calibre.

As the equipment was installed solely for the purpose of making shells, it was possible to make the layout to suit the sequence of operations. This feature in itself saves a lot of time and labor in handling the shells and also materially serves to increase production. Although some of the machines are not new, efficient tooling has produced very satisfactory results. This is particularly true as regards the air chucks which are fitted to some of the machines. They are quick-acting, and thus save a lot of time where otherwise much is lost.

Cutting off Shell Forging.

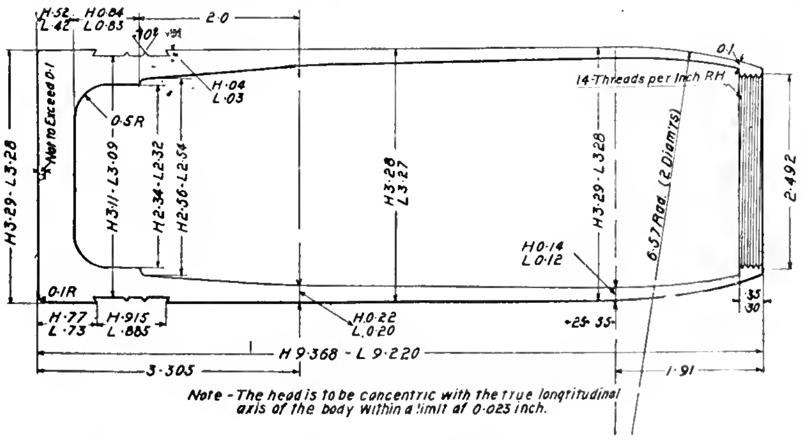
The first operation follows the practice adopted in the majority of plants and consists in cutting off a part of the open end of shell, which is of course ragged, sufficient metal having been left on for cleaning up. A cutting off machine supplied by the F. E. Garvin Co., New York, is used for this work. The shell case is secured in a chuck, the correct position being determined by a hook ended gauge, the straight end resting on the bottom of the shell inside, while the hooked end curves over the mouth of shell and marks the point where to start the cut. An ordinary parting tool mounted in a tool holder on a cross slide at the side cuts off the shell end.

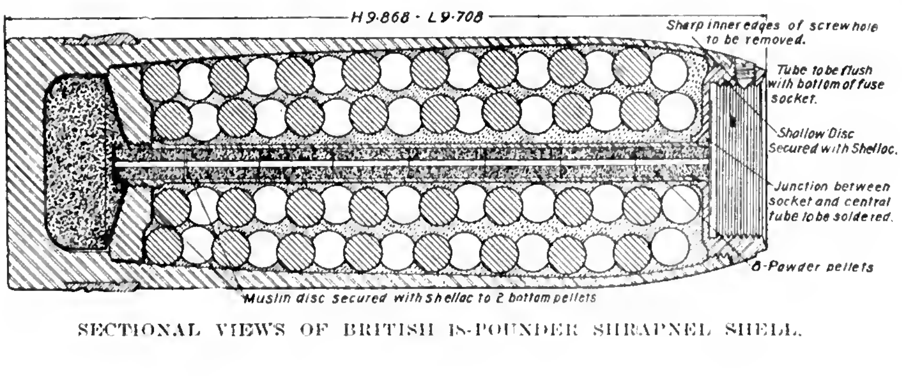
Centering.

The shell casing is not perfectly concentric and this defect has to be guarded against in subsequent operations. To reduce the possibility of error from this cause the base of shell is centered, the center being retained until all machining operations on the shell body have been completed; thus the shell revolves about the same centre during all the operations. The centering is done on a "Bertram" turret lathe equipped with an expanding mandril, while on the turret is mounted a small countersink drill for forming the centre in the base. By this method the centre of the base is true to the inside of the shell, which it will be remembered is not yet machined; therefore the outside when turned up will be concentric with the inside of shell.

Rough Turning Outside Shell.

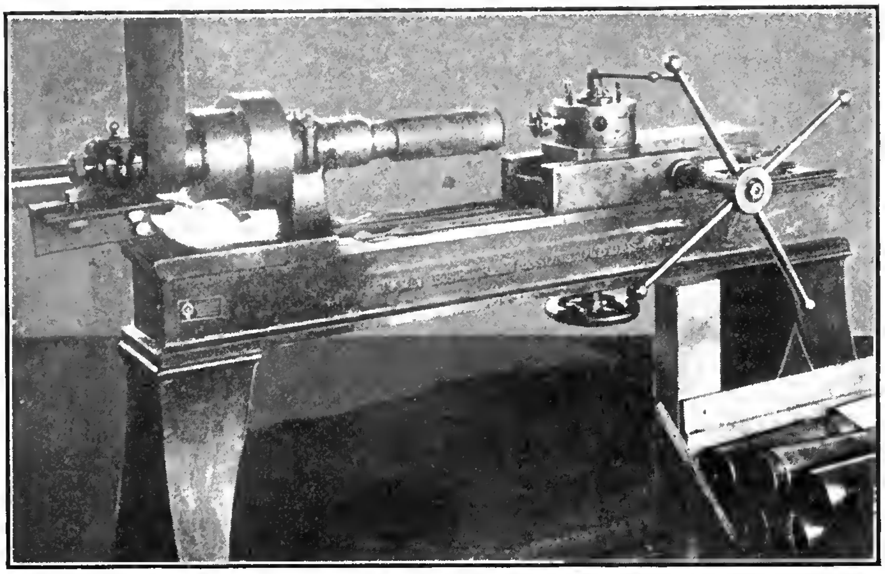
The shell case is next rough-turned





SECTIONAL VIEWS OF BRITISH 18-POUNDER SHRAPNEL SHELL.

on an engine lathe built by the R. McDougall Co., Galt, Ont. The lathe is equipped with a short taper mandril instead of the usual chuck. The mandril has 3-taper steel bearing surfaces over which the shell is forced a sufficiently tight fit, while the hollow centre at the base end engages with the tailstock centre. This arrangement permits of the entire length of shell body being machined. The bevel on outside of nose is taken care of by a cam device attached to the bed of lathe at the back. The cross slide has an extension with a roller at the end engaging with the cam, thus giving the required bevel and preparing the nose for the closing in operation at a later stage.



COUNTERSINKING CENTRE IN SHELL BASE.

Rough and Finishing Boring Inside.

At the next operation the shell casing is rough bored and finished inside, also faced to length. A. Walcott & Wood combination engine and turret lathe is used for this work, the lathe being fitted with an air chuck designed by the Electric Steel & Metals Co. of Welland, Ont. The air chuck is of the same type as fitted to the lathe for machining and threading the nose, and will be dealt with later, when that operation is being described. The turret holds four tools, the first being a boring bar with a cutter, and the second, a large drill. Both these tools are used for the same purpose, viz., to remove any scale that may be in the forging. The third turret face holds a bar with a cutter for rough boring the inside of the forging, the end of the cutter being shaped to conform to the profile of the inside of base. In the bar is an inserted cutter for facing the forging to length. The fourth tool is similar to the preceding one and is used for finishing the inside and base profile. The bar has at its base a collar stop gauge for regulating the depth of cut at the base inside.

Rough Facing Base.

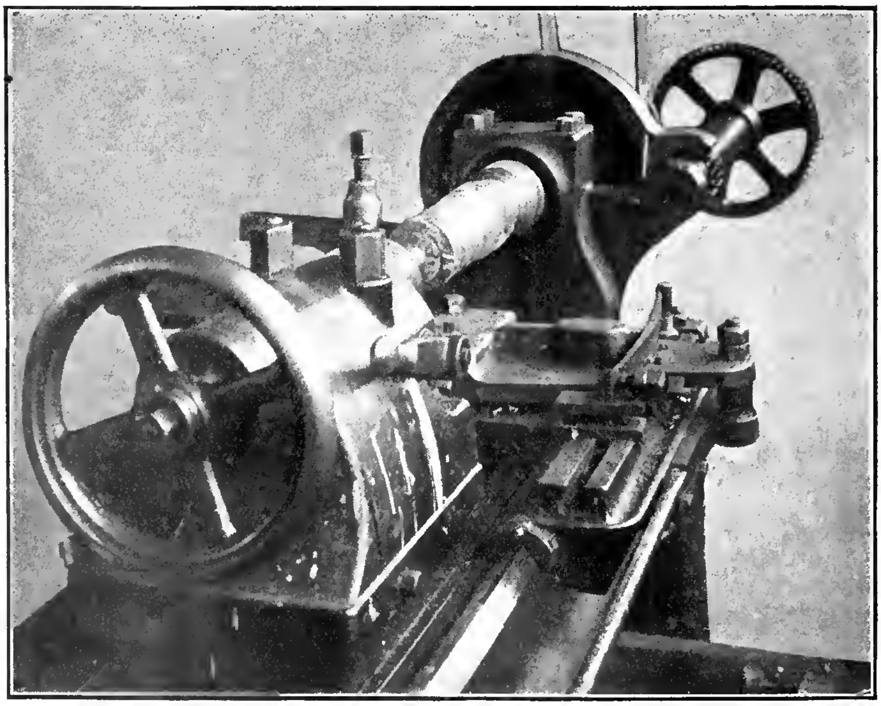
The next operation consists of rough turning the base of shell which up to this point has not been machined. In some plants this is usually the second operation. A cutting off machine built by John H. Hall & Sons, Brantford, Ont., is installed, and is equipped with back and front tool holders mounted on separate cross slides, but operated by the same spindle which is threaded right and left hand, so that both tools feed in towards the centre at the same time. The back tool is set ahead of the front, the cut thus being equally divided. Sufficient metal is left to form the centre already referred to. The shell is secured in a universal chuck while inside the hollow mandril is a fixed stop for locating it, the end of stop resting against the inside of base of shell.

Finish Facing Base.

At the next step, the base is finished except that the centre is left on. This work is performed on a turret lathe supplied by the A. R. Williams Machinery Co., Toronto. The shell is held in a two-jaw chuck and is set in the correct position by means of a bar in manner similar to the preceding operation. On the turret is mounted a fixture with three rollers for holding the base of shell, a broad cutter for facing up the base, and a smaller cutter at the side for rounding off the corners. A stop device under the turret regulates the feed.

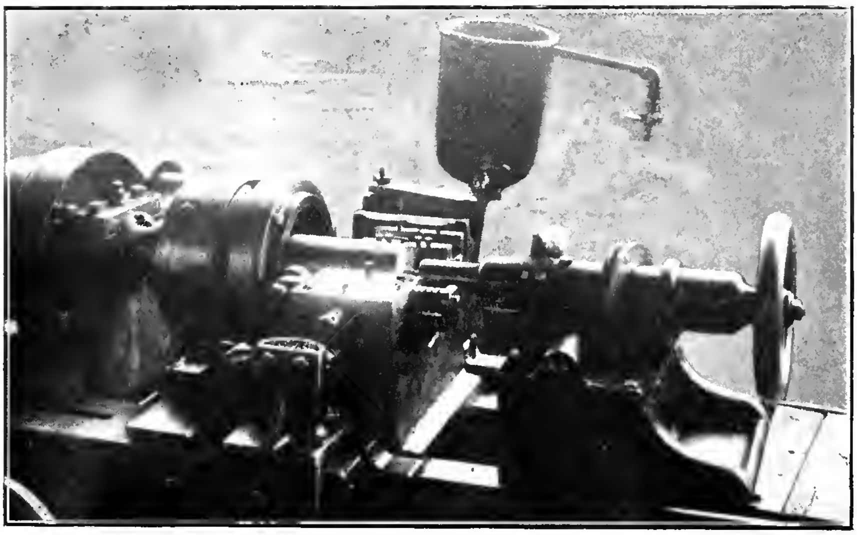
Machining Driving Band Recess.

The copper driving band recess is now machined on an engine equipped with a "Bertram" waving and dovetailing attachment. The lathes were supplied by the Stevens Co., of Galt, Ont., and the A. R. Williams Machinery Co., Toronto. The nose end of shell is held in a universal chuck to which is attached a three-point cam for forming the wave. The centre on base of shell, which by the way has not as yet been cut off, engages with the tailstock centre. The front and back tool holders are mounted on separate cross slides, both being on a fixture fastened to the lathe bed. The front or waving tool



ROUGH TURNING OUTSIDE OF SHELL BODY.

holder has in addition a slide to permit the necessary lateral motion. Fastened to the saddle are two brackets at the back and one at the front, each bracket having a cam on the inside for feeding the tools during the operation.



GROOVING AND WAVING COPPER BAND RECESS.

The front tool holder contains a bar having at one end a roller and also the waving and grooving cutters. A strong spring on the outside holds the roller against the face of the cam. The dovetailing fixture at the back has two hook-nosed tools, left and right hand, secured in holders working in diagonal slides to form the undercut or dovetail. In operation, the tools being in position with the roller against the cam, the saddle travels in a direction away from the chuck, bringing the cams up to and at the back of the tool holders and forcing them in gradually, thus machining the groove to the required form and size. As regards the front tool holder, the cam presses on the lower part of the fixture, thereby leaving the tool holder free to oscillate while forming the wave lines and cutting the groove which is done by the same tool. This is the last machining operation previous to the heat treatment.

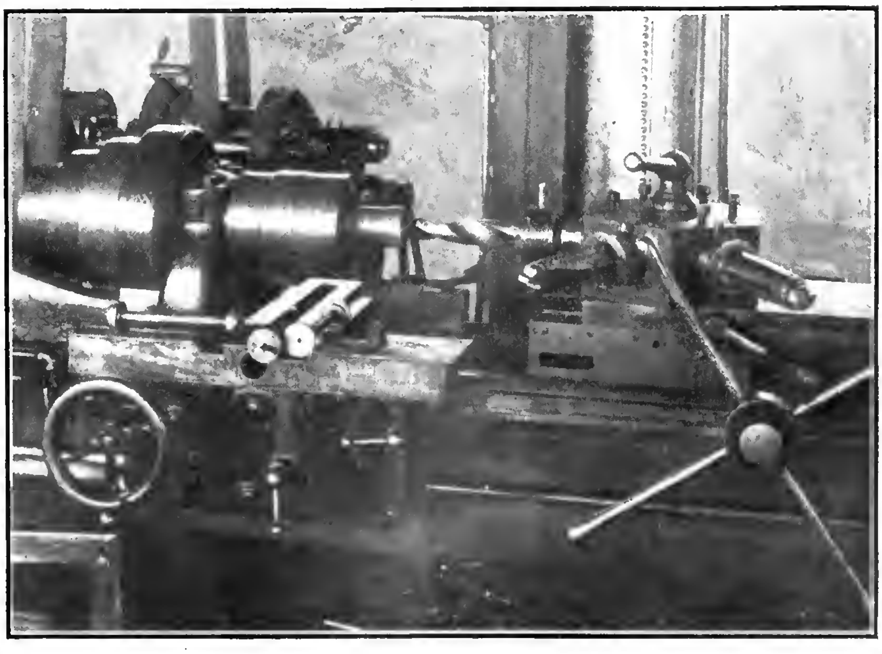
Heat Treating.

The important operation of heat treating now follows, in which the shell is brought to the required tensile strength. In this particular plant there are three distinct heatings. In the first place the shells are pre-heated in a gas furnace, constructed of brick and shown in the foreground in the illustration. The object of the pre-heating is to obviate the molten lead being cooled too much during the hardening process which follows. In the pre-heating furnace the shells are brought to a dull red and are then immersed for one minute in molten lead, the furnace temperature of which is at 1,575 degrees Fah. The shells are next dipped in an oil bath, taken out and cooled. At this stage the degree of hardness indicated by a test on a "Shore" scleroscope is around 55.

The drawing or tempering process now follows. The shells are put into another furnace also containing molten lead as a heating medium for 5 seconds, the temperature being 1,050 degrees Fahr. They are then taken out and allowed to cool gradually. The degree of hardness after tempering ranges between 41 and 45.

The furnaces are heated by natural gas, one being shown to the right of the pre-heating furnace, the others being behind. The oil quenching tanks are also on the right hand of the furnaces. The oil tanks have a water jacket to cool the oil and are equipped with a device for forcing air, from an adjacent compressor through the oil to keep it in motion and so to assist in the cooling process. Two electric pyrometers supplied by the Canadian Hoskins Co., Walkerville, Ont., are installed in this department for indicating the temperature of the various furnaces.

When cool the shells are arranged in lots of 120 in racks or boxes according to their series, a few of each lot being selected at random to undergo the test for hardness on a "Shore" scleroscope. Each shell has up to this point had a heat number stamped on, but after being tested they are identified by means of the series number; a record, however, is kept of the heat number. Before being tested, each shell is cleaned at the "set-up" point by means of a wire brush, in order to remove scale and have a clean surface for testing. A full description of the Shore scleroscope is unnecessary at this juncture, it being sufficient to say that a number of readings are taken, the shell being moved around on the carrying block between each test. A record is made of the average reading and one shell is selected from the series in order to provide a test piece which is cut at the set-up point. This is formed to suitable shape and is sent off to be tested by a government inspector who ascertains its tensile strength. The connection between the scleroscope readings and the tensile strength is that they bear a definite relation to each other, the degree of hardness being proportional to the tensile strength of the metal.



ROUGHING AND FINISHING INSIDE OF SHELL BODY AND FORMING OUTSIDE NOSE BEVEL.

Closing in the Nose.

The hydraulic press will be noticed on the right hand of the illustration.

This was built by Wm. R. Perrin & Co., Toronto, who also supplied the triplex pump and accumulator for operating it. The nose of the shell is first heated to a nice cherry red in a gas heated furnace containing lead, the latter being similar in construction to those already described. The diaphragm is dropped in and the shell is placed base down on a fixture attached to the table above the ram, the fixture having two vertical guides for keeping the shell central. When the pressure is applied, the ram rises and forces the nose of shell into the cone-shaped die in the casting above, thus closing it in to the correct size and profile. The press exerts a pressure of 1,000 pounds for this operation. The die is cooled from the water tank shown on top of the press. The shells are allowed to cool slowly and are then removed for the next machining operation.

Machining and Threading Nose.

This operation consists of facing the shell to length, reaming out preparatory to threading, finishing nose profile outside and inside, and threading the nose. A number of engine lathes built by the London Machine Tool Co., of Hamilton, Ont., are employed for this operation, each lathe having a turret mounted on the saddle and being tooled up to suit the work. An interesting feature to be noted is the air chuck which was specially designed for this class of work. The chuck proper consists of a circular casting or hood bolted to the driving plate and contains three jaws inside for holding the shell. At the back of the jaw is a plunger operated by a spindle inside the headstock and connected to the air cylinder at the extreme left hand of the latter. The shell being placed in the chuck, and the air admitted to the cylinder, the plunger forces the jaws forward, grasping the shell securely.

The first turret face holds a reamer with a stop bar projecting in the centre to give the correct length to the shell when the small cutter at the side of the reamer is in operation. The reamer prepares the nose for threading. At the second turret face is a bar with a broad curved cutter for making the finishing cut to the nose profile outside. The third turret face holds a bar with a similar cutter, but curved to suit the inside profile of nose. This cutter cleans up the inside of nose profile at the back of the part to be threaded. A "Murchey" collapsible die is mounted on the fourth turret face for threading the nose. This operation completes machining on the inside of shell. The gauges used in this operation are shown on the lathe saddle in the illustration.

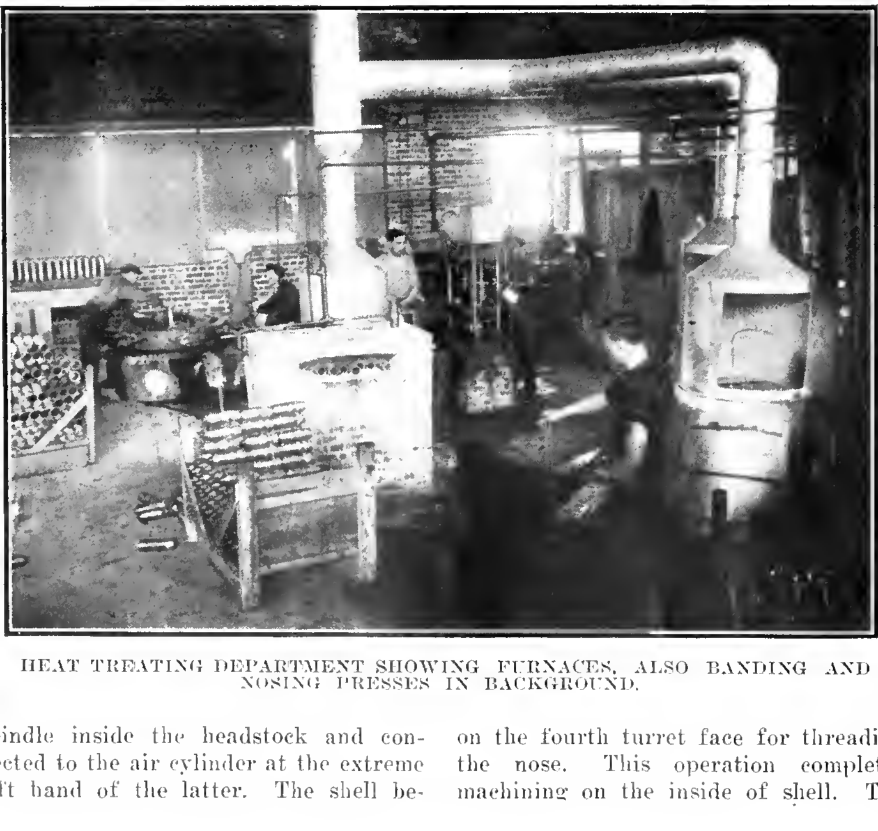
BANDING AND NOSING PRESSES AND ACCUMULATOR.

Finishing Outside Body.

Alternative methods are used for this operation, the shells either being turned on an engine lathe or finished on a grinder. For the first mentioned method an engine lathe built by the F. E. Reed Co., Worcester, Mass., is used. There is no cam attachment used in this case as it will be remembered that the nose profile has already been finished, thus the straight part of the shell body only requires machining or grinding as the case may be.

For the machining operation a plug centre is screwed into the nose of the shell and placed on the live or headstock centre of lathe, the base centre engaging with the tailstock centre. One light cut is only necessary to finish machining the body of shell, and this is done by an ordinary turning tool.

For the grinding operation a 10 x 24 in. plain grinder built by the Landis Machine Co., Waynesboro, Pa., is used. As in the preceding case the straight part of the shell only is finished and a "Hart" emery wheel is used for the purpose. The grinder is belt driven from a motor located on the floor at the back of the machine, a satisfactory arrangement considering the nature of the work. For grinding the shell, the same type of centre is used for the nose end as for the machining operation. The base end of shell is carried in a cup centre. About 1-32 in. only is removed when grinding.



HEAT TREATING DEPARTMENT SHOWING FURNACES, ALSO BANDING AND NOSING PRESSES IN BACKGROUND.

Pressing on Driving Band.

It will be noticed in the illustration that there are two banding presses. The press in the foreground was built by the Goldie-McCulloch Co., Galt, Ont., and is for the 18 pounder shells. The press immediately behind is for the 15 pounder shrapnel shells and was built by the Canadian Fairbanks-Morse Co.,

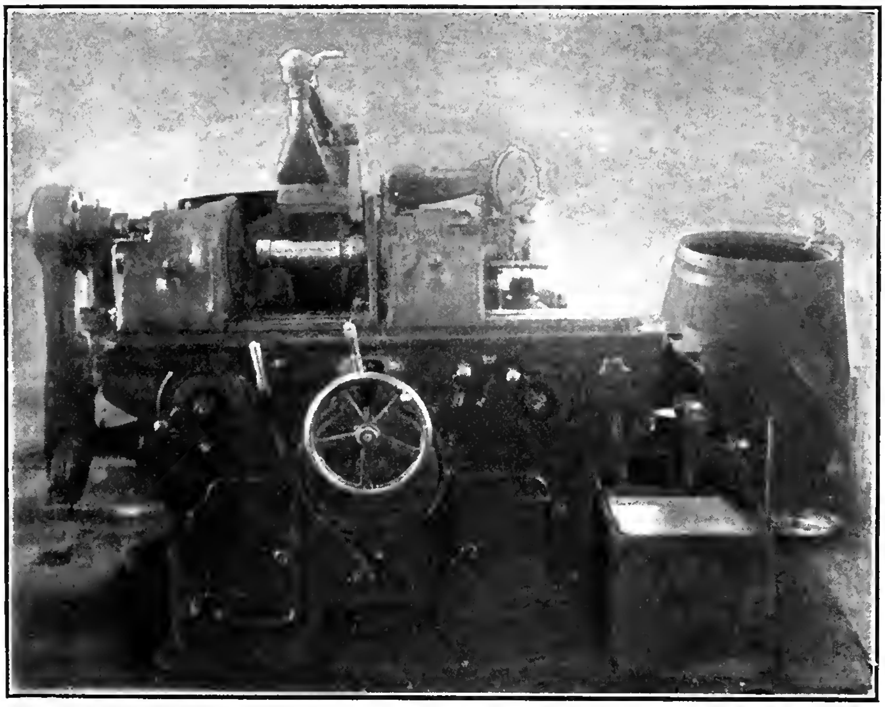
Toronto. They are both very similar in construction, each having six hydraulic cylinders with rams converging towards the centre at the end of which are steel dies conforming to the shape of the rough copper band. Both presses are operated from one pump and accumulator built by Wm. R. Perrin & Co., Toronto. The pump is located behind the accumulator and the press will be seen to the right in the illustration.

The method of operation is the same for both presses. The copper band is slipped over the base into the recess, the shell being then placed on a plate in the centre of the press. The operator moves a lever and the rams squeeze the copper band into the recess. The pressure is now taken off and the shell given a slight turn, after which the operation is repeated, thus equalizing the pressure on the band. The copper band now completely fills the recess and the shells are removed to have the bands turned.

Turning Copper Bands.

The copper bands are turned on a machine built by the Jenckes Machine Co., Sherbrooke, Que. This is equipped with a universal chuck mounted on the headstock spindle which is driven by friction clutch pulley controlled by a lever within reach of the operator. On the bed of the machine is clamped a saddle which carries the front and back tool slides.

The shell is placed in the chuck and is located in the correct position, by a swinging finger pivoted on the front tool block, before the chuck is tightened. The front or roughing tool is held in a holder working on a cross slide on the fixed saddle. The tool is fed in by a hand wheel to a dead stop. The front tool holder is provided with a hinged scraper rest for removing the ragged edge at each side of band after tooling. The rear or finishing tool is held in a steel block working in a slide on a fixture on the saddle at the back. The tool is mounted above the work, but can be adjusted to pass down behind the work, and in passing shave the band to size. The feed on the back tool is controlled by a lever and pinion.



"LANDIS" GRINDER FINISHING SHELL BODY.

FINISHING AND THREADING NOSE INSIDE. FORMING NOSE PROFILE OUTSIDE.

Removing Centre and Marking.

The centre projecting from the base has up to this stage been retained and used in the various machining operations, this method being adopted, as already stated, in order to obtain a shell as concentric as possible, for by always working from the same centre, this can more easily be accomplished. As there are now no more machining operations on the shell proper, the centre is cut off. This operation is done on a lathe supplied by the London Machine Co., Hamilton, Ont. The shell is now ready for marking, and for this operation is taken to a bench where the various markings are stamped on by hand.

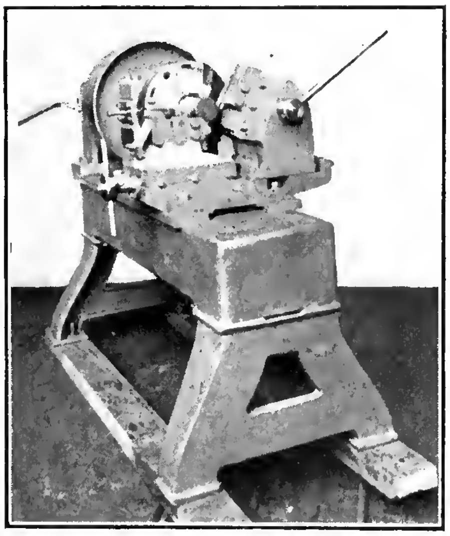
Filling and Assembling Shells.

The shells go next to the assembling department where the various parts are put together and the bullets and resin poured in. The tin powder cup is first slipped past the diaphragm into the powder pocket, and the brass fuse tube screwed into the diaphragm. For pouring in the bullets, a wooden structure has been devised, this consisting of a bin containing the bullets situated above the operator and supported on a frame. The bullets fall down a spout into a receptacle which tilts when it contains the approximate total number, the latter pouring into the shell which has been placed underneath. To help the bullets to consolidate in the shell an air jarring apparatus is used which vibrates the shell while the bullets are being poured in. The shells are now taken over to a resin kettle where hot resin is poured in to form a matrix for the bullets. Immediately afterwards the shell is weighed

and the weight adjusted within the prescribed limits. In order to obtain the correct weight, it may be necessary to add a few buckshot or take out a little resin. The brass socket is next screwed into the nose, and the fuse tube soldered in the hole in the socket.

Finishing Sockets.

When the brass sockets are received at the plant they are already machined and threaded except for that part outside which forms the fuse plug seat. A "Bertram" engine lathe with turret attachment is employed for machining this. The shell is chucked, and the outside of the socket rough turned, the bar with cutter held in the second turret forming the fuse plug seat on the outside of the socket. The third tool faces up the bottom of the socket at the same time, removing that part of the fuse tube which projects after soldering. The brass socket is now hand tapped, and the shells cleaned and weighed so as to be ready for the final Government inspection. During this they are carefully weighed and gauged, and one selected out of each series for the firing test. Before being taken to the painting department, a brass plug is screwed into the nose. These plugs, as in the case of the sockets, are made outside, and do not require any further machining.

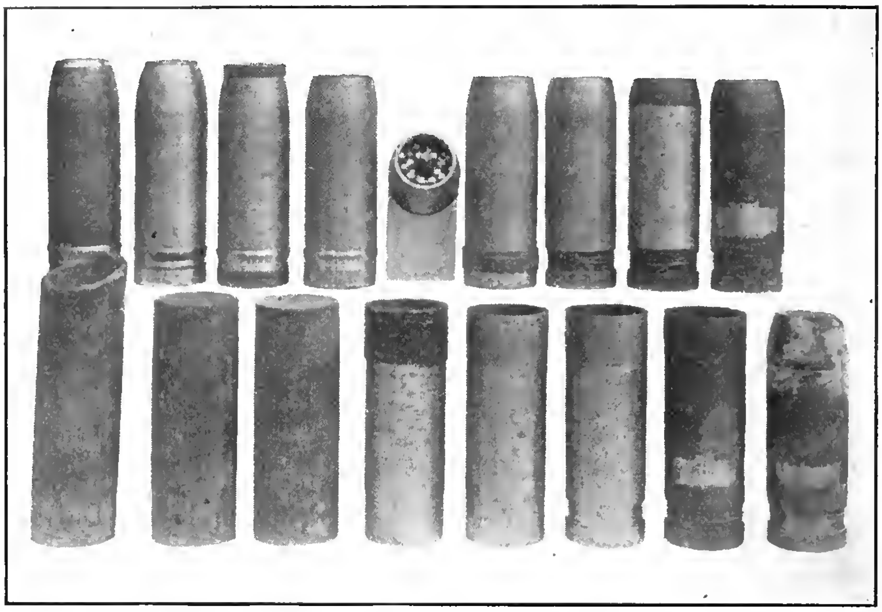


JENCKES MACHINE CO. BAND TURNING LATHE.

Painting.

The accompanying illustration shows the painting and shipping room. The painting machine is a portable outfit, and consists generally of a motor which drives three cup-shaped shell holders located on the top of the table. The motor is situated below, as shown. The priming coat is of course grey, the finishing coat black, and the nose red; the paint is applied by hand. It will be noticed in the illustration that the shells on the floor are arranged in their series, the packing cases being seen at the left.

No particular reference has been made to the gauging feature which plays a most important part in the manufacture of any type of shell. The gauges used are standard, and are as used in most plants making shells. At each operation the shells are carefully checked with high and low gauges, and, in addition, inspectors specially appointed examine each shell at certain stages of manufacture.



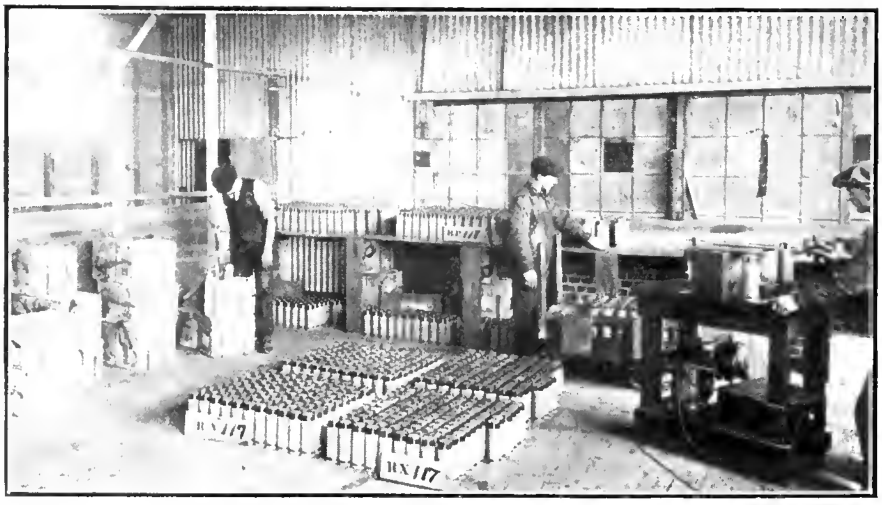
SHRAPNEL SHELLS IN VARIOUS STAGES OF MANUFACTURE AFTER WHICH THEY ARE READY TO BE MADE IN "FIXED AMMUNITION."

ELECTRIC FURNACES.

THE principal advantages to be derived from the use of electric furnaces in preference to combustion furnaces for reheating in steel works are summarized by T. F. Bailey as follows:—"More accurate temperature control; non-oxidizing atmosphere; saving in space; elimination of blast and stack; uniformity of temperature throughout the heating space; simplicity of control; smaller amount of heat lost to the surrounding atmosphere; and cleanliness of surroundings. The smaller amount of heat lost to the surrounding atmosphere makes the work around an electric furnace far more healthy and agreeable than with the combustion furnace."

For furnace temperatures not exceeding 2,500 deg. Fahr., the electric furnace will answer any reasonable requirements, and so far as the actual fuel cost alone is concerned, at the rate of one cent per Kilowatt-hour, will compare favorably with oil furnaces burning oil at four cents per gallon.

The modern idea seems to be that as such a large part of our life is spent in the occupation of business, it ought to be one of pleasant relations and enjoyable conditions. These are possible only as justice, good feeling and honesty prevail.



PAINTING DEPARTMENT AND SHIPPING ROOM.

The Design and Constructional Features of Plug Gauges--II.

By C. Hattenberger

The application and maintenance of proper plug gauges for certain lines of manufacture mean greater efficiency and interchangeability. Where a large number of similar pieces are required, suitable gauges are most essential, and should be provided.

ADJUSTABLE PLUG GAUGE.

FLAT gauges are frequently employed because of their light weight. In some cases they are the only gauges that can be used at all, because cylindrical gauges of the same size would be too cumbersome. Fig. 23 shows an adjustable gauge. The frame (A) is an aluminum casting, having holes drilled to receive the screws for holding the hardened measuring blocks (B). When the gauge shows wear, it is only necessary to disassemble and reduce the thickness of the shims (C), after which it can again be assembled and ground to size on centres provided for the purpose in the frame.

Fig. 24 shows an inexpensive form of flat plug gauge limit type of go and not go ends and exact size in the centre.

A plug gauge that can be used without drawing the boring bar from the hole is shown in Fig. 25. The illustration, the writer believes, is self-explanatory.

Ball Race Gauges.

Fig. 26 shows a gauge used for gauging ball races. It consists of the following: A sliding plug (A), having the proper limits; these, for obvious reasons, are shown exaggerated in the illustration. The spider (B) is milled and drilled to receive the oscillating fingers (C). These are held against the plug by means of helical springs shown. The measuring points (D) are lapped to the proper length and radius, and should be a tight fit in part A. A small stud (E) governs the movement of the sliding plug.

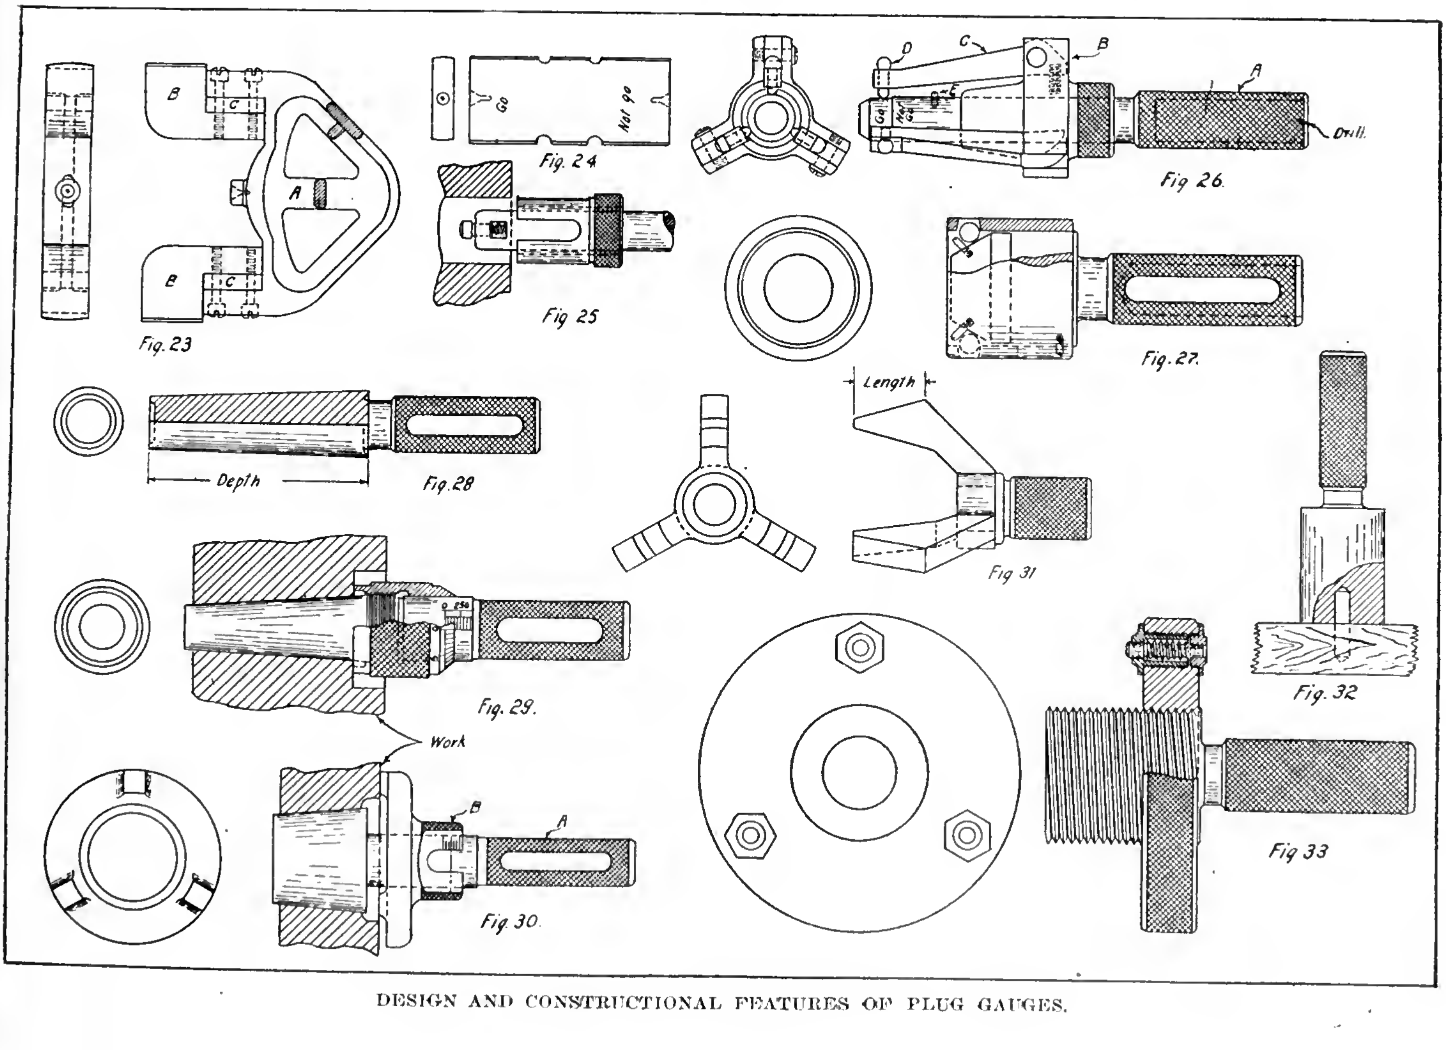
Another form of ball race gauge is shown in Fig. 27. This also works on the principle of a sliding plug. The measuring points in this case are two steel balls. A tubular cage (B) and two studs keep the balls from dropping out of place.

The gauge in Fig. 28 is the type commonly used for gauging taper holes; the large end shows the depth to which the gauge should enter.

Accurate Taper Gauge.

Where a very high degree of accuracy is required, a gauge similar in construction to that illustrated in Fig. 29 will answer the purpose. It operates on the micrometer principle. The graduations read to a thousandth part of an inch.

Fig. 30 is also an indicating gauge, but not so well adapted for accurate work. To the plug A is fitted a movable ring (B). A flat is milled on B. On this are marked the graduations. A zero line is inscribed on the circumference of the straight portion of the plug. Attention is called to the three bosses on the ring (B). These must be ground at right angles to the axis of the hole.



DESIGN AND CONSTRUCTIONAL FEATURES OF PLUG GAUGES.

The type of gauge shown in Fig. 31 is for measuring the relation of a taper to a shoulder or bottom of a blind hole. When the ends and circumferences of the three fingers are all in contact with the work, there will be no perceptible shake of the gauge in the hole.

Protecting Plug Gauges.

Referring to the illustration, Fig. 32, it will be seen that a hole is drilled in the end of a plug gauge. This is done to allow the gauge to be placed over a pin inserted in a shelf used for holding the plug gauges. It can readily be seen that gauges so arranged are kept from shifting about, and are protected from injury.

Thread Testing Gauge.

In Fig. 33 is shown a flush pin gauge used in connection with a thread plug gauge. It is used to determine if a machined face is at right angles to the axis of a threaded hole. The plug is screwed into the hole for about two-thirds of its length. The ring containing three flush pin gauges is then brought forward against the machined face and the relative position of the flush pins noted.

Keyway Gauge.

Because of the large amount of work done on the broaching machine, gauges of various shapes are needed to check results. Some, if made in the usual manner—that is, made solid, would be too costly. A built-up gauge shown in Fig. 34 is used for gauging three keyways spaced 120 degrees apart.

Duplex Gauge.

Fig. 35 illustrates a type of checking gauge for gauging the diameter of two holes. It also serves to gauge their centre distance or relation to each other.

Multiple Gauge.

Fig. 36 shows how two bores and three faces are measured by means of a single gauge. The flanged bushing (A) is hardened and is ground on the diameter and the inner face of the flange. It measures the centre hole in the work. The steel blocks, B and C gauge the depth of the two faces from the flange. The part D gauges the large bore. All parts are fitted to the frame E after hardening, and ground on centres provided for the purpose.

Inspection Gauge.

Fig. 37 is a gauge used in the inspection room for gauging the diameter of a wrist pin hole in a piston. A straight edge is provided for determining if the hole is at right angles to the diameter of the piston.

Profile Gauge.

Fig. 38 shows a form of checking gauge used for gauging the profile of the work with its relation to the hole. The profile templet A is made of Ketos non-warping tool steel. A slot or kerf is milled in plug B to receive this templet. It is secured by means of three screws shown.

The gauge illustrated in Fig. 39 is not a plug gauge, but is well adapted for gauging the ring grooves in pistons and work of like character. The dimension W represents the width and (d) the depth of the groove.

Combination Gauge.

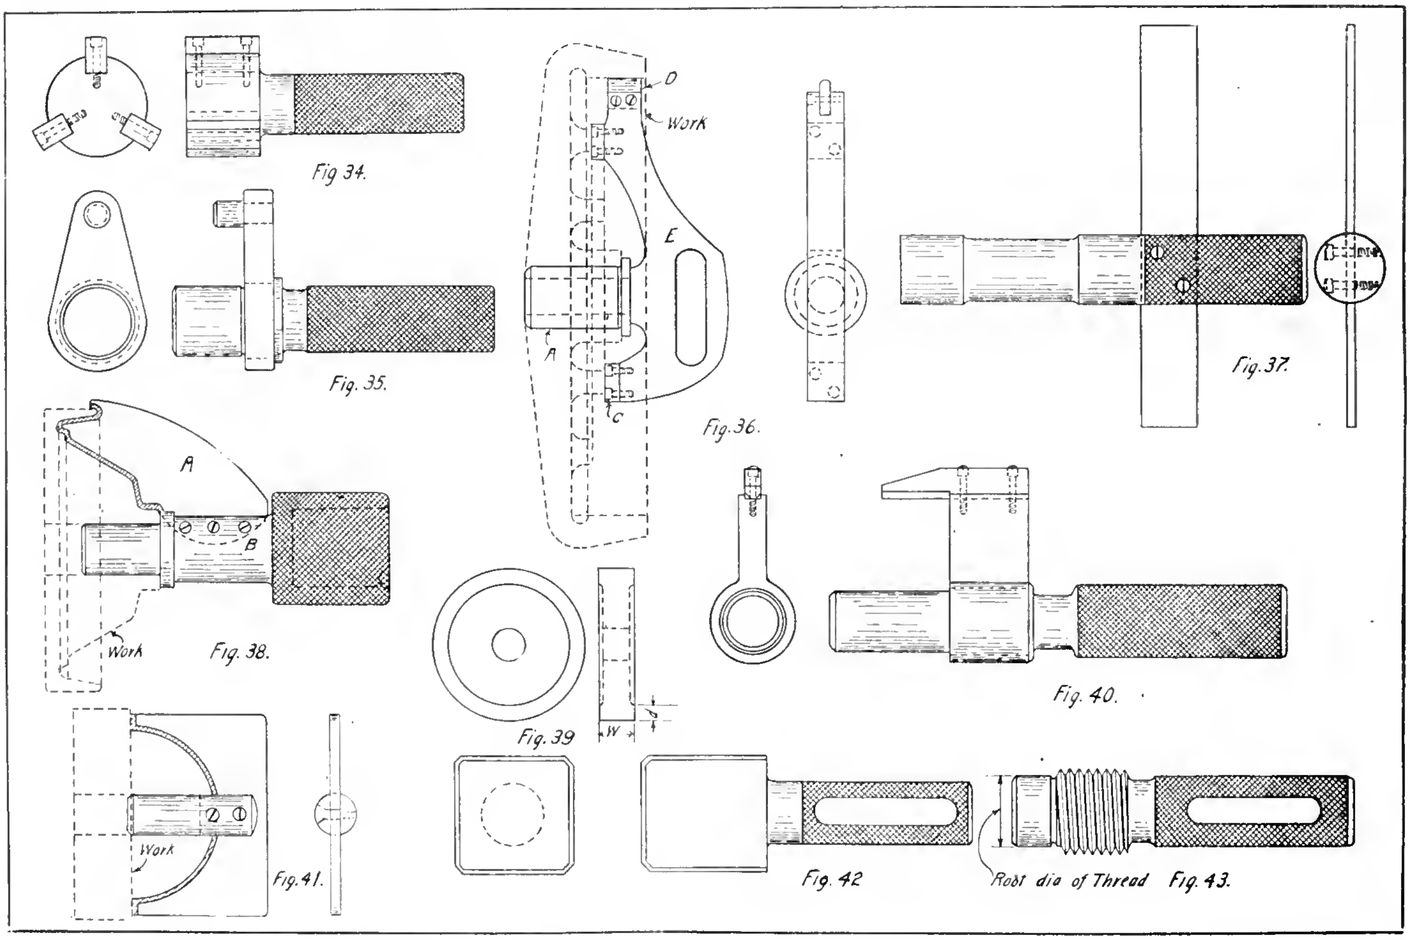
Fig. 40 is a combination of plug and snap gauge. It is used to advantage where a hole and outside diameter are to be gauged. This form of gauge should only be used when the limits on the outside diameter are not very close.

Fig. 41 is another plug profile gauge of almost similar construction as that described in Fig. 38.

Fig. 42 is a plug gauge for square holes.

Reference Gauge.

Fig. 43 is a standard reference gauge, and is only used in the tool-room for comparing with the shop gauges. They should not be hardened.



DESIGN AND CONSTRUCTIONAL FEATURES OF PLUG GAUGES.

Grinding Wheels: Their Material and Manufacture

The adoption of grinding as a commercial operation in machine shops has been very marked in connection with shell making. While most users are familiar with the suitabiliy of different abrasives for certain classes of work, the principal features regarding the manufacture of grinding wheels have always remained more or less unknown.

GRINDING as a means of removing metal has been brought to a state of such perfection and applied to such a broad field of manufacture that grinding machines excite no more comment than engine lathes or other manufacturing tools. The great advances made in the production of high-speed steel have monopolized the attention of manufacturers to so great an extent that the degree of perfection attained by the makers of grinding wheels has not been proportionately recognized.

The subject of grinding has received considerable attention from Mr. John Davey, of Glasgow, who recently read a paper before the Keighley Association of Engineers. The subject of materials and processes involved in the successful production of grinding wheels is treated by him in a most interesting way, and the information conveyed is certain to be appreciated by many users of abrasive products.

Abrasives: Natural and Artificial.

The principal natural abrasives are emery and corundum. The artificial abrasives are becoming increasingly numerous, and include carbolite, carborundum, crystolon, and alundum. These substances are all products of the electric furnace.

Emery.

Emery is simply corundum with a number of impurities present, which frequently accompany it in its natural state. Several years ago practically all grinding wheels were made from emery obtained from the vicinity of Smyrna and Chester, Mass., U.S.A. The value of emery as an abrasive depends upon the proportion of crystalline alumina oxide which it contains. This is the only element in emery which is hard enough to have any appreciable cutting action on metals.

Corundum.

Pure corundum was adopted in preference to emery. Being harder, the grains held their sharp points longer, while the absence of impurities, which caused increased friction without removing any metal, reduced the heat generated, thus allowing output to be increased.

Corundum has been obtained in India, and also in the States of Georgia and North Carolina, but nearly always in small deposits of varying quality. It would contain crystalline alumina to about 77 per cent. Due to its superiority over emery, it was eagerly sought after by the makers of grinding wheels. The supply from the sources mentioned was limited and uncertain, so that it did not come into general use until the discovery in 1896 of the now well-known Canadian mines. Not only do their deposits contain an unlimited supply of corundum, but the quality is far superior to any previously mined. It is found to contain 90 per cent. crystalline alumina and will often analyse much higher. Sharpness combined with just the right temper, has made Canadian corundum an ideal abrasive for most kinds of grinding. The Canadian corundum is mined in Eastern Ontario, the known deposits covering an area of about 32 miles long and 5 miles wide.

Carborundum.

Carbolite, carborundum and crystolon are different formations of the same substance; i.e., carbide of silicon.

Carborundum is distinct from anything found in nature. It is the product of the electric furnace, and being under human control, its freedom from impurities is assured. Carborundum is the trade name for carbide of silicon. It is the crystalline formation of the elements of carbon and silicon, brought about by subjecting a mixture of coke and sand to the inconceivable heat of 7,000° Fahr. The mixture is placed in the electric furnace, a fire brick structure 50 ft. long by 8 ft. wide, through which is built a core or resistance path. Leading to the core are the carbon rods attached to a set of power electric cables. To the mixture of sand and coke is added a quantity of sawdust which makes the mixture porous, so as to allow for the free escapement of gases which are found during the operation. When the furnace has been filled the electric current is turned on and travels along the core, generating a heat that really is beyond human comprehension. It is a temperature at which steel, marble, granite or the highest refractory substances would not only melt, but would vaporize. In this tremendous heat the element of carbon and the element of silicon fly together and form crystal masses of the most beautiful hues. It takes 36 hours for the crystal to form. At the end of 36 hours the outer crusts of the mixture are broken into, the crystal masses removed and taken to the crushing department. The grains are, then carefully washed free from dirt, dried and separated into the different sizes of grains.

Carborundum is particularly suited for foundry work and grinding cast iron in the cylindrical and surface grinding machines.

Alundum.

Alundum is oxide of alumina in crystalline formation. It is made by fusing the mineral bauxite to an intense heat in the electric furnace by the arc process. Chemically, bauxite is the purest form of aluminum oxide found in nature. The best bauxite mines are those found in the southern part of U.S.A., and only the best from these mines are used in the manufacture of alundum. Bauxite was considered infusible until the invention of the alundum electric furnace.

The furnaces used for the manufacture of alundum are different from the electric furnace used for the making of carborundum. They are conical-shaped pots, which stand on a car, and are heated by two vertical electrodes, which are gradually raised as the molten bauxite fills the furnace. The bauxite, as it is prepared for the furnace, is in the form of coarse gravel, that is, the bauxite as it comes from the mine is in a wet, clayey state. It is dried by means of a rotary calciner. The cylinder of this machine is 60 ft. in length, and is heated by two gas producers, the material being fed in at the farthest from the fire. Platforms are erected upon which the dried bauxite is placed, and it is fed into the electric furnace through the top.

Alundum is very suitable for use in the cylindrical and surface grinding machines for grinding hardened and soft steel, brass, bronze, etc.; in fact, it covers the same field as corundum.

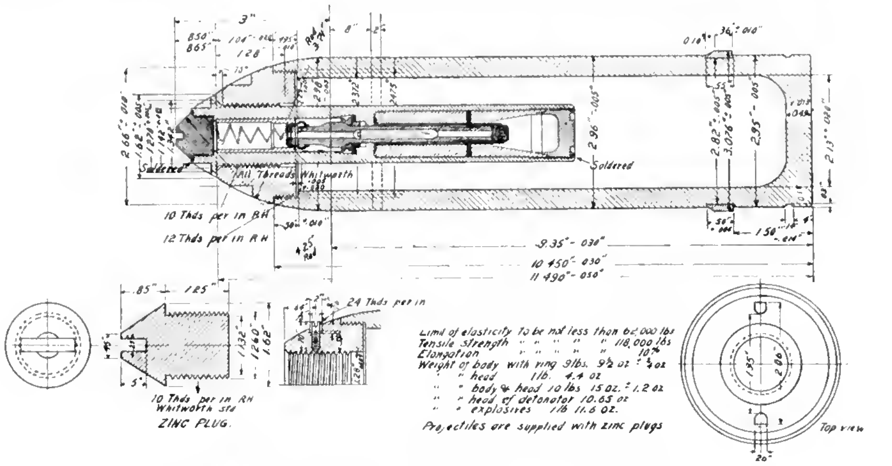
Three distinct processes are now widely employed for binding together abrasive grains to make grinding wheels. These are the vitrified, silicate and elastic, and each produces wheels specially suited for certain kinds of grinding.

Vitrified Process.

More grinding wheels are made by the vitrified process than any other. It consists in mixing suitable clays and fluxes in certain proportions with the grains of abrasive. This is generally done by the wet process, when a large amount of water is added and the mixture stirred in mixing kettles, until it is quite fluid. In preparing the mixture before the water is added, great care is taken to get the correct proportion of abrasive and the different clays, and in the case of combination wheels, where different size grains are used, the same precaution is used, so that wheels can be duplicated at any time. If an order is passed into the works for a wheel of a certain grit and grade it is made to the standard

formula. Some years ago a great deal of trouble was caused by the wheels varying, but by the use of improved methods and care in weighing out the correct proportions of abrasives and clays this has been reduced to a minimum.

After the mixing, the mixture is drawn off into moulds and dried in drying rooms until it is hard enough to be handled. The wheels are moulded larger than the size wanted, and are shaved off on a machine resembling a potter's wheel. The hole is also put into the wheel on the machine while the wheel is in its semi-finished state. The next process is placing the wheel in the kiln. The kilns vary in size, some containing a chamber 18 ft. in diameter and 8 ft. high. The wheels are placed on fire-brick tiles, then surrounded by fire-clay rings, until the stand is complete. The kiln will hold several hundred wheels. The period of burning varies according to the size of kiln. In the larger kilns it takes nearly three weeks from the time the kiln is charged until it is drawn. During the baking or burning process the temperature is gradually raised until it is hot enough to vitrify or partially melt the clay, about 3,000° Fahr. The utmost skill and care are required to successfully burn a kiln, and every possible device is used to bring the operation under perfect control. If the temperature is allowed to change too quickly the wheels will be cracked. If they receive too much heat they will be harder than intended, and if not enough they will come out too soft. Wheels made by the vitrified process are those mostly in use on cylindrical and surface grinding machines, as they are free cutting.

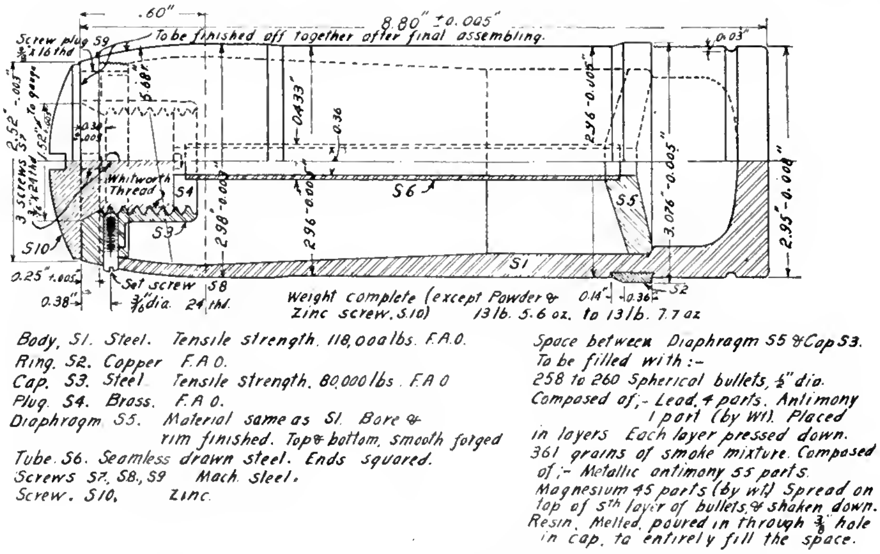


RUSSIAN 13½-PDR. HIGH EXPLOSIVE SHELL.

Silicate Process.

Silicate of soda or water glass is the principal ingredient in the bond of these wheels. After it has been thoroughly incorporated with the abrasive grains in special mixing machines, the whole mass has a thick adhesive quality. In this condition it is rammed into moulds. This part of the work requires considerable skill, and the uniformity and balance of the wheels depend largely upon the skill of the moulder. The wheels are then dried and afterwards baked in special ovens, from which all fire gases are carefully excluded. This causes a chemical reaction, which hardens or sets the bond, and after sufficient cooling, the wheels are ready to go to the finishing room. Some shapes of silicate wheels are moulded under hydraulic pressure, as, for instance, dish wheels, and all very hard silicate wheels are so moulded.

Water glass is the principal ingredient in the bond of silicate wheels, but other substances have to be added. Wheels made by this process are used for cutter sharpening, tool grinding, such as lathe and planer tools, etc. They can be furnished in a few days, and can be made up to 60 inches diameter or more, which is not possible in the vitrified process.



RUSSIAN 15-PDR. SHRAPNEL SHELL WITHOUT FUSE NOSE.

Elastic Wheels.

Shellac is the principal ingredient of the bond of elastic wheels. After the mixture has been suitably prepared, its consistency is such that if thin wheels are wanted it may be rolled into shallow moulds. Thicker wheels are moulded under hydraulic pressure or rammed into moulds the same as silicate wheels. They are then baked at a low temperature to set the shellac. By the elastic process very thin wheels may be made and used with safety. Wheels as thin as 1/32 inch are procurable, and are very useful for cutting of small bars of high-speed steel. Wheels made by this process can be supplied in a few days. All wheels require to be more or less finished after the baking or burning process. This work is done in special lathes, using a circular steel cutter and other types of wheel dressers. After finishing, the wheel is mounted on balancing ways. If not in balance, it is made so. It is then revolved at a speed 60 per cent. in excess of its working speed, producing a stress more than twice as great as that developed in use.

The wheels are tested for hardness by using a sharp-pointed instrument and comparing them with master discs that are kept as standards.

H. L. Gantt says scientific management will reduce costs, or, what is its equivalent, the time and effort necessary to do a certain amount of work, but it will not solve the labor problem; it will not in the long run tend to raise wages or increase profits. Scientific management is suffering more from the fact that too great claims are being made for it than from anything else. Far more fundamental reforms are necessary.

When opening up any steam line, take the following precautions:—(1)—Open all available drips. (2)—Warm the line by opening the stop valve sufficiently to warm slowly. (3)—Never allow an inexperienced man to turn steam into a cold line. (4)—Never open the main valve until certain that the line is thoroughly heated.

Principles of Laying—Off Cylindrical Intersections---II.

By J. W. Ross

The more or less special nature of the work involved in the making of sheet metal piping has caused many manufacturers to avoid this class of work, with the result that when a job has to be handled, there is frequently considerable unnecessary loss incurred through errors in laying off material. The examples treated by the writer of this article should form a valuable reference to many manufacturers on ordinary as well as special occasions.

HEAVY PLATE TEE.

FIG. 1 shows in perspective a Tee which it is proposed to develop in heavy plate. The front and side elevations are shown in Figs. 18 and 19 respectively. The measurements will be given in feet, the student reducing the dimensions to any desirable scale.

Construction.

Measure off C D Fig. 18 equal to 91 inches. Draw the lines A C and B D at right angles to C D, and equal in length to the outside dia. of the pipe which is 37 inches. Draw the line A B parallel and equal in length to C D. C A B D shows the side elevation of the horizontal cylinder.

Bisect A B at L, and raise the perpendicular J L 10. Measure off L 10^1 equal to 22 inches. Through and with 10^1 as centre, draw the line 7^1, 10^1, 1^1, at right angles to the line L 10^1, and equal in length to the neutral diameter of the pipe which is 36½ inches. Project the points 7^1 and 1^1 down at right angles to A B, locating the points 7^2 and 1^2 respectively. Connect these points which will show the neutral outline of the vertical pipe. Build around the neutral lines 7^1, 7^2, 1^1, 1^2, the cross section of the plate thickness. With O as centre describe the neutral plan view of the vertical cylinder. Divide this circle into a suitable number of equal spaces. This number to be at least divisible by four as was previously explained to show lines on each quarter of the circle. The greater the number of spaces the more accurate the developments. To save confusion of the lines in such a small drawing the number 12 has been chosen. Project all these points, parallel to 10, J, and down through A B, indefinitely. Now construct the end elevation view. Draw the centre line 7, E, Fig. 19 parallel to the centre line 10, J, Fig. 18. Project the line A B, Fig. 18 over to its intersection of the centre line 7 E, Fig. 19, thus locating the point 7^2. Locate the point E by projecting the line C D Fig. 18 over to the centre line 7E, Fig. 19. With centre K and radius K E describe the circle representing the end view of the outside circumference of the horizontal cylinder A B D C. Project the line 7^1 10^1 1^1, Fig. 18 over to 4^1, 1^1, 10^1, Fig. 19. With centre O^1 and radius equal to half the neutral diameter of the vertical pipe draw the circle 1, 4, 7, 10. Divide into 12 equal parts. This plan is shown as a quarter turn to that of the plan view in Fig 18. Therefore number accordingly. From all these located points drop projectors—parallel to 7 E—to the intersection of the horizontal end view. Number all these intersections in relation to the plan view. With K as centre, draw in the neutral circle line and thickness of the plate for the horizontal cylinder. Also build up the plate thickness around the neutral lines 4^1 4^2 and 10^1, 10^2. Horizontally project the points 1^2, 2^2, 3^2, 4^2, etc., Fig. 19, to their intersections of the similarly numbered vertical projection lines in Fig. 18. In this manner locating the mitre points by the points 1^2, 2^2, 3^2, 4^2, 5^2, 6^2, etc., Fig. 18. Connect these points by an even curve thus defining the mitre line. With ¾ inch radius draw in the neutral line as at the points 1^2 and 7^2, Fig. 18. With ½ inch and 1 inch radii draw the cross sectional plate thickness. Draw in the laps. Locate the laps as F and G, Fig. 18. Similarly draw in the flange, rivet, and lap allowances as shown by H in Fig. 19. Now proceed to develop the vertical pipe.

The neutral diameter equals 36½ inches. The stretchout equals 36½ × 3.14 which is 114.61 inches or nearly 114⅝ inches. Measure off 1^1, 7^1, 1^1 Fig. 20 equal to 114⅝ inches. Divide into 12 equal spaces. Project these points downwards. Number with the object in view of having the vertical rivet seam on the lines 1^1, 1^2—1^1, 1^2. Now set the dividers to the distance 1^1, 1^2, and 7^1, 7^2, Fig. 19. Transfer this over to this numbered element lines in Fig. 20. Proceed in a similar manner by transferring the distances 2^1, 2^2, 3^1, 3^2, 4^1, 4^2, Fig. 19 to their respective locations in Fig. 20. In transfering these measurements ignore the flanges at F and G, Fig. 18, and H, Fig. 19. The reason for this is as follows:—4^1, 4^2, Fig. 19, is drawn without the flanges, the neutral line striking the circle as shown at 4^2. On the line 10^1 10^2 the flange is shown, and the neutral line is drawn in its correct relation to the plate thickness. To transfer 10^1 10^2 take the measurement as was done for 4^1 4^2. Draw an even curve through these located points on Fig. 20. This is shown drawn with short dash lines. This line would be the flange line in light plate. In heavy plate this line will change according to the thickness of the plate used. The plate thickness in the drawings Fig. 18 and 19 is somewhat exaggerated for explanatory purposes. Again to show it more clearly, the section of plate on the line 1^1, 2^2, Fig. 18, is enlarged in Fig. 21. In Fig. 21 the inside

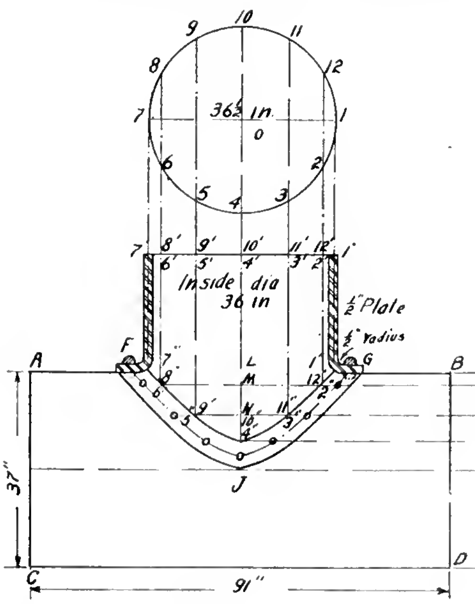


FIG. 18.

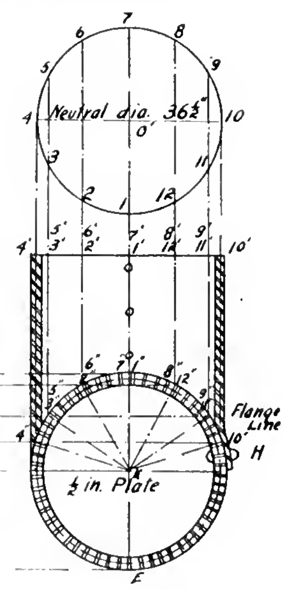

FIG. 19.

*Note: The reference letters and numerals in the text, i.e., G^2, 7^2, etc., correspond with those of the illustrations indicated as G", 7", etc.

radius of the bend is ½, therefore the neutral radius will be ¾ inches. R locates the centre for this radius and P and S the extremities of the quadrant. Bisect this quadrant at Q, thus locating the centre of the flange. Measure carefully along the neutral line the straight as well as the curve from 1^1 to Q. Take this distance and transfer it over to the line 1^1 1^2 Fig. 20, to locate the point Q, for the flange line of the templet. Again measure from Q to the centre of the rivet, and also from the rivet centre to the edge of the lap Fig. 21 transfer this also to the rivet line 1^1 1^2 Fig. 20 to locate the rivet line on the flange and the lap edge. These dimensions may be calculated. The neutral radius R, P, multiplied by 1.57 will give exactly the length of the neutral quadrant P Q S. R P equals ¾ inch, and ¾ × 1.57, equals slightly over 1⅛ inches, which is the length of the neutral quadrant P Q S. Now 1^1 P equals 22 inches minus the ½ inch for radius and the ½ inch for plate thickness, which equals 21 inches. P Q equals ½ of P Q S — 9-16 inches. Therefore 1^1 P, plus P Q, equals 21 9-16 inches. This dimension being equal to 1^1 Q in Fig. 20. Also Q S which equals 9-16, plus 1¼ inches to the rivet centre, plus 1¼ inches to the edge of the lap equals 3 1-16 inches total.

Q G, Fig. 21 therefore equals 3 1-16 inches. Measure off 7^1 Q G equal to 1^1 Q G Fig. 20. Refer back to Fig. 19. Measure along the neutral line the distance from 10^1 to the flange line Q and from Q to the rivet centre, and from the rivet centre to the lap edge, transfer these measurements to Fig. 20 on the lines 4^1 Q H and 10^1 Q H. With the five points Q located, draw in the flange in relation to the mitre line also draw in the rivet line and lap edge. Space off the rivet centres into a suitable number of equal spaces. One of the corners is scarfed, that is, thinned down, to permit of a close fitting joint at this point when the plate is rolled and fitted into position. As was stated before it is not the usual practice to put the holes in this templet. These holes being marked off when fitted on the rolled up horizontal cylinder.

The opening and the rivet holes will now be marked off in the cylinder as shown in Fig. 22. Calculate the stretchout of the horizontal cylinder of which the neutral diameter equals 36½. The stretchout equals 36½ × 3.14 which is nearly 114⅝ inches. Measure off D B D Fig. 22 equal to 114 ⅝ inches. Bisect to locate B, erect the perpendiculars B A, D C, and D C equal in length to that of D C Fig. 18. Draw the line C A C parallel to D B D. Draw radial lines from the points 1^2, 2^2, 3^2, 4^2, 12^2, etc., Fig. 19, to the centre K. Note where these radial lines intersect the neutral line of the cylinder of which K is centre. Transfer all these distances from these points measured along the neutral line as 1^2 to 2^2, 2^2 to 3^2, etc., Fig. 19, to the distances 1^2, 2^2, 2^2, 3^2, etc., on the line C A C, Fig. 22. Through these points Fig. 22 draw

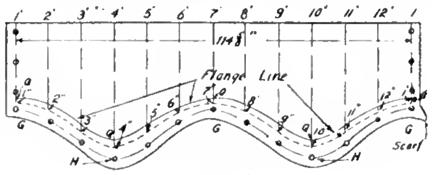

FIG. 20.

lines parallel to the centre line A B. Number these points and lines corresponding to the points from which they were transferred. Bisect C D at J and draw in the horizontal centre line J J. Locate L Fig. 22 at the intersection of J J with 1^2 7^2. Locate M at the intersection 2^2 6^2 and 12^2 8^2. Similarly locate N. Take the distance L to 1^2 on the mitre line Fig. 18, transfer this to L, 1^0 Fig. 22. Again

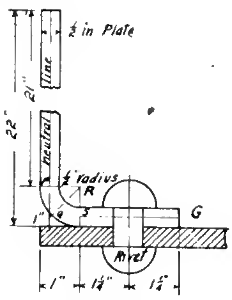

FIG. 21.

take the distance M 12^2 Fig. 18, and transfer over to M, 12^0, Fig. 22. Similarly transfer the remaining distances N, 11^2, N 3^2, L 7^2, etc., from Fig. 18 to their respective positions as N, 11^0, N 3^0, L 7^0, etc., Fig. 22. Connect all these points with a fair curve thus locating the outline of the opening. Take the distance 1^2 to the rivet centre at G Fig. 18 and measure this off to locate the rivet centre on the line 1^2 7^2 by measuring

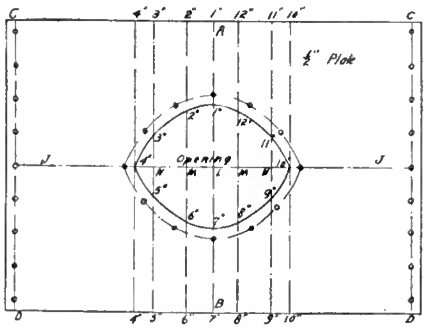

FIG. 22.

from the points 1^0 and 7^0. Similarly locate the other points for the rivet line. Draw in this line and space off the rivets equally. Space off the rivets equally on the seams C D, so that when the plate is rolled up all the holes will come fair. This completes the templet. The method in this problem of drawing the plate thickness is applicable to the preceding as well as the following problems when dealing with heavy plate.

PACKING HYDRAULIC JACKS.

HYDRAULIC jacks sometimes fail to develop full capacity, or settle slowly when left standing under a load, without apparent reason. Such failures, says the engineering department of the Travellers' Insurance Co., are commonly due to defective packing. These defects are first evidenced by the failure of the jack to raise or hold the load, and, when this is noted, the jack should be examined to find out where the packing failed to hold. The leakage at the defective point is readily detected. A prominent manufacturer of hydraulic jacks makes these recommendations with regard to the valves and their seats:—

If the packing is in good order and the ram does not rise in pumping the suction valves are not working properly. If the lever rises when the hand is removed, the pressure valve is not working properly. If the valves or their seats become worn or scratched, grind them to a fit with oil and a little flour of emery. Be careful not to grind them too much, and be sure to wash the valves and their seats perfectly free from emery before putting the jack into service again. If the valves are deeply scored or have become too much worn, replace them with new ones, and grind new ones lightly to their seats, as described.

Short Circuits usually come on slowly, and discriminating protective gear and quick-acting circuit breakers should be a sufficient safeguard to the station without the use of reactances. While it is quite true that discriminating protective gear may do much to increase the safety factor of the system, the fact remains that "dead" short-circuits will sometimes occur, and that in such events no switch or relay is sufficiently quick-acting to open the circuit breaker before the rush of current has occurred. Furthermore, no discriminating gear can protect the generator in the event of a misphase, and it is well known that the strain on the generator may be greater in the event of a misphase than if the generator short-circuited directly across its terminals.

If a man works for you, Mr. Employer, have confidence in him. If he be not deserving of your confidence discharge him at once. Suspicion and aloofness never helped any fellow in any situation.

MAKING SPRINKLER TAPS.

By F. M.

THE growing use of water sprinklers for fire protection has brought out a special style of short tap for threading the connection shown in Fig. 1. A sketch of the finished tap is shown in Fig. 2.

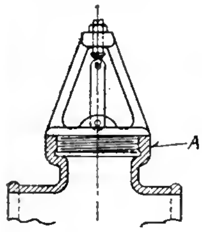

FIG. 1.

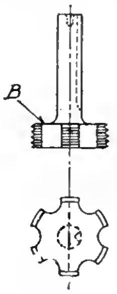

FIG. 2.

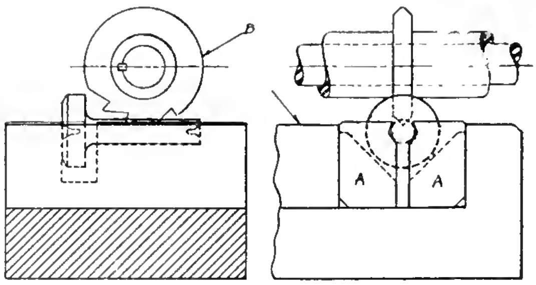

FIG. 6.

MAKING SPRINKLER TAPS.

To facilitate the operation of rough turning on these taps, when made in large quantities, the stock is prepared so that all the heavy turning is performed in pairs before finishing.

The first manufacturing operation is the cutting to length, which is done in a rotary saw, as shown in Fig. 3. Six bars are placed in the vee clamps and are cut off to a length, equal to twice that of the taps plus the width necessary for parting, after they have been rough turned.

After cutting to length, the pieces are centered on each end in the centreing machine shown in Fig. 4. The work is held in a central position by means of the vee blocks C and fed to the combination centre drill A, by means of the swinging lever attached to the tail stock spindle. The piece B, also shown in Fig. 5, has a knurled cup centre inserted, which takes the place of a dog to prevent the work from turning while being centred.

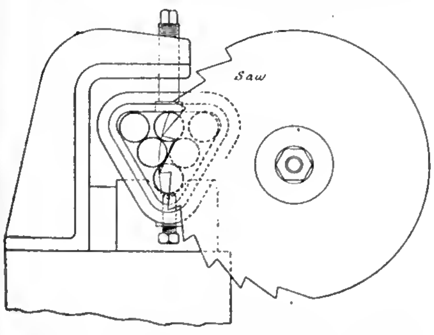

FIG. 3. MAKING SPRINKLER TAPS.

The pieces are next placed in a lathe and rough turned alternately on each end until within 1-32 in. of the finished sizes. The rough turning having been completed, the pieces are parted, the burr ground off and the ends centred. They are then turned in successive operations of, face shoulder (leaving large fillet for strength), turn shank, turn for thread, chamfer, mill the groove, cut the thread and mill the flutes. The milling of the groove in the shank is performed in the jig shown in Fig. 6. The two steel vee blocks A A are held in the vise, thus gripping the shank of the tap and leaving room at the top for the cutter B to mill the groove.

When threading the taps, a shoe is placed in the milled groove in the shank to prevent slipping. After threading, the flutes are milled to form the tap. The lands are then backed off and the tap hardened and ground. The hardening was done by heating the taps in a lead bath to the proper temperature and quenching them in water or oil. After tempering the shank was ground and also the flutes with a formed wheel.

REPAIR TO A SPUR GEAR.

By J. McCormack.

SOME time ago I observed the following repair made upon the broken teeth of a spur gear. Holes were drilled where the teeth had been, care being taken to retain the proper position. The holes were tapped of a size to suit the thickness of the teeth in the gear. The rod stock was threaded with an adjustable die and made sufficiently over-size to be a tight fit in the tapped hole. The pins were placed a little more than their own diameter apart and directly in line with the corresponding pin in the row ahead. Those in the pinion were placed to correspond with those in the gear to prevent uneven contact. This repair, although fairly serviceable, was only temporary, new gears being secured within a few days.

COST KEEPING IN SMALL WORKS.

By M. B. Saunders.

THE one great trouble that the manager of the small jobbing shop has is to be able to keep a really accurate system of costs, without having a large staff to handle it. The following is an outline of a cost system used in a small shop, doing a very great variety of repairs, as well as a small amount of manufacturing.

Numbered order sheets A, are kept in the office, and when a job comes in, the name and details are entered in duplicate by means of a piece of carbon paper on the right half of the form A: the part marked A1 being torn off and given to the foreman. The large part A, being then put in a loose leaf binder and kept

in the office as a record of the job including all details as supplied to the foreman.

Ref. order left by Master Mechanic.

Make new piston rod for 8"x12" hoist. (as sample supplied)

Date Finished

All Material used on this Job must be Entered on this Sheet.

A1

COST KEEPING IN SMALL WORKS—ORDER SHEETS.

Now to follow this order right through to completion we will suppose it calls for a new piston rod for an 8 in. x 12 in. hoist. The foreman takes the job to a man, explaining what is necessary, and gives him a job card, Fig. B, and punches the time he starts, also if material is required; when material is required the foreman enters the particulars upon the back of the card.

Later during the day the man reports that the job is completed. The foreman having inspected it, punches the card at the stopping time and drops it in the box provided at the office.

In order to check up the number of productive hours during the day, the workman's time sheet, Fig. C, simply call for him to fill in his name and date, time he starts and leaves his work.

DATE Dec. 10th.

COST KEEPING IN SMALL WORKS—WORKMEN'S TIME SHEET C.

The next morning the cost clerk takes all the time sheets and job cards to his desk. First he enters the number of hours and material up to the various factory order numbers and then takes each man's time sheet and marks upon it the f.o. numbers: the time on these should correspond to the hours marked opposite which the man expects to be paid for.

When this system was first installed by the writer, errors were found, showing where a man had 9 hours on his time sheet and only 8 hours on his job card,

COST KEEPING IN SMALL WORKS—JOB CARD B.

thus giving an accurate record and also a check upon the time wasted between the finishing of one job and the starting of another. Also when a man starts at 7 and his job card shows him starting a job at 7.30, it indicates delays that become costly to the management.

Any number of job cards can be used during the day—one card for each job—and if a job is stopped before finishing and then gone on with the record can be kept on the same card, thus 7 to 11 and 3.30 to 5.15.

When the cost clerk receives the slip A, back from the foreman he knows the job is completed, can transfer his order A to his completed file and invoice the customer in the usual way.

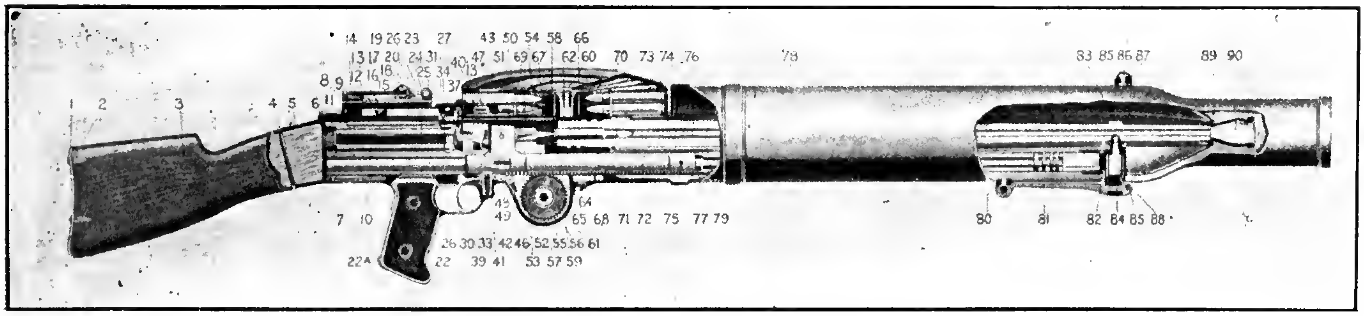
This system at first sight may seem complex and hard to operate but the writer has found that after a few days everything works smoothly.

CONTEMPORARY WAR ARTICLES

Embracing Information and Data Drawn from a Variety of Sources Relative to and Arising from the Prosecution of this Many-Sided European War

THE "LEWIS" AUTOMATIC MACHINE GUN.

THE machine guns which the Ontario Government will supply to our overseas forces at a cost of $200,000, might rather be termed rifles. The official name of the weapon is "The Lewis Automatic Machine Gun." It weighs only 25 pounds without its tripod support, which is four and a half pounds in weight. Thus the whole gun may be carried about by one man, and operated by one man, without difficulty. A powerful man may even use the weapon from the shoulder, as though it were an ordinary rifle. One gun can fire 440 rounds per minute, including the time necessary to change magazines, each of which contains 47 rounds. It is in operation in the French and Belgian trenches at the present time, and is somewhat similar to a Hotchkiss automatic rifle employed by the French.



THE "LEWIS" AUTOMATIC MACHINE GUN

1—Butt plate. 2—Butt plate screws. 3—Butt. 4—Butt tang screw. 5—Butt tang. 6—Feed cover latch. 7—Butt latch, securing butt to receiver. 8—Back sight bed spring. 9—Back sight bed spring screw. 10—Butt latch spring. 11—Back sight bed. 12—Feed cover latch pin. 13—Feed cover. 14—Back sight leaf. 15—Back sight thumb piece. 16—Back sight slide catch. 17—Back sight fine adj. worm. 18—Back sight fine adj. worm axis pin. 19—Back sight slide catch spring. 20—Back sight slide. 22—Firing hand grip. 23—Back sight axis pin washer. 24—Back sight axis pin. 25—Back sight axis washer fixing pin. 26—Receiver. 27—Magazine pawls spring. 30—Trigger. 31—Feed operating stud. 33—Trigger pin. 34—Feed operating arm. 37—Bolt that closes breech and takes shock of discharge. 39—Guard. 40—Cartridge guide spring. 41—Sear spring. 42—Sear. 43—Magazine pan. 46—Gear stop. 47—Striker fixing pin. 48—Gear stop pin. 49—Gear stop spring. 50—Striker. 51—Cartridge spacer. 52—Gear operated by main spring. 53—Main spring casing. 54—Magazine top plate rivets. 55—Main spring which closes breech and returns parts to firing position. 56—Collet pin. 57—Main spring collet. 58—Magazine center. 59—Main spring rivets. 60—Magazine latch spring. 61—Gear casing. 62—Magazine latch. 64—Gear casing side piece. 65—Gear case hinge pin. 66—Feed operating arm latch. 67—Magazine top plate. 68—Receiver lock pin. 69—Cartridge spacer rivets. 70—Interior cartridge separators. 71—Radiator casing rear, locking piece. 72—Rack, actuated by piston and main spring. 73—Radiator casing rear, platform. 74—Radiator casing rear. 75—Piston connecting pin. 76—Barrel. 77—Gas cylinder. 78—Radiator for cooling barrel. 79—Piston operated by gases of exploding cartridge that ejects empty shell and resets firing pin. 80—Regulator key stud. 81—Gas regulator key. 82—Gas chamber. 83—Gas port. 84—Gas regulator. 85—Clamp ring. 86—Fore sight. 87—Clamp ring positioning screw. 88—Clamp ring screw. 89—Barrel mouth piece. 90—Radiator casing front.

The Lewis gun is designed in such a manner that the only tool necessary to dismantle it completely is an ordinary service cartridge, the point of whose bullet is used to disconnect every portion of the mechanism; and this operation is such a simple matter that the gun can be "knocked down" and any small damaged part replaced, well inside five minutes. The weapon takes the service ammunition, and its range is similar to that of the service rifles. When used on a fixed mount the butt stock may be removed and a "spade handle" substituted.

Constructional Features.

The gun is of very ingenious construction. A detachable magazine loaded with 47 cartridges is attached to a suitable fixing on the barrel near its rear end, the first cartridge being fed from the magazine into the firing chamber by the first forward movement of the firing pin, which is, however, arrested before the striker reaches the cartridge unless the trigger is held back. When the trigger is pressed, the striker, carried forward by the mainspring, explodes the cartridge in position in the firing chamber.

Before the bullet leaves the barrel under the influence of the gas pressure, it uncovers a hole connecting the barrel with a cylinder below and lying parallel with it. A portion of the gas passes into the lower cylinder, driving back the piston, and with it, the rod against the pressure of the mainspring. The movement of the rod recocks the gun, throws out the exploded cartridge case, and during the early stage of its return journey, under the mainspring's influence, transfers a live cartridge from the magazine to the chamber.

If the gunner lets go the tripper the firing ceases, and the gun remains cocked until the trigger is again pressed; if, however, he keeps a continuous pressure on the trigger, the weapon continues to fire until all the cartridges in the magazine are exhausted, the rate of continuous fire being as high as 440 rounds per minute, including the interval occupied by replacing empty magazines with loaded ones.

Dissipating Barrel Heat.

The dissipation of the intense heat developed by the almost continuous combustion of explosive charges in the barrel of the machine gun presents a somewhat difficult problem, and failure to accomplish this efficiently causes the barrel to become red hot and prematurely to explode the incoming cartridge. The barrels of the Lewis and the Hotchkiss guns are both cooled by means of ribs which radiate the heat into the atmosphere, those of the Lewis being placed longitudinally and contained in a steel casing, through which cool air is drawn by the "exhausting" effect of the powder blast in the muzzle end of the casing, in the same way that the air is drawn through the fire-box of a locomotive by the blast of the exhaust steam in the chimney.

Recoil Feature.

The recoil on the Lewis gun is counter-balanced in a very simple and ingenious manner, the gas from the discharge being directed by means of a cone attached to the muzzle of the barrel proper, on to the inner surface of the casing, so that the friction between the gas and the metal casing tends to carry the gun forward with the stream of gas, and so

counter-balances the force of the recoil acting in the opposite direction.

The mainspring of the Hotchkiss gun takes the form of an ordinary coil-spring acting in compression situated in the cylinder underneath the barrel; whilst the same unit in the Lewis is a spring of the type used for the mainspring of a watch, but naturally of a much greater power. This spring is coiled up in a circular case attached to the gun just in front of the trigger, in a position sufficiently far from the barrel to be unaffected by the heat, and, consequently, in no danger of losing its temper from overheating. The Hotchkiss mainspring acts directly on the piston rod, which it surrounds; whilst the Lewis is coupled to its rod by a rack and pinion.

The magazine of the Lewis gun is circular in shape, the forty-seven cartridges with which it is loaded lying radially in two layers with their bullets pointing toward the centre.

MODERN MUNITIONS OF WAR.

AT the Royal Society of Arts recently, Professor Vivian B. Lewes delivered the first of a special course of three lectures on the subject of "Modern Munitions of War." The particular branch dealt with was "Guns and Propellants." The remaining lectures on "Mines, Shells and High Explosives" and "Poison Gases and Incendiary Bombs" were given on July 14 and 21 respectively. Sir Boverton Redwood was in the chair, and in introducing the lecturer said that in view of the diabolical ingenuity with which the enemy is carrying on this policy of frightfulness, it was well that the public should be enlightened upon the subject of munitions.

Professor Lewes said: Looking over all the wars we had been engaged in, it would be found that the cry had always been the same. In the Napoleonic wars our troops were crying out for shot and shell. Later, in the Crimea, fodder and food were required in addition to shot and shell, and in the South African War it was really the compartively small amount of ammunition that was required which prevented us being in terrible trouble then. When the history of the present war comes to be written when we have cooled down somewhat and see things in their true perspective — the most wonderful thing of all will be that our supplies of ammunition have been so remarkably good, and that in this war the ammunition supply had been far superior to what it had been in any other war we had ever waged.

Progress in Guns.

As showing the immense strides that have been made in guns and propellants, the lecturer drew attention to the fact that in the Napoleonic wars the old Victory had a broadside of fifty-two guns, and if the whole of that broadside was fired at once the weight of metal thrown was only 60 per cent. of the weight of one shell thrown by the 15-in. guns of our present super-dreadnoughts.

The next development was to rifle the guns, which gave increased range and greater accuracy. Then it became necessary to lengthen the guns in order to get the best effect of the rotation due to the rifling. This progress continued, and by the time of the bombardment of Alexandria in 1882, the smallest gun was double the size of the biggest gun in the Crimea. The old Inflexible in 1882 had four 80-ton guns, 16-in. calibre, an inch bigger than we have to-day, and by 1886 the size had increased to 110 tons, with a calibre of 16.25-in. using a charge of 960 lb. of powder.

Progress in Explosives.

Since that time an enormous increase had taken place in armaments which was accompanied by a very great change in our explosives. In the Crimea, with the 68-pounders, "rifle large grain" powder was used, but after the rifling of the guns was adopted and the guns were lengthened, it was found that this powder occasioned too great a stress on the breech of the gun, coupled with too low a muzzle velocity. To remedy these defects what was known as "rifle indent powder" was used, but this proved to be too expensive, and the Government found a way out by manufacturing what was termed "pebble" powder, the "pebbles" being gradually increased in size until they reached 1¾ in. cube. The desideratum was slow-burning, with a constantly increasing pressure, and "pebble" powder was not altogether satisfactory.

For many years this was an enormous trouble, until General Rodman, of the United States, suggested large solid cartridges with holes from end to end. The explosion passed through these holes, which gave the larger surface necessary to give the increased pressure of gas. It was a beautiful suggestion, but absolutely impracticable owing to the difficulty of obtaining uniformity in density in the powder, and the liability of the cartridge to crack. The idea, however, was put into practical form in prism powder. In this, the powder was made up into prisms with holes in the centre, and as large a cartridge as was desired could be built up in this way.

Smokeless Powder and Gun Cotton.

The next trouble that arose was the enormous quantity of smoke given off, both by rifle powder and prism powder, and it was quickly realized that a smokeless powder was a necessity. In this connection a long line of interesting researches had been carried out in the earlier years of last century. Brief reference was made to the work of Brockenau and Pellews, two French chemists who laid the foundations for the development of smokeless powder. Following this came the discovery of gun-cotton by Schonbein, the Swiss chemist.

Professor Lewes went on to mention the mysterious explosions in various countries which occurred within the next two years, and the complete abandonment of gun-cotton for a time. Meanwhile, the use of gun-cotton was kept alive by the discovery that a lower form of it could be manufactured by using a weaker solution of nitric acid. Subsequently, General von Lenck, of Austria, discovered the true cause of the earlier failures, viz., that as the gun-cotton consisted of fibres acting as minute tubes, these, in spite of washing, retained a certain small quantity of nitric acid. Hence the explosions when the gun-cotton was packed. This having been settled beyond doubt, the quest for a smokeless powder took everyone back to gun-cotton, rendered safe as we now know it, and the man who had never really got the credit for the discovery of converting gun-cotton into a smokeless powder was Dr. Walter Reid, who discovered a smokeless sporting powder.

At the present time nearly every country was making a descendant of this powder of Reid's as their service explosive. The Austrians, Germans, Russians and French were all using nitro-cotton powders, although we ourselves were using nitro-glycerine powder, for the reason that our service powder had to stand the climate of all parts of the world. At the same time it was so unstable that its use per se was extremely difficult and had to be safeguarded by all sorts of restrictions. The German navy, however, used nitro-glycerine powder on account of its smaller bulk and consequent lesser storage space required.

Nobel found that by mixing collodion with nitro-glycerine a gelatine body was obtained. He called this blasting gelatine, and this was still the finest mining engineering explosive in the world. Furthermore, Nobel had noticed that a mixture of nitro-cotton and nitro-glycerine tamed down the exuberant properties of both, and, together with General Hess, of the Austrian army, obtained a wonderfully fine smokeless powder by mixing it with camphor. Later on, however, Sir Frederick Abel and Professor—now Sir James Dewar found that a more powerful and suitable powder could be obtained by blending true gun-cotton and nitro-glycerine. They were mixed by means of acetone, which was afterwards evaporated off, and the result, to which 5 per cent. of vaseline was put in as a lubricant for the gun, was the smokeless powder known as cordite.

WAR ORDERS AND STOCK MARKET SPECULATION.

ARISING out of the war, business in many spheres of industrial enterprise has been—to put it mildly—stimulated. Metal working plants are particular beneficiaries, although, as regards the personal equipment feature, many other sections of our manufacturing community are experiencing an almost equivalent boom.

A few month's ago, Sir George E. Foster, Canadian Minister of Trade and Commerce in the course of an eloquent address before Ward Three Conservative Association, Toronto, hazarded the opinion that before peace again reigned "this war would sadden us and make us a more serious people, and would teach us that there is something more to live for than mere business, speculation and pleasure."

We are somewhat at a loss as to the popular classification of his then prediction, in a word, whether it were viewed from the standpoint of its avowed intention—the optimistic, or its opposite—the pessimistic. However it be, recent happenings give clear indication that Sir George was all wrong in attributing either sadness or seriousness as our portion of the grim struggle. Each succeeding month of the war duration appears to have been getting us just that much further away from the dual state referred to, and through the increasing demand for war munitions and supplies, is making us to all intents and purposes oblivious of our real individual place and part in the issues at stake.

Patriotism, Sir George made very clear, means sacrifice and not its commonly experienced substitute—skilfully masked service to our individual profit. If we would judge, however, by the wild speculation which has prevailed for several weeks in prominent industrial stocks, it is quite apparent that the attempt to make personal profit out of real or imaginary war order business is the primary and all-important consideration. All of this is, of course, a sure menace to legitimate business, and of necessity must be reckoned with sooner or later.

Men who have been observers of Wall Street for half a century say that while there have been manipulations in the past, those now being carried on are more open than any ever before perpetrated. What is true of Wall Street is equally true of our Canadian stock exchanges.

Industrially, and as a matter of fact in every department of our national life, we have for quite many months suffered severely from excesses of a similar nature. The convalescing process has been a long and trying one, and such as might at least have been expected to breed caution in the future. Not so, however; the war has provided the opportunity and excuse whereby stocks and shares of our industrial enterprises may be deliberately manipulated so that their price be forced up to figures altogether foreign to their value, and so that an unsuspecting public in its thousands and tens of thousands be fleeced and absolutely ruined. The hardships engendered by the excesses and speculation practised in the few years preceding twenty months ago will be but a mere bagatelle when compared to what may be expected when this war order stock speculation comes, as it certainly will to its logical and disastrous end.

We make complaint that much of the war order business that should have been ours has been placed in the United States, and we are not satisfied because of the apparent lack of further and greater consideration being given us in the matter of orders, in the filling of which we have shown ourselves to be fully competent. More war contracts placed, if simply made an excuse for stock manipulation instead of being considered the legitimate business of our Dominion, will in the nature of things contribute little of blessing to our people but much of curse.

Public opinion was never in our history in more need of being aroused than it is to-day relative to stock market gambling in Canadian "Industrials," and, as on the occasion of the outbreak of the war, those responsible for the conduct of our stock exchanges took drastic measures to meet the then abnormal situation, and did so successfully, it is equally incumbent, if not more so that they now tackle the new situation and get it on a sane basis before it gets altogether out of hand and culminates in a business dislocation and demoralization from which it may take well on to a decade to bring back again to normal.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Toronto, Ont., Aug. 10, 1915.—There is little change to note in the industrial situation, conditions being much the same as during the last few weeks. Compared with conditions prevailing one year ago, the business outlook is favorable, and the steady improvement in trade is distinctly encouraging. Perhaps the most interesting feature is the improvement in the steel trade. Twelve months ago, conditions in the steel trade were very quiet and production had fallen off considerably. Now the mills are very active, and working almost to capacity. Production is practically all on account of the war. The crop reports generally are very favorable, and if the yield is as good as is anticipated, it will be of the greatest benefit to the country.

The trade returns for the Dominion for the last fiscal year recently published by the Department of Trade and Commerce contain some interesting figures. The imports of merchandise fell off by nearly 163 million dollars, as compared with 1914, while the exports showed an increase of a little more than four millions. The encouraging feature, however, is the fact that for the first time in many years the balance of trade in regard to exports and imports is in Canada's favor. This condition is, of course, entirely as a result of the war. The increase in exports of manufactured goods being one of the principal reasons for the favorable trade balance.

Steel Market.

The outlook in the steel trade continues to improve, which is due almost entirely to war business. Canadian mills are operating almost to capacity, and, in addition to the output of forgings and bars for shells, are producing other steel products, both finished and semi-finished.

It is reported that negotiations are pending between the Dominion Steel Corporation and the French Government for a large order of finished shells. It is understood that, while nothing has been definitely settled, a contract will be signed at an early date. If this business is closed the outlook in the shell industry will improve considerably, as it may lead to other orders for shells being placed here in addition to those being handled by the Shell Committee. It is rumored that the Russian Government has awarded another large contract for shells to the Canadian Car and Foundry Co. In any case it is extremely probable that it will be distributed among the same concerns in the States as the previous contract, and so will not be of any particular interest to manufacturers on this side of the line.

Prices on bars, plates, and small shapes are holding very firm, and higher prices for Pittsburgh products may be expected any time. Boiler tubes have advanced approximately $1 per 100 feet. Wrought iron pipe is very firm and an advance is expected in the near future. Galvanized sheets are easier to obtain, and spelter has declined somewhat. Some makers are still out of the market, and are only filling up old contracts. Prices of galvanized sheets are unchanged but have an easier tendency. The black sheet market is steadily gaining strength and quotations are firm with an upward tendency.

The high-speed tool steel situation is acute, and fears are expressed that the shortage will be very serious, if it has not already become so.

The conditions in the steel trade in the States continue to improve, and big business is being done in rounds for shells. Mills are so well supplied with orders for bars that they are conservative about taking on any more tonnage, although large orders are offering from foreign countries. The market is well established at $1.30, Pittsburgh, and it is expected that $1.35 will soon prevail.

OUR EMPIRE COHESION.

It needed this one supreme struggle to teach the world that when an enemy grappled with the British Empire, or part of the Empire, he grappled with the whole. The British Empire is stronger to-day than ever before. It will signalize to neutrals that it is more than a name; it will demonstrate that the one great unity is to be reckoned with as a whole, and not in sections. The Empire will be a power for peace that never existed before, and go far to solve the international relations of the world.

Pig Iron.

Furnaces connected with steel plants continue active, but the demand for foundry iron is light. The pig iron situation is improving in the States, and prices have a higher tendency.

Scrap Metals.

The market for heavy melting steel is active, and quotations firmer. Prices of copper and brass scrap are holding firm on good demand. Scrap lead is quiet, and prices have a weaker tendency. Zinc is quiet, and unchanged.

Machine Tools.

There is no change in the machine tool situation, and business is quieter after the recent spell of great activity. Inquiries are being sent out by firms contemplating making shells, but few orders have been placed except by those firms already engaged in making shells who are adding to their equipment. Makers of machine tools are very busy, and deliveries are still very backward. Dealers are not idle, however, by any means, as they fully expect increased activity later, and are making preparations to meet the demand as far as possible.

Supplies.

Business continues brisk in machine shop supplies. Prices are holding firm, and there are few changes of importance to note. Transmission rope is now being quoted at 20c per pound. The linseed oil market is unsettled, but prices are unchanged. An advance in the price of white waste will probably be announced very shortly.

Metals.

Continued weakness characterizes the metal markets. There has been no sign of a recovery during the week, and the weakness has been further intensified in the London market by the depression following the fall of Warsaw. While this loss indicates that the war will be prolonged and therefore increases demand for munitions and their many dequirements, yet for the time being these facts have been offset by the psychological aspect of the situation. The metals principally affected are tin, copper, spelter and lead, which have all declined in London, and also locally, with the single exception of copper, which, although dull, is unchanged. The antimony spot market is easier, but quotations are unchanged. The volume of business continues good, and compares very favorably with conditions prevailing twelve months ago, altogether apart from the increase in the demand for metals for munitions.

Tin.—The market in London is depressed and has declined again. Conditions in the States are good, but the New York market has been affected in sympathy with London. There is some scarcity of spot tin, and if there were a better tone in the market, a recovery might be expected. Tin has declined 1c, and is quoted locally at 41c per pound.

Copper.—The depression caused by the fall of Warsaw has unsettled the market, but quotations have been maintained. The prospect of a war of longer duration improves the position of cop-

per owing to the consequent larger demand for this metal. The market is dull and prices are unchanged at 21c per pound.

Spelter.—The market is weak, and lower with little buying. There is an entire absence of inquiry, and efforts to draw bids from buyers have met with little success. The scarcity of spot spelter has been largely overcome by the output of the smelters. Export orders have dropped off, and although these have been large over recent months, the shipments represent orders placed some time ago. Spelter has declined 2c and quotations are nominal at 23c per pound.

Lead.—There is practically no demand for lead. and the market is weak. It is extremely probable that the "Trust" will have to reduce their prices. Local prices have declined ¼c. and quotations are nominal at 7c per pound.

Antimony.—The spot market is easier, but there is a good inquiry for extended futures. Supplies of antimony are easier to obtain, but quotations are unchanged. and nominal at 40c per pound.

Aluminum.—There is no improvement in the situation as regards scarcity of aluminum. The market is firm and quotations nominal at 40c per pound.

St. John, N.B., August 7.—A practical suggestion for the speeding up of munitions supplies in Canada, at least so far as St. John is concerned, was heard by D. A. Thomas, former Welsh M.P., now touring Canada as special representative for Lloyd George, when he visited this city yesterday. Should the suggestion be adopted, it would have a far-reaching effect upon the city in the way of employment, besides contributing to the increased output of supplies of war.

In his inspection of the lately installed plant in the local Exhibition Buildings, Mr. Thomas was told by George McAvity, of T. McAvity & Sons, Ltd., that his firm intended to treble its output of shells and its proposed plant if sufficient orders were received. Beyond that, Mr. McAvity offered to the War Office the advantages of the whole expenditure to date on the plan and foundations of the site that T. McAvity & Sons, Ltd.. have acquired in Marsh Road, and of the firm's whole technical experience, if they wanted to erect a special factory for munitions. The offer was unconditional, except that the buildings and site should revert to the firm at the close of the war.

Some idea of the vastness of the offer may be gleaned from the fact that already upwards of $10,000 has been spent in preliminary work by the firm for iron and brass foundry purposes. Mr. McAvity particularly impressed upon the visitor the advantages in the way of shipping from an ice-free port, open all the year round, and said that if agreed upon, the new works could be in operation by next December, a matter of only a few months. The offer was heard with attentive interest by Mr. Thomas, who will report upon it.

Mr. Thomas while in St. John visited the various factories and foundries where war supplies are being manufactured, including those of T. McAvity & Sons, James Fleming, the Wilson Box Factory, and others. He did the same in Moncton, New Glasgow, Halifax and other centres in the Maritime Provinces. Speaking of Canada's share in manufacture of materials, he said that the progress made had been most remarkable. The only plant of its kind in Canada, a year ago, had been the small arsenal at Ottawa, employing about three hundred men. To-day more than one hundred towns, villages and cities through the Dominion were engaged in making supplies for war purposes. In view of the tremendous sacrifice Canada was making, he said, the British Government felt she should have all the war orders possible, especially since she had shown herself well able to meet them.

A New Elevator.

General Manager Gutelius, of the Government Railways, was in St. John this week, and was interviewed by a delegation from the Board of Trade. He assured them of pending improvements at this port as soon as finances were bettered, and of particular interest to St. John and Canada as a whole, he made the statement that a new elevator was to be erected here, not far from the Atlantic Sugar Refinery in Lower Cove. The new facilities would include also two piers 750 feet long. The elevator would replace that which was destroyed by fire last summer, and which would not be rebuilt on the old site because of other plans being had for work there.

Patriotic Endeavor.

The officials and employes of Rhodes, Curry Co., of Amherst, with their branches at Halifax, New Glasgow, and St. John, have contributed $1,000 to a fund for the purchase of a machine gun for the Militia Department at Ottawa. The certified check for the amount has been forwarded.

For the collection of a million-dollar fund for the care of wounded Canadian soldiers a practical suggestion has been made by W. E. Roop, foreman in the woodworking department of T. S. Sims & Co., brush manufacturers, St. John. He has put forth the suggestion that every working man in Canada give one day's pay to the fund, and thinks that in this way enough could be raised for the purpose.

Contracts Let.

A. R. C. Clark & Son, of St. John, have been awarded the contract for the installation of water and sewerage in Bathurst, N.B. The contract covers about $131,000, including the construction of a dam and pumping station, and about seven miles of water and sewage mains. A large stand pipe with a 405,000 gallon capacity is to be erected also.

E. W. Green has been awarded the contract for the erection of a new steel and concrete garage in Carleton Street, St. John. The site is 120 feet by 87, and it is reported that the purpose is to establish a line of jitneys here.

The contract for a new sewer in Lancaster has been given to Messrs. Kane & Ring. It represents an expenditure of about $10,000.

W. J. Hunter, of Sussex, has been awarded the contract for the erection of a large dam at Campbellton for the Shives Lumber Co. It will be about 175 feet long and 32 feet high.

CANADA'S TRADE POSITION.

THE trade returns of the Dominion for the last fiscal year, just published, reflect the general trade restriction both before and during the war up to March 31 last. As compared with the preceding year, there was a net decrease of about 158 millions in the exports and imports of merchandise. Imports of merchandise fell off by nearly 163 million dollars as compared with 1914, while exports of merchandise showed an increase of a little more than four millions.

It is encouraging to note, however, that for the first time in many years the balance of trade for the year in regard to imports and exports of merchandise is in Canada's favor, the total imports being $455,471,471, while exports are valued at $461,442,509.

The movement of coin and bullion, which was abnormal following the outbreak of the war, of course swells the total figures very considerably. The imports of coin and bullion during the last fiscal year amounted to no less than $131,992,992, as compared with $15,236,305 for the preceding year.

British Imports.

Canada's imports from the British Empire for the year totalled $116,272,787, a decrease of nearly forty millions as compared with the preceding year. Imports from Great Britain, which totalled $90,085,840, fell off by nearly forty-two millions. Imports from the British West Indies, however, increased by nearly two millions. Imports of merchandise from the United States last year totalled $296,632,506, a decrease of nearly a hundred millions.

Exports to Britain.

Canada's exports to British countries during the year totalled $237,558,704, a decrease of nearly ten millions, nearly all of which was in exports to the United Kingdom. As compared with this, Canada increased her sales of Canadian produce to the United States by some ten millions, the total for the year being $173,320,798. During the year Canada bought from the United States 123 million dollars' worth of goods more than she sold to the United States. In the case of Great Britain, the Dominion sold 121 million dollars' worth of goods more than she bought.

The increase in exports of merchandise during the year was due solely to the increased transportation through Canada of foreign produce, which was greater by some twenty-eight millions than in the previous year, and was made up principally of horses, oats and wheat bought from the United States for war purposes and shipped through Canadian ports.

Canadian Produce Exports.

The exports of Canadian produce show a decrease of $22,169,603. Exports of the mine decreased from $52,039,054 in 1914 to $51,740,989 for 1915; the fisheries from $20,623,560 to $19,687,068; agricultural products from $198,220,029 to $134,746,050.

On the other hand, exports of animal produce increased from $53,349,119 to $74,390,743, and of manufactures from $57,443,452 to $85,539,501. The increase in the exports of animal produce reflects, of course, the large sales to the United States of beef cattle following the taking down by the United States of the tariff barriers. The increase in the exports of manufactures is largely due to Canada's sales of war munitions to the allies.

Foreign Trade.

The effects of the war are seen in the figures of the trade with France and Germany. Imports from France last year totalled $8,449,186, as compared with $14,276,378. Exports to France totalled $14,595,705, as compared with $3,810,562 for the preceding fiscal year. From Germany Canada bought during the twelve months goods to the value of $4,314,805, as compared with $14,586,223 for the preceding year. To Germany Canada sold last year goods to the value of $2,162,010, as compared with $4,423,736 in 1913-14. The total trade of Canada with Germany in 1913-14 amounted to $19,019,969. In 1914-15 it amounted to $7,248,996. This year it will be nil.

The Quebec Streams Commission are having a large dam built above the La Loutre rapids by the St. Maurice Construction Co. The dam will cost $1,425,000, and will probably be completed in 1918. Fraser, Brace & Co., of Montreal, will undertake the greater part of the work.

Principles of Laying—Off Cylindrical Intersections---III.

By J. W. Ross

The more or less special nature of the work involved in the making of sheet metal piping has caused many manufacturers to avoid this class of work, with the result that when a job has to be handled, there is frequently considerable unnecessary loss incurred through errors in laying off material. The examples treated by the writer of this article should form a valuable reference to many manufacturers on ordinary as well as special occasions.

TEE WITH INCLINED INTERSECTION.

THE perspective cut, Fig. 23, and the side and end elevation, Figs. 24 and 25, show a pipe intersecting a larger pipe at an angle of 60 degrees.

Construction.

With centre O and radius equal to 1 inch, describe the circle P Q^1 1^2 Q^1 Fig. 24. This representing the end view of a horizontal cylinder of 2 inches in diameter. Draw the centre line P, O, 7 at right angles to the horizontal line Q^1 O Q^1. Continue the centre line Q^1 O Q^1 Fig. 24 over to Q Q, Fig. 25. Make this equal to 2¾ inches. At an angle of 60 degrees to Q R Q draw the line R 4. Project the points 1^2 and P, Fig. 24 respectively to the line C D and A B drawn parallel to Q R Q. Draw A Q C and B Q D at right angles to Q R Q. Measure L 4^1 equal to 1¼ inches. Draw 1^1 4^1 7^1 right angles to R 4^1. Make 4^1 the centre of the diameter 1^1 4^1 7^1 which is equal to 1¼. Parallel with R 4^1 draw the lines 7^1 7^2 and 1^1 1^2 to their intersection of the line C D. With centre X describe the circle 1, 4, 7, 10, with diameter equal to the neutral diameter of the inclined pipe. Divide this neutral circumference into 12 equal parts. Project these points—parallel with R 4—through the line C D. In a suitable position on the centre line P 7, draw the neutral circumference with the centre X, Fig. 24. Divide this into the same number of equal spaces as was done in Fig. 25. Parallel to the centre line project all these points down to the intersection of the cylinder Q^1 1^2 Q^1 P. Number accordingly where these points intersect the cylinder Fig. 24, project over by parallel lines to the intersection of similarly numbered inclined lines in Fig. 25, locating the points 2^2, 12^2, 3^2, 4^2, etc. Fig. 25. A fair curve drawn through these points locates the mitre line, and the flange line for light riveted pipe.

Development.

Measure off 1^1 7^1 1^1, Fig. 26 equal to the length of the circumference of the circle 1, 4, 7, 10 in either Figs. 24 or 25. Divide this line into 12 equal spaces. Draw vertical lines through these points at right angles to the line 1^1 7^1 1^1, Fig. 26. Number these points in consecutive order and in relation to the position of the longitudinal seam. Evidently 1^1 1^1, Fig. 25 will be the most suitable position for this seam as regards the driving of the rivets.

Take the distance 1^1 to 1^2, Fig. 25 and transfer this over to Fig. 26. Also take the distances 2^1 2^2, 3^1 3^2 4^1 4^2 etc. Fig. 25 and transfer these over to their correct position in Fig. 26. Through these located points draw the mitre line. Add on a suitable amount for lap and draw in the rivet lines.

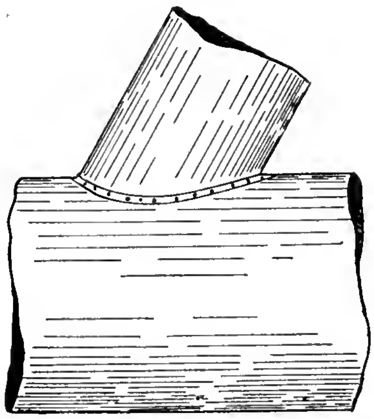

FIG. 23.

In the preceding problems the measurements of the elements, for transferring to the templet, may be taken from either the side or end elevations. Take for example Figs. 2 and 3. The measurement of the element 1^1, 1^2 Fig. 2 is equal to the measurement 1^1 1^2 Fig. 3. And 7^1 7^2 6^1 6^2 5^1 5^2 etc, Fig. 2 are all equal respectively to 7^1 7^2 6^1 6^2 5^1 5^2 etc. Fig. 3. In Figs. 24 and 25 this is not the case. The reason why will be briefly explained without going too deeply into the principles of projection. In both views Figs. 2 and 3, the centre line of the vertical cylinder intersects at right angles to the centre line of the horizontal cylinder. All lines parallel to the centre line in one view to that of the other, will show the true lengths of the lines. This condition meets the case of Figs. 2 and 3 as all the vertical lines in Fig. 2 are shown vertical in Fig. 3. Therefore the true length of similarly numbered lines are equal in each view. The true length of a horizontal line is shown by a straight line in one view and by a point in another. So in the case just stated it does not matter which view these measurements are taken from, providing they meet the conditions which were stated. In Fig. 24 the elements—1^1 1^2 2^1 2^2, etc.—are parallel with the centre line 7 P, also the elements—1^1 1^2 2^1 2^2 etc.—Fig. 3 are parallel with the centre line 4 R. But all the elements of one view are not parallel with all the elements of the other view. Therefore, the true length is not shown in both views. In Fig. 24 the centre line is shown at right angles to the horizontal line. But in Fig. 25 the centre line is shown at an angle of 60 degrees to the horizontal line. Therefore the elements will be foreshortened in Fig. 24 and their true lengths shown in Fig. 25. As will be observed, the true length of elements were transferred from Fig. 25 to the templet in Fig. 26. By the way if the vertical centre line in Fig. 24 had also been inclined to the horizontal line, then the elements in both views would have been foreshortened. The true length would then have to be found by construction. This construction method is termed triangulation, which will be explained in a forthcoming issue.

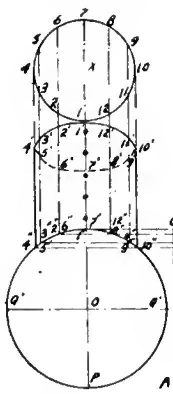

FIG. 24.

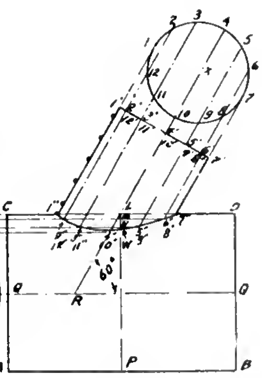

FIG. 25.

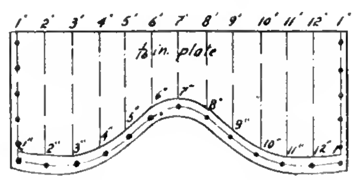

FIG. 26.

Development of the Intersected Pipe.

The diameter of the circumference P Q^1 1^2 Q^1 equals 2 inches. The stretchout will equal 2 × 3.14 which is 6.28 inches,

or slightly over 6¼ inches. Measure off B D B Fig. 27 equal to this distance, Bisect at D and raise the perpendicular D C. Measure along the curve the distances 1^2 2^2, 2^2 3^2, 3^2 4^2 etc. Fig. 24, and transfer over to 1^2 2^2, 2^2 3^2, 3^2 4^2 etc. Fig. 27. From these points draw lines parallel to the centre line C D which is also denoted by 1^2 7^2. Bisect A B at P Fig. 27. Draw the centre line P P. Where P P intersects the elements, letter as shown in Fig. 27.

Bisect A B Fig. 25 at P. Erect the perpendicular P L. Locate the points M N W at the intersection of this line

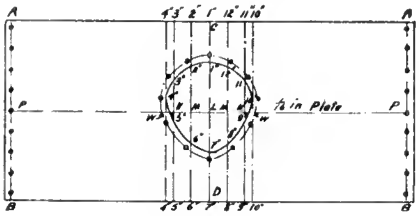

FIG. 27.

with the horizontal projection lines. Fig. 25. Set the dividers to the distance L 1^2 Fig. 25. Transfer to L 1^0 Fig. 27. Again set the dividers to L 7^2 Fig. 25. Transfer this distance to L 7^0 Fig. 27. Similarly take the distances M 6^2, M 8^2, M 2^2, M 12^2, N 3^2, N 11^1, N 5^2 N 9^2, W 4^2 W 10^2, and transfer to their allocated lines in Fig. 27. Draw a fair curve through these points to define the opening of the cylinder.

Draw in the rivet line and space off the rivet centres at the proper distance from the edge of the opening. Divide A B into a suitable number of rivet centre spaces. Transfer these centres to its connecting seam A B. Add the laps to complete the templet.

BLANKING AND FORMING DIES FOR PATENT HOSE HOLDER.

By Spring Craig.

In figure No. 1, at A, is shown a patent hose holder of cast brass to be used for holding hose when sprinkling lawn. In B, drawing 1, another view of K is shown. This part is to be placed in the ground and the swivel or knuckle joint is to allow the nozzle or sprinkler to be turned in any direction and clamped by the wing nut shown. The wing nut clamps the two parts h on the two pieces gg, thereby clamping these pieces firmly on the hose f. A pin through the end keeps the two pieces h from swivelling. At J, the two ends of gg are formed into half spheres, with a projecting ring cast on one and a recess in the other. This is to keep them in line when changing the hose from one position to another. As these had to be sold at a low price, it was not feasible to make them of brass, for the weight of brass in each one, along with the time taken to mould them, would be considerable. They could have been made by die-casting methods with the proper mixture, but being a new article, and with the extent of the demand unknown, it did not justify the cost of die-casting dies to commence with. The final conclusion was to make them of sheet metal in blanking and forming dies. The next question to decide was the weight and kind of material.

Selecting Suitable Stock.

Experiments were tried with different thicknesses of soft sheet steel to arrive at an idea of how light they could be made and yet strong enough to serve the purpose. The weakest point would be at the wing nut on account of the clamping and the hole for the wing nut weakening the stock. It was found that No. 15 B. & S. gauge, which equals .057 of an inch, was about the lightest that could be used. It does not take long for the cost of a slight difference in the thickness or weight of stock, considering the scrap along with the amount actually used to amount to a considerable sum. Sometimes through modifying or slightly changing the design of the article the price of the dies and more can be saved, providing any considerable quantity are required. Often it is possible to arrange the lay-out of piercing and blanking dies and simple blanking dies, so that by

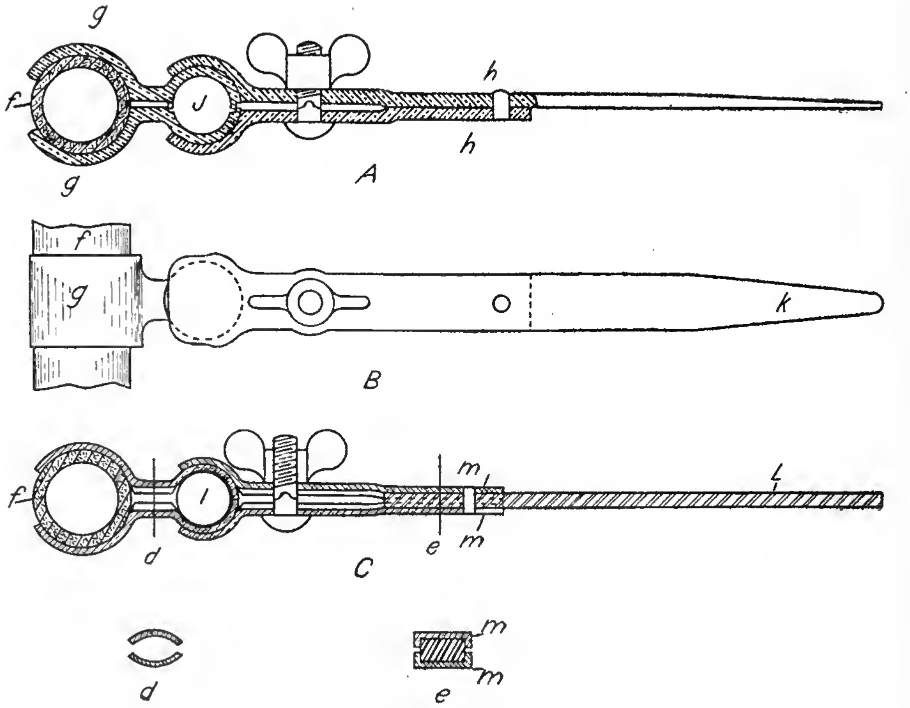

FIG. 1. PATENT HOSE HOLDER.

blanking out every other one, then reversing the stock and running the stock through the dies again, the amount of scrap can be cut down to the lowest possible amount. One difficulty, which eventually proved to be much simpler than appeared at first, and which held up proceedings for some time, was how to keep the two pieces gg in line without making an extra set of dies. As a certain amount was stated as being the probable cost of the dies, these extra dies would not be possible.

It was suggested that a marble be placed between as at 1 in C, figure 1. This served the purpose admirably of keeping them in line. Otherwise the sheet metal hose holder was designed as shown at C, figure 1, longitudinal section, d and e cross sections. The neck was curved, as shown in cross section at d, for strength. For the long tapered part at L, a piece of 5/16 x ½-in. stock was used, tapered at one end, and held between the two pieces mm by a rivet.

Determining Proper Size of Blank.

The size and shape of the blank used in the forming dies has generally to be obtained by experiment, especially if the design is in any way complicated. The forming dies are always made first, and the experimental work is done with the dies soft in order to be able to change them if necessary. First a blank is laid out by figuring and judgment, and two blanks are cut out. One is formed up in the forming dies, and the result will show where the remaining blank has to be changed. Before forming this second blank, a duplicate of it should be made, and if a third blank has to be used for trial, a fourth blank should be made, which would be an exact copy of blank number three before forming. When one is at last formed up satisfactorily, there is a correct template left to lay-out the blanking die by. At A B C D, figure 3, are different views of the forming dies for part m in C, figure 1.

F E are the punches held in a steel pad. B is the forming die; a and b are pins actuated by spring and washer shown to push out the formed piece. On top of the die is a locating piece I machined

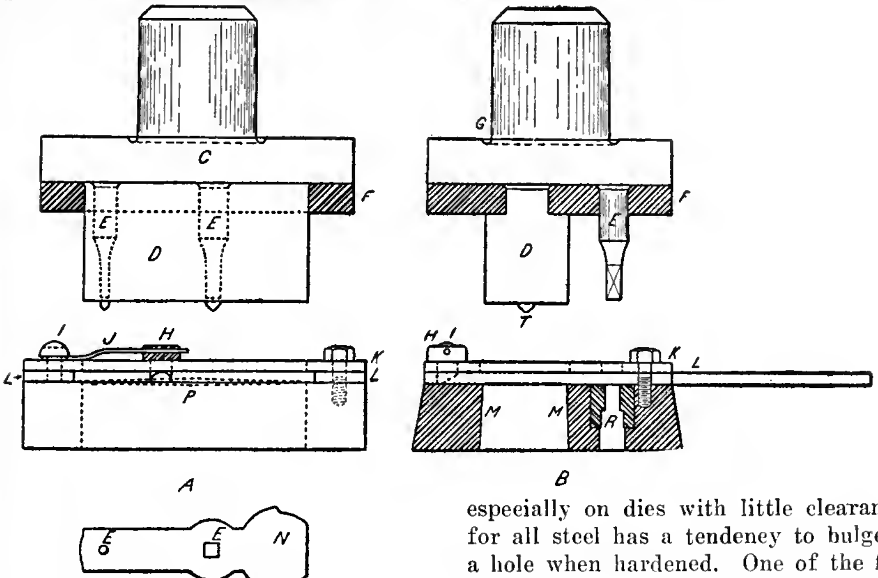

FIG. 2. PIERCING AND BLANKING DIE.

out to fit the blank at different points to properly locate it. The bevel at J J is usually made from 5 degrees to 15 degrees. Common practice is 10 degrees.

The forming die for piece g, figure 1, is constructed on the same principle, but to suit the different shape. The radius of the corner should never be less than the thickness of the stock, and should be highly polished on those parts over which the stock has to bend when being forced into the die by the forming punch. If the sides of the formed article are cut and scratched, the round or radius is not large enough. After the forming die is finished, the next step is the blanking die. On figure 2 at A and B is the blanking die for piece N, that is a duplicate of the one that formed up satisfactorily, as shown at m in figure 1.

A Gang Die.

This type is usually known as a gang die because, while punch D is blanking the article, the small punches E E are piercing the stock for the next blank, so that each time the stock is fed ahead, or at each stroke of the press, there is one piece pierced and one piece blanked. To proceed in the best manner is to work out the blanking die first and lay-out the holes for the piercing dies from it. When it is desired to get the greatest amount of work out of a die, the clearance or taper from the bottom to the top or cutting edge is only about four thousandths on a side. The writer has seen dies that were an inch thick when new used, until there was only three-sixteenths of them left. When there is only a limited number of blanks required, one-half to one degree clearance can be given. At M M on cross section B, in figure 2, if the clearance is made a little hollow, a whole lot of trouble and annoyance will be saved, especially on dies with little clearance; for all steel has a tendency to bulge in a hole when hardened. One of the first blanking dies the writer made burst in use through punchings clogging and jamming. Later, half a day or more had to be spent oilstoning clearance after hardening.

Bushings are used for the piercing dies, providing that the die will be used extensively, as they get dull quicker than the blanking die. At L the back guide for the stock extends for three or four inches to facilitate keeping the stock in line. K is the stripper fastened to the die by dowels, which are made of stubs steel, which pass through the guides L, and is held down by hexagon screws.

The stop H, under which the stock is pushed and pulled back against, is an improvement on the style of stop which

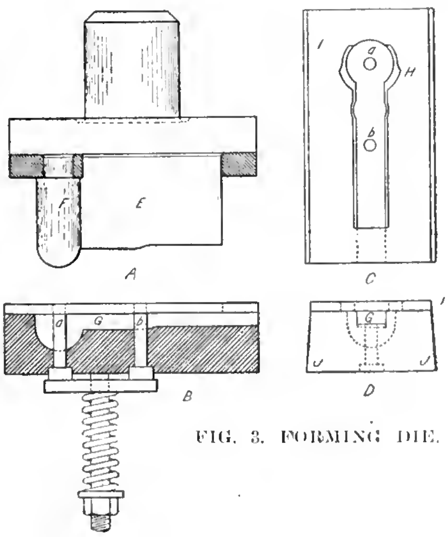

FIG. 3. FORMING DIE.

is fixed in the die, and over which the stock has to be lifted.

The spring J, made preferably of piano wire, keeps a downward pressure on the stop.

Hardening the Die.

In hardening the die, if the heating is done slowly, especially at the start, and evenly to the proper hardening heat, then dipped edgewise perfectly square, as shown in figure 5, and moved slowly back and forward in the water until it is cool enough to bear the hand before withdrawing, little trouble will be experienced with reliable makes of tool steel or cast steel. The die then should be immediately polished and drawn down to the desired temper. All screw and dowel holes should be plugged with fire clay or asbestos. The idea in moving the die back and forward is to allow the water to pass through the die, thereby eliminating the possibility of steam and air pockets forming, which will cause part of the cutting edge to be soft. In dipping, the heavy side is entered first, because it takes longer to cool than the light side; also being heavier and stronger when cooled first, the light side being still warm, has a chance to conform to shrinkage, etc., set up by the

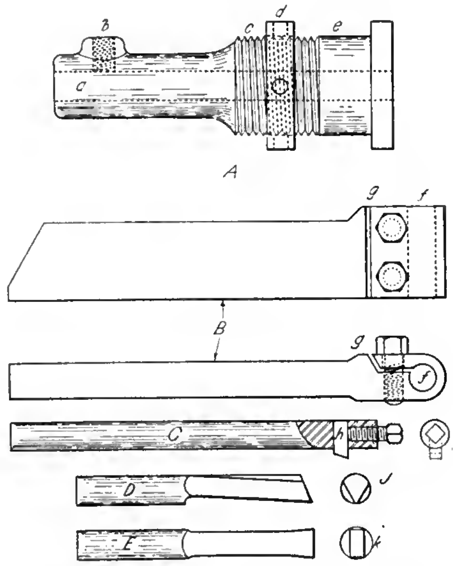

FIG. 4. SPECIAL SHAPER TOOLS FOR DIE MAKER.

heavy side. If the order were reversed and the light side dipped first, what happens is that the light side sets—then the stronger and heavier side alters, shrinks and warps—there are strains set up in the die; and, as the lighter side is set, it cannot give, and bearing the weakest part, it is where the fracture occurs. Soap, oil, etc., should not be in the water, as they will cause uneven hardness, a little potash bites or cools quicker. For dies on tin work, salt in the hardening water causes the tin work formed up in the dies to rust; and if the dies are stored in any kind of a damp place the dies will rust.

Fitting the Punches.

In most up-to-date shops the punches are held in a steel pad, as shown. The steel pad is doweled to the cast iron

punch holder and secured by flat-head screws. The large punch is always fitted first. The piercing punches should be a little more than the thickness of the stock, shorter than the blanking punch, for the reason that the blanking punch draws the stock and also binds it some, especially when the dies have shear. By shear is meant that the top or cutting face instead of being planed flat is planed either concave or convex, as shown by dotted lines, as at P in A, figure 2; this shear makes an easier working die. In spacing the blanks, there should not be less than the thickness of the stock in width around the blanking punch to do away with the tendency of the scrap turning edgewise, forcing the punch to one side, causing injury to the die.

The punch is only hardened about half-way up, leaving the top end soft, which allows of its being riveted into the pad. When dipping in the water for hardening, it is advisable to keep moving the punch up and down. If this is not done, and the punch held stationary, there is likely to be a water crack at the point reached by the top of the water.

The punch should always be drawn or tempered softer than the die. It is not known generally to mechanics that it is not the actual cutting of stock by the die that dulls it so much as the punch, owing to the press-ways being loose or worn, or through slight differences in thickness or hardness of stock, causing the punch to deflect from one side to the other, and thereby injuring the die. In sub-press dies, where punch and die are held rigidly in line and dies prevented absolutely from creeping by hardened and ground pins fastened in the bolster and passing through hardened bushings in the punch holder, the dies will do a great deal more work between grindings. There was .0015 clearance all around between the punch and die. A certain amount of clearance is always allowed between the punch and die for piercing and blanking. One-thousandth clearance for stock, one-sixty-fourth thick up to ten-thousandths for stock one-quarter of an inch thick.

Special Tools.

In figure 4, are samples of diemakers' tools for the shaper to facilitate this work, and which can also be used to advantage on other jobs. At A, figure 4, is a tool holder that is used in the clapper block in place of the regular shaper tool holder. The cutting tool is held in (a) by a set screw in b. At d is a collar threaded on to the body e, which locks the tool holder securely in place when tightened. The clapper block is held from moving by a set screw in the side of the clapper box. A hole has to be drilled and tapped in the clapper box for this set screw, as new shapers never have one, but it does not in anyway affect the working of the shaper when not in use for this special purpose.

At B is another style of holder that can be used in the regular tool holder. Cutter bar C, containing cutter h, can be used for die work, but is especially handy in a small shop for cutting keyways. At D and E and J and K are styles of tools most commonly used on dies, and can be held in either tool holder A or B. Tool holder B is made of machine steel, case-hardened around f in order that when the binding screws are released it will readily spring open, allowing the operator to turn the tools any desired angle. These clamping screws do not need to be tightened to the limit, for if by an accident the tool is fed in too deep or is caught, it slips back through and does no harm. Stubs steel is used, and by making suitable split bushings, any desired size of tool can be used.

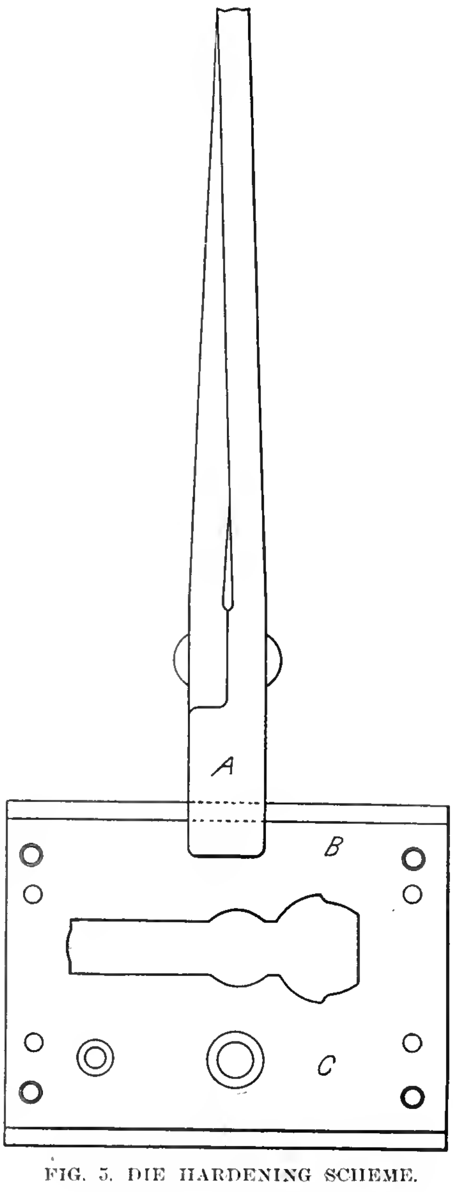

FIG. 5. DIE HARDENING SCHEME.

METAL SHIPMENTS.

SHIPMENTS of brass bars, plates and sheets from the United States in May were more than twelve times those of the preceding May, while for the eleven months ended May they were seven times as great as in the previous corresponding period. This is another illustration of the reversals that have taken place in those metals that are used for ammunition making. The following table gives the U. S. exports of brass, in pounds:

	—May— 1915.	1914.
Scrap, old	1,205,848	1,730,563
Bars, plates, etc..	5,941,185	474,411
	—11 mos. ended May— 1915.	1914.
Scrap, old	15,174,777	22,994,683
Bars, plates, etc..	35,322,141	5,078,608

A metal which has been revolutionized, as far as exports are concerned, is zinc. Exports of U. S. zinc in May, in the shape of pigs, bars, etc., were 15,270,854 ponnds, to which should be added 2,207,903 pounds of zinc from foreign ores smelted in that country, against a total of 214,201 pounds shipped in May, 1914. For the eleven months ended last May, exports of zinc, foreign and domestic, totaled 257,408,584 pounds compared with 3,737,647 for the corresponding period of the previous year.

PERFECTING INDUSTRIAL MATERIALS.

AT the present stage of development, the efficiency not only of workers but of what they work with is a matter of great concern to the world's engineers. The thoughts and efforts of thousands of men are being directed simply to removing the dangers of unsound structural materials. Failure may come even without the stresses of actual service, the problems of ensuring reliability being many and difficult. Condenser tubes of brass, for instance, have been observed to crack simply when stored up in the yard, and some articles of this metal become so altered under atmospheric influences as to crumble between the fingers. Serious internal strains also are developed by unfavorable conditions. A special study has been made of the faults arising from the cold-working of metals—cold-drawing, cold-rolling, cold-hammering, etc.—and it is found that these strains may closely approach the resisting power of the metal. Unforeseen failure may be caused by very slight external causes, such as scratching, unequal heating or cooling, or apparently insignificant corrosion.

NOTES ON BEARINGS.

By H. Womersley.

THE design of bearings of all kinds is a most important problem connected with machine construction. A journal should be designed of such a size and form that it will run cool, and with practically no wear. Heat and wear are the results of friction; therefore we must define friction. Friction is the force acting between two bodies at their surface of contact when being pressed together, and which operates to prevent their sliding upon each other.

Bearings operating under ordinary working conditions warm up until the heat radiated equals the heat generated. They will remain at that temperature, provided there is no change in lubrication, load or speed.

Suitable Oils Necessary.

The pressure which any bearing will stand without seizing depends largely on the temperature, velocity of rubbing, and quality and description of lubricant in use. The lower the temperature the greater the pressure, and the higher the velocity of rubbing the less the pressure. This is due to the fact that oils become thinner and more free flowing as higher temperatures are reached, and consequently more easily squeezed out of the bearing.

A very light oil is liable to be squeezed out at a pressure as low as 50 or 60 lbs. per square inch, whilst a heavy cylinder oil will possibly stand a pressure of 1,000 lbs. per sq. in. The advantage of selecting suitable oils is, therefore, apparent. When a load is unvarying in amount and direction, the oil film is easily broken, but in cases where the load is variable in amount and direction, as in railway car journals and crank pins, the oil film is much more durable.

It has been ascertained that the lubricant in railway car journals, where the force varies continually in amount and direction, will stand twice the amount of pressure of the steady fly wheel journal, and in a crank pin, where the load reverses every revolution, the film will withstand three times that of the steady fly wheel pressure.

A bearing may give poor satisfaction, because it is too long, as well as because it is too short. Almost every bearing is in the condition of a loaded beam, and, therefore, it has some deflection. We will take the case of an overhung crank pin, in order to examine the phenomena occurring in a bearing under these circumstances.

When the engine is first run, both the pin and bushing are truly round and cylindrical. As the pin deflects under the load, the pressure becomes greater on the side toward the crank web, breaking down the oil film at that point, and causing heat. After a while the bushing

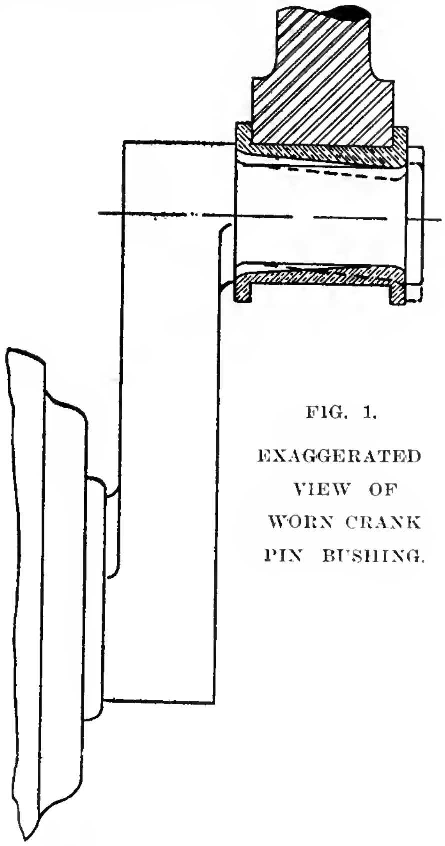

FIG. 1. EXAGGERATED VIEW OF WORN CRANK PIN BUSHING.

becomes worn to a slightly larger diameter at the side toward the crank, in the manner shown in Fig. 1. This is, of course, an exaggerated idea of the conditions of affairs in the crank pin bushing under load.

Requirements for Success.

For successful working, the bushing and pin must be accurately machined, and may, therefore, vary within narrow limits. The bushing must be a trifle larger than the pin. Should the pin be too large, the oil film will be too thin and easily ruptured. On the other hand, should the pin be too small the bearing surface becomes concentrated at a line, and the greater unit pressure at that part ruptures the film.

This is exactly what happens when the pin is too long. The bushing rapidly wears large at the inner end, and the pressure becomes concentrated along a line as a consequence. The lubricating film then breaks down, and the pin heats and scores. That there is always an element of doubt in regard to bearings is evidenced by the fact that our modern engine builders usually deliver an extra set of bearings with the engine, so that in the event of trouble a new set is at hand.

Workmanship Largely Responsible.

The workman plays a great part in the efficiency of a bearing. Investigation has shown the following to be the main reasons for hot bearings:—

1.—Shrinkage strains set up in the babbitt metal liner by the unequal distribution of the babbitt metal over the shell.

2.—A lack of contact between the babbitt metal lines and the cast iron shell.

3.—The lubricant becomes partially deflected into the wrong place.

4.—Oil grooves cut wrong, because instead of helping the lubricants, they generally drain the oil from where it is most needed. Proper lubrication of bearings involves careful consideration of the materials comprising the journal and its bearings.

Bearings in general use are mainly of cast iron steel, various alloys of bronze and babbitt. As lubricant material is intended to prevent contact between the metallic surfaces, it follows that the greater the pressure of the work per sq. in. of bearing surface, the greater the required viscosity.

Mineral oils semi-fluid at 68 degrees Fahr. may lose half their viscosity at 95 or 105 degrees and become quite mobile at between 122 and 140 degrees.

Heavy-bodied syrup-like liquids at low temperatures offer great resistance to fluidity and the displacement of their particles, and are most suited for slow speeds and heavy pressures.

For light-running shafts a mineral oil of suitable viscosity is desirable.

To sum up, the lubricant should possess a sufficient degree of viscosity, so that it is neither squeezed out between the moving surfaces nor wasted by the rapid motion of the running machinery. In other words, the oil should have just sufficient viscosity to keep the moving surfaces apart under the maximum pressure. It should be also free from grit and suspended matter.

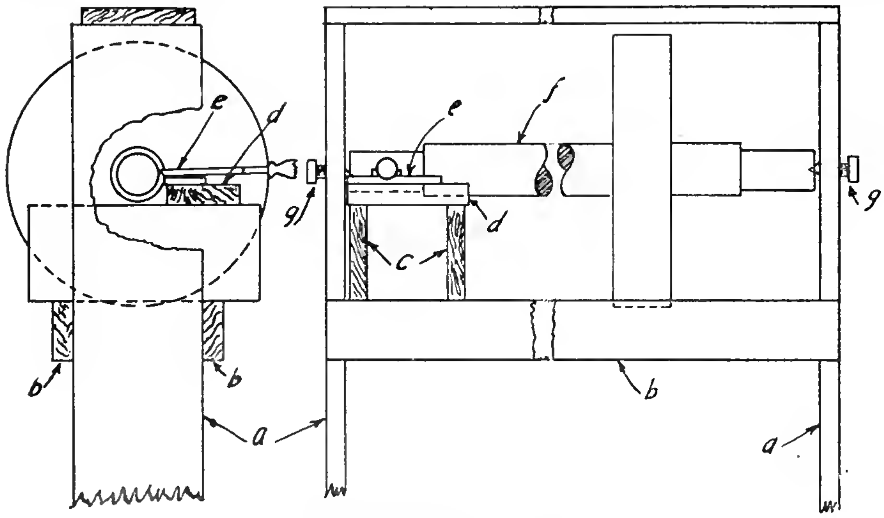
If these conditions are faithfully carried out, many troubles and much expense will be avoided.

A LUMBER LATHE.

By J. McCormack.

THE article entitled an "Ingenious Way Out of a Difficulty," which recently appeared in your columns, brings to mind a similar repair made some time ago in a shop unprovided with suitable equipment.

One of the journals of a six-foot shaft, 2 7-16 ins. in diameter, travelling at a speed of 1,550 r.p.m., had, by hard usage, overloading or lack of proper lubrication become badly worn, and after a time became quite troublesome. Rebabbitting had been tried with very poor results, owing to the scored condition of the shaft. Application of a pair of calipers revealed the fact that the journal was not parallel and also out of round from 1-64 to 1-32 of an inch, due, no doubt, to the uneven density of the metal.



LUMBER LATHE DETAILS.

There being no lathe within a distance of a number of miles and as the expense of transportation would have been considerable, the following "repair-on-the-spot" method was adopted with fairly satisfactory results.

The two planks (a) and (a) which comprise the "headstock" and "tailstock" of the "lathe" were held in a vertical position by the "bed" planks (b) and (b) at a distance slightly greater than the length of the arbor (f). The "saddle" planks (c) and (c) were placed crossways on the bed and supported the "compound rest" (d).

The "tool post" (e) consisted of a piece of flat steel secured to the plank (a), and the "centres" of the "lathe" were a couple of wood-screws (g) and (g).

The turning operation was performed by using an old file ground on the end in the shape of a flat scraper, being allowed to move freely upon the piece of flat steel. By careful handling of the scraper a fairly good job resulted. The arbor was revolved by belting the pulley to a line shaft. In the absence of a power shaft fairly good results might be obtained by revolving the pulley by hand.

When the arbor was replaced, rebabbitted and scraped, better results were obtained than had been the case since the first season of installation. Later a lubricating device was added, after which the bearings gave no further trouble.

TRIBUTE TO OUR FLEET.

THE Archbishop of York, at a Mansion House meeting at York recently, gave his impressions of a visit just paid to the Grand Fleet.

His Grace said: "I am still compelled to speak of that visit with very considerable reticence for obvious reasons, though I hope that the time may come when I may be able to give some record of it. I find it quite impossible to convey any impression of the scenes which I saw or the spirit which I felt, but it is sufficient for me to say that I realized as never before the debt which we here at home owe to these sleepless guards of our island shore. You will realize that these men have been out, not for three minths nor six months, but for twelve months; that during certainly five of these months they suffered hardships which it is difficult for me to describe, spending practically the whole of that time at high speed on wild seas unable to find any secure place of refuge or of protection.

Even now, though happily they are able from time to time to find places of rest, they are all of them living under war conditions, ready to steam out at short notice whenever the challenge comes, under ceaseless strain of manifold difficulties and dangers that we find it very difficult to understand, very near in some cases to their homes, and yet denied the chance even of short leave. There are thousands of men there who, during the whole of these twelve months, have never had a chance of even seeing their wives and children, yet I find there in every part of the fleet, from the Commander-in-Chief downwards, the same spirit of cheerfulness, of readiness, of determination.

It was to me a very great privilege to be allowed to bring to them a message which I hope was real and was sincere, that though our fleet is necessarily out of sight, it is never out of mind. My business was to tell these men that their country was standing by them and was grateful to them, but I am bound to say that having visited them I feel it is more incumbent upon me to bring some word to the people and to ask our fellow-countrymen at home, whether we really are standing by them, whether our sacrifices, our determination, and our unity are in any degree comparable to theirs. All I can say is that if the citizens here at home are filled with the same spirit of devotion, comradeship, and unity as fills our guardians of the fleet, then, humanly speaking, we need have little fear of the result."

EVERY MAN FOR HIMSELF.

THIS condition is the antithesis of co-operation and is present to an undesirable extent all around us. Some go so far that they follow this policy at the expense of others and associates. Others unconsciously follow such a policy to a lesser degree. Co-operation is necessary to secure any degree of efficiency and in the same organization one must, in a sense, make the other fellow's business one's own business also.

The man who neglects co-operation is destructive to organization. In his own eyes only his opinion holds good, he accepts the asistance of associates indifferently, finishes his job just as far as duty requires and passes it on to the next department and stops right there. Other fellows "go out of their way to do a favor." When they go to attend a poor light complaint, they fix the door bell which is out of order, and if, on the way out, the car runs off the track, they get out and help the crew apply the jacks.

These are extremes. Both fellows injure themselves, but the last man's attitude is to be preferred. A common-sense view and application is better. We should always be ready to assist each other in an open, broad-minded manner, not open to the criticism of an attempt to usurp another's duties or authority.

July Fire Loss.—July fire loss in Canada was only $773,269, the lowest by far of any July in several years. The economical and careful spirit engendered in the public mind by the war may have had something to do with the record. The total fire loss for the first half of the year amounts to $8,017,053, of which Ontario suffered $3,279,316.

CONTEMPORARY WAR ARTICLES

Embracing Information and Data Drawn from a Variety of Sources Relative to and Arising from the Prosecution of this Many-Sided European War

MODERN MUNITIONS OF WAR.

IN his second lecture on "Modern Munitions" at the Royal Society of Arts recently, Professor Vivian Lewes discussed shells and high explosives. Before coming to the actual subject matter of his discourse, however, he said there was one point he could not help mentioning. He realized that the Society of Arts was not the place for contentious matters; certainly it was not the right place to discuss political questions and political methods, but there was one factor he could not pass by, and which was that in the management and conduct of the war probably the most serious mistake that had been made had been to omit placing an embargo on cotton, which would prevent it getting into German hands. He had shown in his previous lecture that for every propellant made the world over cotton was an absolute necessity.

Cotton Importation Into Germany.

It was known for a fact that Germany had been collecting and storing cotton in enormous quantities before the war commenced; it was known as a fact that Germany expected to smash through everything and force a decision by last Christmas, and we know as a fact that the delay in doing so had upset to a very considerable extent her arrangements. Therefore, there was not the least doubt that, if cotton had been made contraband at the very commencement of the war, long before this Germany would have been feeling the pinch seriously. Inasmuch as, however, direct importation into Germany only had been stopped, it happened that we found for the first three months of this year the neutral countries such as Holland, Sweden, Denmark and Norway imported exactly six times as much cotton as they did for the first three months of last year.

Thus we had a very shrewd idea of where this surplus cotton went, and before it was too late he sincerely hoped that some diplomatic method might be found for getting out of this trouble. At the same time, it was all very well to say that so-and-so should be done. We knew perfectly well that we had diplomatists at work, in England especially, who could not be surpassed, and there were excellent reasons for what had been done, but we were now at a point when so many lives were depending upon this matter, and when it was an absolute necessity to stop the supply of cotton to Germany, that no diplomatic interference ought to be able to prevent an embargo of the strictest kind being put upon it.

High Explosive Shells.

Professor Lewes then proceeded with his lecture proper. He first described the ordinary shrapnel by the aid of a colored sectional drawing, and explained, as an instance, that a 6-in. shell with its 375 bullets would cover an area of 300 yards in diameter, and that this was the most effective form of shell for use against troops in the ordinary way. There was no question of any shortage of these. The shortage had been in high explosive shells, the need for which had only arisen with the present war. Such shells when they burst produced such an enormous concussion in the air that obstructions and impediments in the way of the troops were swept away. The effects were simply tremendous. By the mere impact of the wave they set up in the air men were killed at very considerable distances without being touched by any fragment of the shell.

High explosive shells of this character were used for siege work and for armour-piercing. In the latter connection a large amount of research had been carried out with the object, on the one hand, of increasing the strength of armour plate, and on the other, of producing a high explosive shell to penetrate that armour. The shell in that case was made, not of forged steel, as in the ordinary high explosive shell, but of nickel-chrome steel.

The lecturer then explained the phenomenon of the soft nose, which was so well illustrated by Sir Robert Hadfield in his lecture before the Institution of Mechanical Engineers last session. The remarkable effect of this soft nose was, he added, discovered, like so many other things, by accident. Whilst experiments were being carried on, a shell was fired at the back of a test piece of armour-plating, which was the soft side of the metal, and it was found that the shell went through and exploded after impact, whereas when the shell was fired against the front of the plate, which was the hardened and tempered side, it shattered and left an indentation of only a few inches in the plate. This led to the adoption of the soft nose, with the result that a shell could be made which would go through the toughest piece of armour plate that could be produced. Of shrapnel and the class of high explosive shell mentioned above there was no shortage whatever. It was only the high explosive shell for field purposes which had given trouble and in which there was a shortage.

Hand Grenades and Bombs.

Before dealing with the nature of the chemicals employed in the manufacture of high explosive shells, Professor Lewes described and exhibited the hand grenades and bombs which have become such a feature of the war. The service pattern rifle grenade is a small shrapnel shell, devised by Hale. Its casing is serrated, and it contains a cartridge of four ounces of trinitrotoluene, which is fired by a detonator. Attached is a vane for directing the flight and operating the detonating mechanism. The firing is effected in ordinary use of the rifle, except that the bullet of the cartridge is extracted and the end filled up with beeswax. The range of such grenades is about 350 yards, and a special sighting arrangement is fixed for use where the grenades have to be dropped upon the enemy and not fired in a straight direction over a short distance.

With the hand grenades the range is naturally considerably shorter, being about 45 or 50 yards, and in order to prevent premature bursting of the shell, arrangements are made for the firing action not to operate until after the grenade has travelled 15 yards. Another form of hand grenade exhibited had a larger number of serrations and exploded by percussion through striking an object.

Nature of High Explosives.

Attention was next directed to the nature of the high explosives actually used. It was demonstrated how all burning depends upon the oxygen in the air, but that this is such a slow process that an explosive mixture could not be made. By taking substances, however, in which it was possible to have oxygen in a compressed form and yet available for burning, a useful explosive could be obtained. Such substances were almost unlimited, and mention was made of chloride of potash and potassic nitrate, both of which contain about 600 times their volume of oxygen, the latter, of course, being used in the old gunpowder. A number of experiments was made to show varying degrees of rapidity of explosion.

Nitro-glycerine was next referred to as one of the very highest explosives, and an explanation was given of why the greatest effect of the explosion is in the downward direction. The lecturer then sketched the production of picric

acid from coal tar derivatives, and pointed out how in 1882 Sprengel, before the Chemical Society, demonstrated that picric acid by itself could be detonated and give a fine explosive result. Nothing more was heard of the matter for two or three years, when Turpin, a French student of explosives—a dentist at the time, by the way—took out a patent for using it as an explosive for filling shells, and it was introduced into the French service under the name of melinite.

Lyddite.

The accounts which reached Britain of the wonderful effects of this new explosive, that it would kill a man at 200 yards without touching him and knock down any fortification, created considerable alarm in the newspapers; but in a couple of weeks our Secret Service knew all about it, and experiments at Woolwich proved it to be an old friend, because several years before Sir Frederick Abel had introduced picric acid as powders. Experiments were then carried out by us at Lydd and a mercuric fulminate detonator used, with the result that this explosive was introduced into this country as lyddite.

It proved, however, a disappointing explosive. In the South African war it was found that on many occasions the explosion took the form of a semi-burning, and this was subsequently traced to the fact that we had not used sufficiently powerful detonators. Later on, the Japanese, in the Russo-Japanese war, used strong mercuric fulminate detonators and shells of the same explosive, which was called by the Japs Shimosi powder, did good work at the siege of Port Arthur. The Japs, however, took risks in doing so and paid the penalty in serious losses of men and material by premature explosions.

Trinitrotoluene.

All this time the Germans were watching with the greatest interest everything that was going on and noticed the weakness of lyddite and the Shimosi, which was that they formed certain compounds leading up to premature explosion. The Germans eventually hit upon trinitrotoluene, a product of the carbonization of coal. The present process of coal carbonization for the purposes of gas manufacture did not give a very large amount of toluene owing to the high temperature in order to give the best results from the gas point of view; but with a lower temperature the amount could be very considerably increased, and there was not the least doubt that if the war lasted very long and larger quantities of toluene were necessary in order to get high explosives, then a lowering of the temperature of coal carbonization in gas works would have to come about.

Toluene was also being made synthetically in considerable quantities by the action of heat and pressure upon other hydro-carbons, and both sources put together would undoubtedly give us very considerable quantities of toluene and as much as we should require for nitration purposes in the future. The lecturer showed various samples of T.N.T. and explained how it is copper-plated to prevent mechanical damage. He also dwelt upon the safety with which it can be handled, and emphasized that the tremendous effects produced follow detonation.

Ammonite.

A stronger explosive than T.N.T., however, was ammonite, which consisted of nitrate of ammonia mixed with 15 per cent. T.N.T., and which was invented in Austria. The advantage was the great economy in T.N.T., and for one branch of the British service we were now making considerable quantities of this explosive.

Still higher explosives, however, were being made, one of which was obtained by using benzol as a basis, and in this way the mining explosives of roburite and bellite were obtained.

Another new explosive about which a good deal more would be heard in future was tetranitro-anyline, which had the advantage over nitro-glycerine, that it was sufficiently inert to be safe in use; and finally there was an even more powerful explosive, viz., tetra-nitro-methyl-anyline, known as T.N.A. This latter had a tremendous concussive effect, and was the cause of men being found dead, but to all outward appearances uninjured. Many cases had occurred in which a displacement of the heart to the extent of nearly 2 in. had been found, and this had been caused simply by the concussive effect of T.N.A., and not by poisonous gases, as was often stated in the newspapers.

All this, concluded Professor Lewes, was part of the horror of war. The mischief from hell's kitchen—poison gases—with which the Germans had disgraced themselves, he would deal with in his next lecture.

SAFETY FEATURE OF HIGH EXPLOSIVES.

IN view of the fact that a great many workmen and perhaps workwomen also in Canada will soon be engaged in loading high explosive shells for the use of the Allies, some recent observations by Hudson Maxim, a famous inventor of explosives, regarding the relative safety of tri-nitro-toluene, which will be used very largely, will be reassuring. He says:

"High explosives had been pretty well perfected before the outbreak of the great war. Nevertheless, we have received reports of some astonishing effects produced by the French turpinite and the Austrian skeds shell. It has been reported that so dreadful is the concussion produced by the detonation of the new high explosive that troops are killed by the mere concussion even to a distance of a hundred yards. Such results are highly improbable, for it is impossible to make a high explosive which will develop more force than results from the volume of gases liberated and raised to a high temperature by the chemical reaction of detonation.

"Picric acid and nitrogelatin come very near to the limits of the possible in power of high explosives. Turpinite is probably picric acid or a picric acid compound, but on account of the scarcity of picric acid at the present time it is probable that the more easily available tri-nitro-toluene is largely used instead. Tri-nitro-toluene, although not so powerful as picric acid or ntiro-gelatin, is yet exceedingly powerful. It is also so insensitive that not only may projectiles charged with it be fired with perfect safety from cannon at high velocity, but also projectiles charged with it may be fired through armor-plate without being exploded by the impact, so that they will pass to the interior of a war vessel to be exploded by a delay-action detonating fuse."

Shell loading is a new business in Canada, and it is comforting to learn that the explosive likely to be most largely used in "fixing" the ammunition can be handled without excessive danger.

The Spelter Outlook.—A large United States producing interest quotes spelter deliveries around the end of the year at 16½ to 17 cents, and spot metal 18 to 18½ cents. The scarcity of spot spelter has been largely overcome by the output of the smelters. Export orders have dropped off, and although exports have been large over recent months, these shipments represent orders placed some time ago.

Strengthened Aluminum. —While aluminum is made more suitable for many mechanical purposes by alloying with 9 to 12 per cent. of cobalt, it is still too coarsely crystalline to be strong, but in remedying this by adding a little tungsten or molybdenum, alloys have been obtained three times the tensile strength of pure aluminum. The best results were obtained with 0.8 to 1.2 per cent. of tungsten and 8 to 10 of cobalt, or 0.6 to 1 per cent. of molybdenum and 9 to 10 of cobalt. Increasing the tungsten or molybdenum and cobalt adds to the tensile strength but makes forging and rolling more difficult, the tungsten alloys being somewhat harder than the molybdenum.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

SHELL NOSING AND BANDING HYDRAULIC PRESSES.

IN the manufacture of shrapnel and high explosive shells after they have been forged and drawn into shape, two hydraulic pressing operations are necessary—that of nosing the shell and then pressing or shrinking the copper band around it. The Hydraulic Press Manufacturing Co., Mount Gilead, Ohio, are now building hydraulic presses for both of these operations, as well as for the forging and drawing operation, to the order of both United States and Canadian manufacturers who are engaged in the production of these munitions of war.

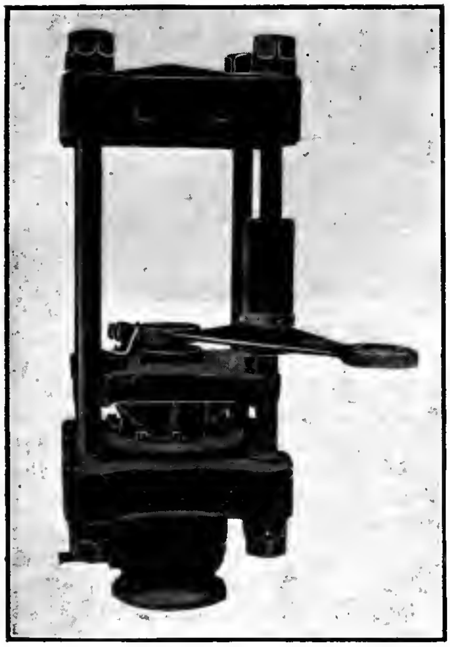


FIG. 1. SHELL NOSING PRESS.

Shell Nosing.

Fig. 1 illustrates an upward pressure type of press which is used for nosing or pointing the shell after it has been formed from the solid steel billet, drawn into shape and later machined. The end of the shell is heated and set in a centering die on the platen of the press. A die, having a conical shape to correspond to the nose of the finished shell, is attached to the head of the press. The shell is then forced into this side and the edges turned in. A two-arm revolving loading attachment wroks upon one strain rod. This revolving attachment has a capacity for receiving two shells, one on each end, thus enabling the operator to have a shell in constant waiting to undergo the nosing operation.

The nosing press is capable of exerting a maximum pressure of 150 tons, and is solidly built, steel being used throughout in its construction. The press is operated either direct from an independent pump or from an accumulator system.

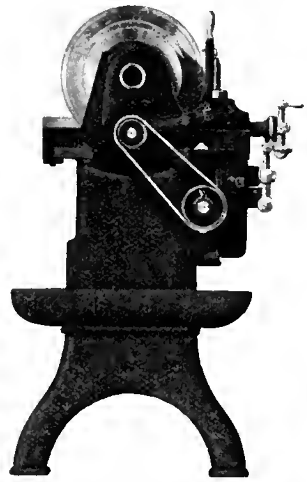
Banding Operation.

After the shell has been pointed, the next pressing operation is that of shrinking the copper band around the base of the shell. For this purpose, the four-cylinder horizontal press, Fig. 2, has been designed. The rams from the four cylinders press in from four directions, thus taking care of four sides of the band at once. To properly secure the band at all points the shell is turned two or three times. From 20 to 75 tons pressure is necessary for the work. During the pressing operation the shell is supported in the centre of the press by an adjustable table or stand from beneath the heads of the rams. The maximum pressure capacity is 75 tons. The press is operated from either an independent pump or from an accumulator system.

NEW MANUFACTURING LATHE.

THE advent of the shell industry has served to impress manufacturers with the economies which can be effected through the use of single purpose machines. The manufacturing lathe is a machine of this type, its work being confined to plain turning of the heaviest kind, complete facilities for rapid and accurate handling of the work being provided.

A recent machine of this type has been put on the market by the Rockford Tool Company, Rockford, Ill., which embodies all the elements of power, accuracy and simplicity. It swings $16\frac{1}{2}$ inches over the bed, has a three step cone with a maximum diameter of 13 inches, and a belt width of 4 inches, enabling ample power to be supplied to the lathe spindle. A two speed friction countershaft makes six speeds available.



END VIEW 16-IN. MANUFACTURING LATHE.

The spindle is made from a crucible steel forging, and runs in Babbitt metal bearings, the Babbitt metal being seated

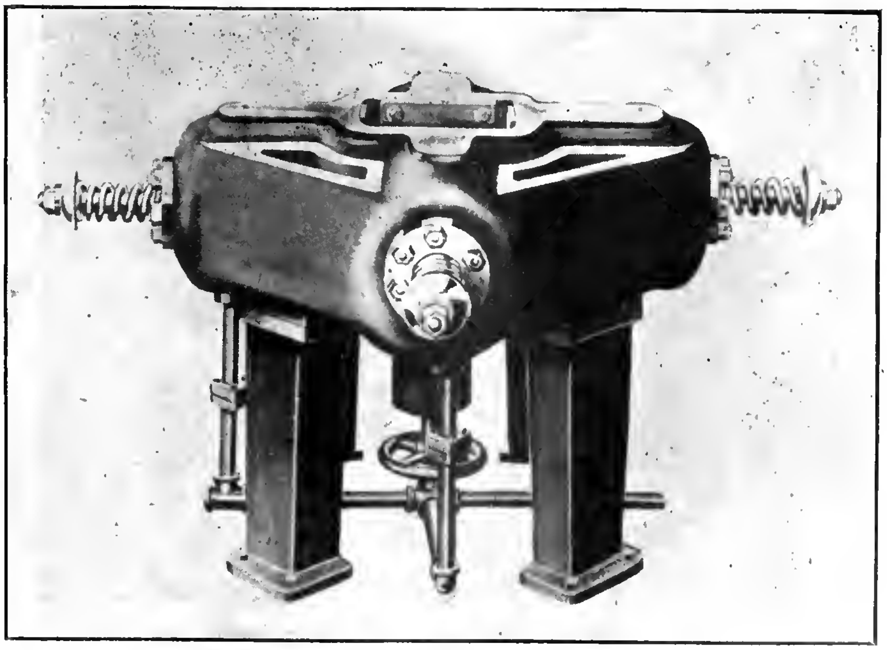


FIG. 2. FOUR CYLINDER BANDING PRESS.

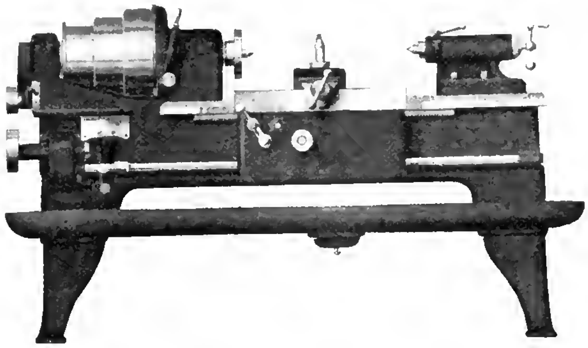
in dovetail slots. The spindle has a front bearing $2\frac{3}{4}$ inches in diameter by $6\frac{1}{4}$ inches long, with provision for ample lubrication. A 1 7-16 inch hole is provided in the spindle. A control lever is installed which operates a powerful friction clutch and applies a brake, while the two speed countershaft allows the work to proceed without interruption due to throwing in back gears, etc.

The bed is deep, well ribbed, and has special wide V's. A 6 ft. bed takes 26 inches between centres. The tailstock is clamped with two heavy bolts and can be set over for turning tapers; the spindle bearing is $2\frac{3}{8}$ inch dia. x 9 inch, long.

A heavy plain rest is supplied, having a slide $7\frac{1}{2}$ inch wide, provided with taper gibs. The cross feed is by hand only, the feed screw having a large diameter dial graduated in thousandths. Four longitudinal feeds are furnished varying from 15 to 105 threads per inch.

The two speed friction countershaft runs at 80 and 225 revs. per min., the pulley being 14 inches dia., for 4 inch belt. A large pan for oil and chips is regularly furnished.



16-INCH MANUFACTURING LATHE.

MAGNETIC BRAKE.

MACHINE shop and mill operators will be interested in the new alternating-current magnetic brake described below. It has been designed especially for use with induction motors, operating cranes, hoists, roller lift bridges, and many different classes of mill machinery, and is applicable wherever frequent stops and reversals are necessary. The operating magnet is single-phase and may, therefore, be used on polyphase circuits.

The action of the brake is simple. When the controller is thrown to the off position, two brake shoes are forced by means of springs against a cast-iron brake wheel which is keyed to the motor shaft. When the motor is started, the magnet coil is energized and the action of the magnet, operating through a lever and a toggle, forces the shoes apart and releases the brake.

In the design of this brake, the Westinghouse Electric Manufacturing Co. have embodied several improvements. It is a complete self-contained unit that can be mounted directly beside the motor or on a special sole plate. Since the application of its braking action is not dependant upon gravity, it can be mounted in any position, from the horizontal to 90 degrees in such a direction that the movable magnet lever has no tendency to fall away from the stationary magnet core. This makes it especially desirable for application where the position of the motor changes during the operation, as on a roller lift-bridge.

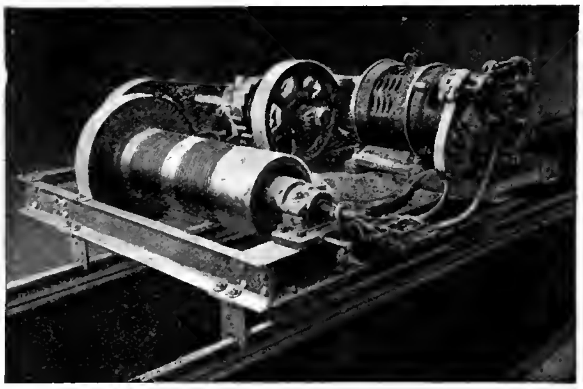


FIG. 2. TYPE "A" BRAKE APPLIED TO CRANE MOTOR.

The overall height has been reduced to a minimum, so that it can be used in places where head room is limited, as, for instance, in crane service. The insulation is such that the brake is adaptable for use outdoors and exposure to the weather without any modification whatever. No dashpots are used, thus all possibility of trouble due to sticking is eliminated. The brake shoes are made of cast-iron to which are fastened woven asbestos fabric linings. The wheel is made of cast-iron, and the coefficient of friction between the brake wheel and shoes is not materially affected by oil, grease or water.

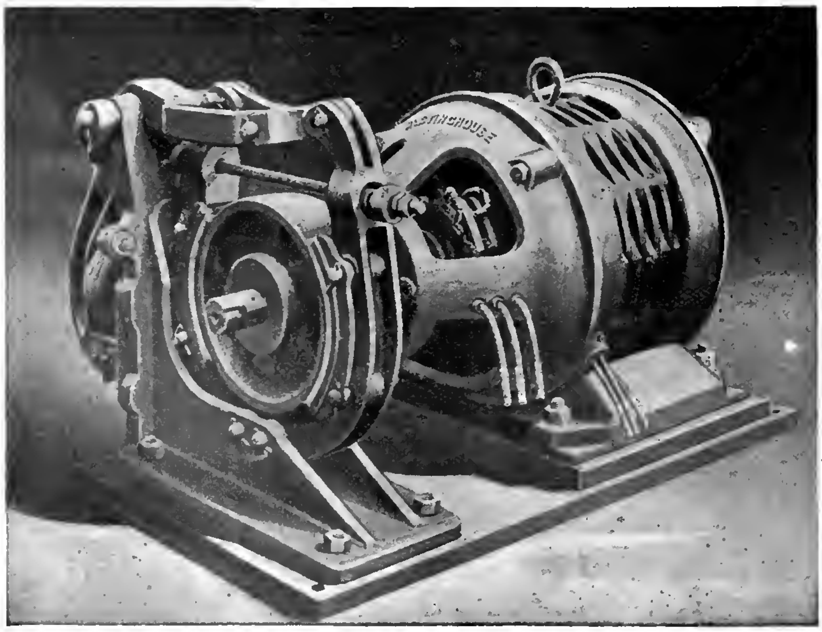

FIG. 1. TYPE "A" BRAKE APPLIED TO POLYPHASE MOTOR MOUNTED ON SOLE-PLATE.

The pressure on the brake shoes can be varied by means of nuts on the spring rods, and wear on the shoes can be taken up by means of an adjusting screw. Two springs are used and only two adjustment points are necessary. If the operator fails to take care of the adjustment which compensates for wear on the shoes, the result will not be a failure of the brake to set, it will only mean that the machine cannot be started, as the brake will not release. With a view to facilitating repairs, axle steel pins held in place by cotter pins have been used wherever possible. A pair of pliers and screwdriver are the only tools necessary, to completely dismantle or assemble the brake.

CANADA'S DESTINY—AFTER THE WAR, WHAT?

TO every branch of Canadian industry, the war comes home more closely each week. There are few persons in Canada to-day who do not have a relative, friend, or acquaintance on active service in Europe, and there are just as few who are not engaged or interested in the industrial activity which is necessary to maintain our soldiers in the field.

The total value of war orders placed by the British Government with Canadian firms reaches the enormous sum of $230,000,000, and the fact that over 75 per cent. of this has been on account of munitions of war alone serves to show how intimately the present prosperity of our engineering industry is associated with the war.

These figures relate to British contracts only and do not take account of the further huge sums involved in similar contracts with Russia and France. The feverish activity, the numerous extensions to plants, the branching out into various kinds of work by firms which would never have dreamt of such operations in peace time; all these and other conditions, while due to the exigencies of the moment, are having an effect on Canadian industry, which, though likely to be more marked in the immediate future than at a later period, will be none the less permanent and beneficial to the moral and commercial life of the nation.

A leading technical journal in Britain points out one direction in which the ultimate triumph of the Allies will indirectly benefit the world. The Engineer says: "To a quite regrettable and quite unnecessary degree we have for some years relied upon Germany for certain classes of brain and certain kinds of material. If the war had been short we should not have accustomed ourselves to do without these commodities, and in the course of a few years after its conclusion we should have returned to the position of the spring of 1914.............. We must henceforth rely upon ourselves, upon our own British science and inventiveness, upon the genius of our own people. It is said that science is international, that it knows no boundaries or frontiers. That we admit, but, on the other hand, technology, the application of science to industry is distinctly national. It is influenced by a score of things peculiar to the people, and to the country in which they live........"

These sentiments contain the germ idea from which shall develop the conditions and moral standards, on which the destiny of Canada must ultimately rest. Honesty, national and individual is the cornerstone of all permanent greatness. Germany was not honest. The ultimate object of all nations should be to "Live and let live," or rather "Live and help to live." How much importance was attached to this principle of existence by the enemy is evidenced not so much by his conduct of the war as by his actions before, as disclosed by recent events. The glorification of German genius by organized government departments was so successful, the stage managers succeeded so well in monopolizing the centre of the world stage that people began to think there was no nation like to Germany. Facts are now coming to light which show that a highly boosted German inventor was not the genius which the world had been told he was. His original invention was a complete failure, and only the development of his idea by others on totally different lines, and subsequent perfection of it by British engineers saved his name from oblivion.

Careers of this description develop a tendency in Anglo-Saxon nations to belittle the achievements of their own workers, and in manufacturers to decry the efforts of those employed by them. Opportunity is necessary for the development of everything, and the experience of engineering firms in Canada in overcoming the difficulties encountered in producing munitions of war, should remove for all time that prejudice against home genius and products.

Many workers are engaged now on work which hitherto was absolutely strange to them. Manufacturers have had to rely on subordinates to help them out of tight corners which they could never have gotten out of unaided. Draftsmen, toolmakers, machinists, all have had to do things and think things, which in the normal course of events they would never have done. Science, which knows no restraints either in production or distribution, will continue to be international. Technology, the application of science to industry will continue to be national. The Canadian ship of industry has truly found herself, and even now in the hour of national effort, her course is being set so that when the work of recuperation is at hand, her efforts and ability shall not be least internationally.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., August 16, 1915.—The present industrial situation is little changed from that of a week ago, although a slight improvement is noticeable in the steel trade. The shell industry still has quite a call on steel bars for the manufacture of shrapnel and high explosive shells, and the continued improvement in the steel outlook is largely due to the constant demand for material in connection with war contracts generally.

Steel.

Canadian steel mills are now working to capacity to keep up with the demand for steel bars and billets for the filling of war orders and also to take care of further orders which may be placed at any time. If satisfactory conditions prevail in Canada for the completion of finished shells it is more than probable that still larger orders will shortly be placed for varied type shells. Prices remain firm on bars, plates, etc., but a slight reduction is evident on galvanized sheets.

Pig Iron.

Improvement in pig iron is scarcely noticeable although a slight betterment of conditions seems to prevail.

Scrap Metals.

Quotations on the scrap metal market continue firm and little change, if any, falls to be recorded.

Machine Tools and Supplies.

The demand for machine tools has fallen off from that of a few months back, but, although heavy specialties are not so much in request, machine tool supplies show little easing up in demand. High speed steel maintains its abnormally high price and every indication points to its going still higher.

Metals.

Quotations for the various metals are somewhat easier than those of the previous week; slight declines being noticeable in the prices of copper, spelter and lead.

Toronto, Ont., Aug. 17.—An interesting development in the metal industry as a result of the war is the announcement that refining plants for treating copper and zinc will be established at Trail, B.C., and other points. This will help considerably in keeping the cost of these metals on a reasonable basis and also make the trade independent of outside sources. In this connection it is reported that a plant for refining zinc will be established in Welland, Ont. The extent to which Canada is benefiting by war orders is shown in an official statement recently issued by the Department of Trade and Commerce. The British Government alone has placed orders to the value of $230,000,000 with Canadian manufacturers for equipment already made or in process of manufacture. Of this sum $188,183,180 represents the expenditure on munitions. In addition are contracts placed by the other Allies, the particulars of which have not been published but will in the aggregate amount to a considerable sum.

An optimistic spirit prevails in business circles with regard to this season's crop, very favorable reports continue to be sent out from various points in the West and a large yield is expected. On this account the outlook for trade is favorable and in conjunction with the war business, industrial conditions are on a sounder basis than at any time since the war started. The greater part of the trade being done now is for export, the domestic demand being comparatively light although improving.

Steel Market.

War orders continue to keep the mills fully employed and there is every indication of present conditions prevailing for some time to come. The revenue statements of the various iron and steel companies are a good indication of the improvement that has taken place in the trade during the past year. The business is almost entirely for export either directly or indirectly. Domestic business is still dull. The railways have been out of the market for several months, there being very little constructional work in progress. The building trade is showing no indications of improving this year and municipalities are not doing much in the way of buying cast iron or steel pipe. Quotations are holding very firm for domestic products, and prices of bars, plates and shapes have advanced to 1.30c f.o.b. Pittsburgh.

There is little change to note in the galvanized sheet situation. Prices have a weaker tendency due to the continued decline in the spelter market but no changes in sheets have been made locally. Some makers continue to keep out of the market but resumption of regular conditions in the galvanized sheet trade can hardly be expected until spelter is at a considerably lower level than at present when sheets can be made at a price which buyers can afford to pay for ordinary uses.

There is no change in the high speed tool steel situation and considerable difficulty is still being experienced in obtaining supplies of tungsten. Heavy demand and low stocks further complicate the situation. The growing scarcity of chromium is regarded as a factor likely to augment the increasing price of high-speed tool steel.

Conditions in the steel trade in the States continue to improve on account of war orders. The demand for steel bars is extremely active and deliveries are becoming much more extended. Prices are very firm with a higher tendency.

Pig Iron.

The pig iron situation is unchanged. There is a good demand for steel-making pig iron but foundry iron is quiet. Owing to the activity in the steel trade in the States the pig iron market is very firm and some brands have advanced, grey forge being now quoted at $13.95 Pittsburgh. Most of the Canadian mills use their own pig iron so the local market is not affected materially.

Machine Tools.

Considerable activity prevails in the machine tool trade but the situation generally is unchanged. Although no further orders for shells have been placed recently, manufacturers who have received orders for these but have not yet started work on them, are equipping their plants and buying the necessary machinery. The unusually heavy demand for machine tools in the States is making deliveries very slow while Canadian makers of tools are also very busy filling orders. Owing to these conditions there is a brisk demand for second-hand equipment with special tooling fixtures for shell work.

Supplies.

Satisfactory business is reported in machine shop supplies, and prices are generally holding very firm. Brown & Sharpe cutters have advanced 10 per cent. Waste is expected to advance, but no change in prices has been made at present. Half-and-half solder has declined owing to weakness in the tin market, and is now quoted at 26¼c per pound. The linseed oil market is very unsettled, and prices have declined 2c, raw oil being now quoted at 65c and boiled at 68c per gallon. The turpentine market is now quoted at 64c per Imperial gallon.

Scrap Metals.

The scrap metal market is unsettled and weak, with a falling off in demand. Export business has been curtailed on account of the present financial situation and adverse rate of exchange. A number of price changes have to be noted. Cop-

per, No. 1 composition, brass turnings and scrap zinc have all declined, and may go lower still, there being a tendency in that direction. Heavy melting steel is in good demand, and quotations are very firm at the advance. The lead market is weaker, but prices are unchanged. There is little demand for cast iron scrap, and the market is dull and prices unchanged.

Metals.

A general weakness prevails in the metal markets, and further declines in prices have to be noted. Tin, copper, spelter and lead are all lower and show no sign of any immediate reaction. Spelter, while considerably below the high level attained a short time ago, is still too high to be on a commercial basis, and the situation is not greatly changed because of this. The building of new smelters now in progress may help to keep this metal at a more reasonable price. The antimony market is unchanged, and quotations are entirely nominal. There is a good demand for aluminum and supplies are scarce. The market is firm and quotations unchanged. All solders have declined due to weakness in the tin market.

Tin.—The market is still declining in London, and buyers are showing less confidence. Although the tin position is good, the market is being affected by the general depression in the metal trade. Tin has declined 1c, and is being quoted at 40c per pound.

Copper.—The market is unsettled and weak in London, with a corresponding influence in New York. The situation is generally unchanged except that production is increasing, but buyers are showing a lack of confidence, and are more economical in their purchases. The market locally has declined 1c, and lake copper is now being quoted at 20c per pound.

Spelter.—The market is demoralized and continues to decline, not having any support. The decline is affecting brass mill spelter, and not high-grade metal, which is being held at 30c at New York. Local quotations have declined 3c, and are nominal at 20c per pound.

Lead.—The market is dull and weak in London, but the present "Trust" price of 4½c, New York, has put the market in a steady position. Lead has declined ½c, and is being quoted at 6½c per pound.

Antimony.—The market is firm, but buying has fallen off. Quotations are unchanged and nominal at 40c per pound.

Aluminum.—There is a good demand for aluminum, but supplies are scarce. Quotations are firm and unchanged at 40c per pound.

CANADIAN IRON AND STEEL IN 1914.

THE statistics gathered by the American Iron and Steel Institute show that the output of pig iron in Canada in 1914 was 705,972 tons, against 1,015,118 tons in 1913. In 1912 Canada's pig iron production was 912,878 tons and in 1911 it was 824,368 tons. Of the 1914 total, 690,880 tons was coke iron and 15,092 tons charcoal iron. The number of furnaces in blast in Canada at the end of 1914 was 6; the number out of blast, 16. The production of pig iron by grades in 1914 was as follows, comparison being made with 1913:

	1914	1913
Basic	331,456	558,524
Bessemer	184,053	227,662
Foundry	174,346	225,231
All other	16,117	3,701
Total	705,972	1,015,118

Steel Ingots and Castings.

The production of steel ingots and castings in Canada in 1914 was 694,447 tons, of which 675,691 tons was ingots and 18,756 tons castings. The production of open-hearth steel was 549,716 tons, of Bessemer steel 144,447 tons, and of other kinds 284 tons. The total of 694,447 tons includes about 4,800 tons of alloy treated steel ingots and castings, against about 1852 tons in 1913.

Finished Rolled Products.

The production of finished rolled products in Canada in 1914 was 659,519 tons, against 967,097 in 1913. The production of rails last year was 382,344 tons, against 506,709 tons; of structural shapes and wire rods, 59,050 tons, against 68,048 tons; of plates and sheets, nail plate, merchant bars, tie plate bars, etc., 218,125 tons, against 392,340 tons. The production of rolled iron products in 1914 was 47,309 tons, while the production of rolled steel products was 612,210 tons.

Cut and Wire Nails.

The production of iron and steel cut and wire nails in Canada in 1914 is estimated at 1,144,000 kegs, as compared with an estimated production of 1,520,000 kegs in 1913.

PRODUCE AND REFINE ZINC AND COPPER FOR THE ALLIES.

AS A result of arrangements now completed, it has been announced by General Bertram, that Canada will not only manufacture shells for the Allies, but will produce and refine for the first time in this country the zinc and copper required for the ammunition.

These arrangements represent the fruition of the desire and efforts of General Hughes, minister of militia. It was not long after Canada had commenced the manufacture of shells for Great Britain before the securing of copper and zinc for their production became a problem. Although Canada produces both these metals she has not hitherto had facilities for refining them. Consequently every ton of such ore produced in the Dominion had to be sent to the United States, and there refined before being bought back again by Canadians.

United States refiners took advantage of this situation shortly after Canada commenced the manufacture of shells by raising the price of refined copper and zinc to exorbitant levels. It is understood that by forming a combination among some Canadian capitalists and bucking the monopoly General Hughes succeeded in getting the price reduced somewhat. However, it became apparent that if the Dominion were to enter seriously into the manufacture of munitions it must have refineries of its own and efforts toward that end were initiated.

Several conferences have been held between the Shell Committee and the Cabinet. The result is contained in the statement of General Bertram that agreements had been made and were closed up for the refining at Trail, B.C., and other points, of both copper and zinc.

WAR SUPPLIES FROM CANADA.

VERY general interest is being taken by producers and manufacturers as to war supplies provided by Canada, mainly as regards the British Government and, in a lesser degree, as regards the Governments of the Allies. The question as to whether as much is being supplied from Canada as can reasonably be provided is being thoroughly discussed, and assertions vary according to the sources of the information or the strength of the imagination of the parties thereto.

It is comparatively easy to make a statement of what has been supplied by Canada in respect to purchases made by the Allied Governments through direct agency of the Government of Canada. Reliable statistics are available and the information can be fairly accurately given. For the large quantity of materials, directly or indirectly meant for war purposes, which are purchased in Canada outside of direct Government contract, greater difficulty is experienced in coming even at approximate values. The Department is taking steps to get information in regard to this branch of supply, but lack of knowledge of the private parties and corporations that are interested renders the task somewhat difficult.

As to what is being contracted for by the Governments concerned with companies or private dealers, accurate information is possessed by the purchasing

authorities of each Government, but it is difficult for the Canadian Government to possess itself of these from the Governments concerned. As to indirect supplies, there is a large margin with reference to which it seems impossible to get any information.

We publish herewith, says the Weekly Bulletin of the Department of Trade and Commerce, Ottawa, a statement of contracts and purchases made in Canada by the British Government to date. A great deal of what is shown in the table has already been despatched and paid for. A larger part probably is still under contract for delivery according to the conditions of the contract. It will be seen that the detailed value of orders executed or under execution for the British Government in reference to war supplies amounts to about £46,000,000, distributed over a very considerable area.

Purchases in Canada.

TENDERS FOR SHEET STEEL AND STEEL BANDS.

THE Hon. Phillipe Roy, Canadian Commissioner General at Paris, has forwarded to the Department communications from the Engineer of Equipment and Traction of the Paris-Lyon-Méditerranée Railway, with reference to the probability of Canadian manufacturers being in a position to tender for 600 tons of sheet steel, classes C, D, and E, for current uses, and 200 tons of sheet steel, classes A and B, for boilers. Net prices are requested per 100 kilos for each of these classes of sheet and by thickness, the prices quoted to mean goods delivered free of all transportation charges, customs duty or other expenses and loaded on cars in a station of the above-mentioned railway system. A table, indicating the maximum simultaneous dimensions (length and width) which the Canadian plant can roll in various thicknesses is also asked for, together with the delays of delivery, which the company would undertake to observe.

The Paris-Lyon-Méditerranée Railway Co. has also the intention of entering into a contract for the supply of 1,500 to 1,800 tons of steel bands, classes B and C, for locomotives, tenders, passenger and freight cars, which it will require during a period of six months. The deliveries of this item are asked to be made according to the needs of the Paris-Lyon-Méditerranée Railway Co. on the dates indicated by them, and according to the special orders, which will be forwarded to the sellers two months in advance and which will indicate the types and number of steel bands to be supplied. Specifications and drawings for these tenders when received, may be inspected at the department by Canadian firms, who may desire to do so. The date originally fixed for the closing of the tenders was July 31, but as the P.L.M. Co. has apparently not received sufficient proposals to meet its requirements, the time will in all probability be extended, in order to allow Canadian firms to compete. Further advices are being awaited from the office of the Canadian Commissioner General at Paris and any additional information will be referred to interested manufacturing companies, after its transmission to the Department of Trade and Commerce, Ottawa. (Refer to File No. 1750).

WAR ORDERS REJECTED.

A CANVASS of leading manufacturers of the United States reveals, says the New York "American," an increasing number who refuse to accept war orders. Those who declare they will not prolong the European war, and the orders aggregating more than $139,100,000 which they have turned away, are as follows:

The Ford Motor Co., $15,000,000.

Ball Engine Co., of Erie, Pa., shrapnel shells, $10,000,000.

The Fischer-Sweeney Bronze Co., of Hoboken, supplies, $1,000,000.

The Essex Novelty Co., of Berkeley Heights, N.J., munitions, $500,000.

The Empire Art Metal Co., of College Point, New York City, shrapnel shells, gun barrels, $1,500,000.

Bosch Magneto Co., New York, electrical devices, aeroplanes, arms and machinery, $12,100,000.

Imperial Metal Manufacturing Co., of Long Island City, shrapnel, $400,000.

Dietrich Bros., Baltimore, $2,000,000.

Excelsior Tool & Machinery Co., of St. Louis, cartridges, $600,000.

Aldrich Manufacturing Co., of Buffalo, 300,000,000 brass shells, $5,000,000.

Eagle Manufacturing Co., Wellsburg, Va., brass shells, $1,000,000.

Driggs-Seabury Ordnance Corporation, Sharon, Pa., arms and big guns, $2,000,000.

Textile Machine Works, Wyomissing, Pa., $500,000.

Burroughs Adding Machine Co., Detroit, $1,000,000.

Republic Metalware Co., Buffalo, N.Y., 2,500,000 cartridges and other orders, $86,000,000.

Bronze Powder Co., of Elizabeth, N.J., powder, $500,000.

Heller Forge Works, East St. Louis, shrapnel casings, unavailable.

United Engineering & Foundry Co., Pittsburg, Pa., ammunition, unavailable.

Commonwealth Steel Co., Granite City, Ill., unavailable.

Herring-Hall-Marvin Safe Co., unavailable.

Colburn Machine Tool Co., Franklin, Pa., unavailable.

Owensboro Wagon Co., Owensboro, Ky., unavailable.

Globe Malleable Iron & Steel Co., Syracuse, unavailable.

Builders' Iron Foundry, Providence, unavailable.

Michigan Copper & Brass Co., Detroit, unavailable.

Cushman Chuck Co., Hartford, Conn., unavailable.

Warner & Swasey Co., Cleveland, unavailable.

National Acme Manufacturing Co., Cleveland, unavailable.

LUMBER TRADE IMPROVES IN NEWFOUNDLAND.

THE lumber export trade from this colony, which has been almost non-existent for the past few years, has been brought into prominence again by conditions growing out of the war. A great demand has developed in Great Britain, not only for pit props for the collieries, but for lumber for general purposes. Lumbering concerns throughout the island, which have been operating entirely for the local trade, have decided to go into the export business on an extended scale.

The export of pit wood alone for the year is estimated at 200,000 tons. A regular fleet of steamers has been engaged for several months in transporting this material from Newfoundland and Eastern Canada, the British collieries having been unable to secure their usual supply from Europe because of the closing of the Baltic Sea and the lumber requirements of the allied armies in France.

During the past 10 years most of the soft wood logs cut in the colony and not needed for local construction have been sent to the pulp mills for use in the large paper-making industry, which has grown up during that period.

BOUNTY TO FOSTER ZINC PRODUCTION.

A SLIDING bounty not exceeding 2 cents per pound, and not payable until the end of the war, has been granted by the Government on Canadian zinc production, with a view of obtaining supplies of this metal for the manufacture of munitions.

A committee of the Government under the chairmanship of the Minister of Finance, after full discussion with members of the Shell Committee, has thus satisfactorily solved the problem of ensuring at reasonable prices a Canadian supply of zinc suitable for use in the production of brass for the making of quick-firing cartridge cases for shells.

Before the outbreak of war, this quality of zinc sold at about eight cents per pound. Since that time the price has steadily risen as high as forty cents and grave fears were entertained that the supply might be entirely cut off. At present, the sources of supply are outside of Canada.

The Shell Committee, representing the British Government in the purchase of shells in Canada, regarded it is absolutely necessary that there should be supplies of this zinc within Canada. Canadian producers were unwilling to go to large expense of installing refineries unless insured against the fall in zinc prices which is inevitable after the close of the war. After considerable negotiation, the Government decided to offer a limited bounty for the production in Canada of zinc, the offer being as follows:—

Bounty Details.

Bounties on a sliding scale, not exceeding two cents per pound, will be granted upon production in Canada from Canadian ores of zinc, containing not more than 2 per cent. impurities, when the standard price of zinc in London, England, falls below £33 per ton of 2,000 pounds, provided that bounties shall not be payable on zinc produced before the expiration of the war or after the 31st day of July, 1917, or on zinc contracted for the Shell Committee at a price of 8 cents or over per pound, total amount of bounty to be paid not to exceed $400,000.

As a result of this action on the part of the Government the Shell Committee, on behalf of the Imperial War Office, has been able to contract for several thousand tons of zinc at very reasonable rates with a further reduced rate for further deliveries.

It will be observed that the object of the bounty is to insure the producers against too great a fall in price in the period between the end of the war and the 31st July, 1917. The bounty will give an impetus to the refinement of zinc in Canada and serve the purpose of ensuring a certain supply of brass to the Shell Committee.

ALLIES' PURCHASING AGENTS.

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:—

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendance Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Attache, Russian Embassy, Washington, D.C.

ORDERS FROM FRANCE COMING TO CANADA.

IT is reported from London that Canadian munitions manufacturers may look forward to receiving substantial orders from the French Government in the near future. For the past two or three weeks representatives of various Canadian groups have been conferring with the French war authorities, with the result that a well-known general, who is recognied as an expert in all that relates to heavy ordnance, has been deputed to proceed to the Dominion to go into the whole question of supplies on the spot. As already pointed out, the French Government were favorable to setting up an additional plant for the manufacture of munitions on French soil rather than to buying outside of France, but as the outcome of last week's conferences this policy was abandoned for financial reasons.

Chambers, Ltd., 80 Don Esplanade, Toronto, are building an extension to their factory and will instal a sherardizing furnace.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Oshawa, Ont.—It is reported that a syndicate propose installing a steel plant here.

Kincardine, Ont.—Fire in the pattern shop of the Hunter Bridge & Boiler Co. works here did about $15,000 damage.

Petrolea, Ont.—The pumping outfit on King Street, owned by the J. & J. Kerr Co., was destroyed by fire on August 16.

Toronto, Ont.—The Chevrolet Motor Co., of New York, have purchased the plant and premises of the Dominion Carriage Co., and will install equipment for making motor cars.

Welland, Ont.—The Canadian Zinc Co., recently incorporated with a capital of $500,000 will build a smelter here. The Quality Beds factory has been leased, with an option of purchase. C. H. Massey, of Sherbrooke, Que., is interested in the enterprise.

Niagara Falls, Ont.—The Standard Smelting and Refining Co., of North Bay is extending its business by establishing a plant just up the Niagara river from Chippewa, where it has secured the mills of the British-Canadian Smelting Co. A large building some 80 feet long, is now being erected, with others to follow.

Vancouver, B.C.—It is reported that the establishment of a steel rolling mill has been arranged between an eastern Canadian firm and Port Moody city council. Details have been discussed between representatives of the firm and the mayor and council, and will be embodied in a formal agreement. The firm has secured 35 acres at the head of the Inlet and the council have agreed to guarantee $100,000 on adequate security.

Municipal

Grimsby, Ont.—The town contemplate installing a waterworks system at a cost of $5,600.

Chatham, Ont.—The Water Commissioners are considering installing hydro power at the pumping station.

Toronto, Ont.—Works Commissioner Harris has reported against the city establishing car shops which would cost $285,000.

Listowel, Ont.—A by-law is to be submitted on Aug. 21, to authorize the installation of a waterworks system to cost $5,400.

St. Thomas, Ont.—City engineer Ferguson has prepared a plan for a city storm sewer system. The estimated cost is $52,230 including excavation, pipe, manholes and catch basins.

Ottawa, Ont.—The by-laws have passed to raise $100,000 to provide for the cost of the construction of an abattoir and $50,000 to provide for the cost of an additional incinerator.

Rodney, Ont.—The by-law to loan the Rodney Woodenware Co., $5,000 to rebuild their factory was defeated. The by-law to purchase the franchise of the Rodney Gas & Water Co., was also defeated.

CANADIAN GOVERNMENT PURCHASING COMMISSION.

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George Gault, Winnipeg; Henry Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Matheson, Ont.—The town council are considering the construction of a pipe line to White Fish Lake to increase the water supply. A by-law has been passed to sanction an expenditure of $20,000 on the scheme. McAustin and Anderson, of North Bay, Ont., are the engineers.

General Industrial

Calgary, Alta.—The Southern Alberta Refineries, Ltd., will instal an oil refining plant.

St. Thomas, Ont.—Mr. Fitzpatrick, of Belmont, near here will rebuild his factory which was destroyed by fire.

Saskatoon, Sask.—It is announced that an important canning company in Ontario propose establishing a plant here for canning peas.

St. Thomas, Ont.—The plant of the St. Thomas Packing Co., took fire on Aug. 10, and was considerably damaged. The cold storage equipment was not injured.

Ingersoll, Ont.—John Hayman & Sons, of London Ont., are the contractors for the $30,000 addition to the factory which the Borden Milk Co., will build here.

Collingwood, Ont.—Lacking twenty-eight votes to make up the required two-thirds majority, the by-law to loan the Bryan Manufacturing Co. $20,000 without interest was defeated on Aug. 11, the vote standing: For 520, against, 302. The company in addition to rebuilding its planing mill intended to erect a factory for the manufacture of woodenware.

Building Notes

Toronto, Ont.—A public library will be built at Kew Beach, to cost $20,000. Eden Smith & Sons, Toronto, are the architects.

Sherbrooke, Que.—The tender submitted by the Loomis Deakin Co. for a new city hall has been recommended for acceptance at $7,400.

Windsor, Ont.—Announcement is made here that contracts have been let and work will shortly be commenced on a new $200,000 building for the Merchants Bank. The site chosen is at Oulette avenue and Chatham street.

Montreal, Que.—A syndicate of Boston, New York and Chicago capitalists have purchased a site here and propose erecting a ten-storey hotel, to cost one million dollars. The Corner Realties Syndicate of Montreal are interested.

St. Thomas, Ont.—A building permit has been issued for the construction of the new Huron and Erie office building. The structure will be two storeys high, 30 feet by 60 feet, and will cost $15,000. Excavation was commenced a few days ago.

Regina, Sask.—The Robert Simpson Co., of Toronto, Ont., have awarded the general contract for their new distributing warehouse to Wells Bros., of Chicago, Ill. The building is to be of reinforced concrete, eight stories high, 250 by 100 feet.

Port Hope, Ont.—The Port Hope Hospital, Trust has awarded the contract for the new hospital to W. J. Trick

Some Reasons for Locomotive Piston Ring Failures

By "Melter"

The writer discusses from a practical standpoint, the various factors which affect the life and service of locomotive piston rings. It is evident from the article that the entire responsibility cannot always be attributed to any one cause—either making or using. By the application of proper care in manufacture, and reasonable attention in service, the life of piston rings may be considerably prolonged, and efficiency in service greatly increased.

FROM time to time much has been written concerning various causes of piston ring failures in locomotives using superheated steam, some failures being due to one cause and some to another. Most cases of failure, however, are due rather to a combination of circumstances than to any one in particular.

Classification of Causes.

Causes of breakage, excessive wear, and loss of spring in piston rings may be divided into two main classes, viz.:

A.—Manufacture; consisting of (a) material and (b) workmanship.

B.—Service; consisting of (a), class of engine, i.e., passenger non-drifting, or freight drifting; (b), lubrication, and (c), superheat.

Proper Material Necessary.

Regarding Class A, the selection of suitable material is all important, no subsequent care in manufacture or service being able to prevent the development of defects due to improper composition. The American Foundryman's Association recommends the following analysis:

	Per Cent.
Silicon	1.50 to 2.00
Sulphur, under	.08
Phosphorus	0.30 to 0.50
Manganese	0.40 to 0.60
Total carbon	low.

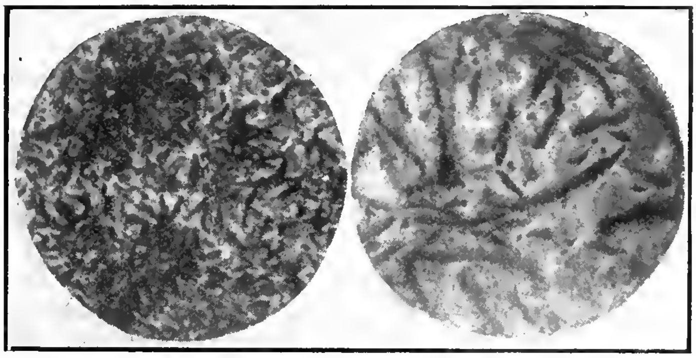
As far as general results are concerned, any close-grained iron comparatively free from oxides will do, but the best results can only be obtained from close-grained rings with the following composition:

	Per Cent.
Silicon from	1.20 to 1.30
Sulphur under	.08
Phosphorus under	.45
Manganese	.40
Graphitic carbon	2.30
Combined carbon	0.70
Total carbon	3.00

This analysis makes a satisfactory ring so long as the combined carbon does not exceed .80 per cent., otherwise the rings will be rather brittle and have a tendency to lose their spring or break. Samples of this mixture when etched with nitric acid should show a structure similar to A, Fig. 1. The dark portions indicating the graphite are small, close together and evenly distributed. The specimen shown at B, Fig. 1, shows the graphite in large bodies, widely separated and unevenly distributed. The comparative suitability of these two specimens is readily apparent to even the untrained eye.

Composition and Cost.

Some concerns use an air furnace to produce their piston ring iron and a good mixture is 33 per cent. pig iron, 10 per cent. steel and 57 per cent. selected scrap. Additions of ferro-manganese, which is used as a deoxidizer, say, 3 lbs. of 80 per cent. alloy to 1,100 lbs. of metal, may be put in the ladle to give greatest efficiency. A test bar from this mixture 1¼ in. diameter, cast vertically in dry sand and tested transversely on 12-inch centres, will give a load of about 3,800 lbs., and a deflection of 38 ins. The tensile strength would be about 29,000 to 32,000 lbs. per square inch, while the cost based on pig at $19.50 per ton, scrap at $17.50 per ton, ferro-manganese at $53.50 per ton, with low sulphur, and coal at $5, would be roughly about 1½c per lb.



A. CLOSE EVEN GRAIN. FIG. 1. B. OPEN IRREGULAR GRAIN.

Making this iron in a railway foundry, where perhaps 50 tons of iron are melted per day in a 90-inch shell lined to, say, 72 in., is not a very easy matter, as it is difficult to produce a structure, or the analysis that is necessary for good service, but a fair iron may be produced by using 30 pig, 20 per cent. steel boiler plate, rails or spring steel (this is to reduce the total carbon and close the grain) and 50 per cent. cast scrap. The method of working out the analysis is shown in Fig. 2. Mixtures are given for air furnace and cupola iron.

Having obtained suitable material, the

FIG. 2. METHOD OF WORKING OUT ANALYSIS ON AIR FURNACE AND CUPOLA MIXTURES.

question of workmanship arises, as different methods of making the rings have a greater or less influence on the ultimate efficiency. The influence of workmanship commences right in the foundry, and begins with the manner of casting. Some makers cast their rings in the form of a tub or large pipe and cut them off with gang tools on a vertical turret

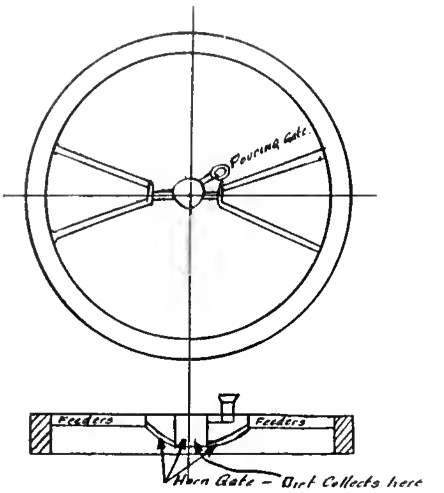

FIG. 3. ARRANGEMENT OF HORN GATE.

lathe or boring machine, while others increase the silicon content so that the rings may be cast singly and still not be too hard to machine. It might be well to state that iron with 1.30 per cent. of silicon is chilled when cast in single rings in a green sand mould, but if the percentage of silicon be increased to 1.60, and the total carbon slightly increased, a good ring will be obtained with correctly tempered sand. It is also best to use a metal pattern. In casting singly, a horn gate is used, as shown in sketch Fig. 3, which collects all the dirt accumulated during pouring.

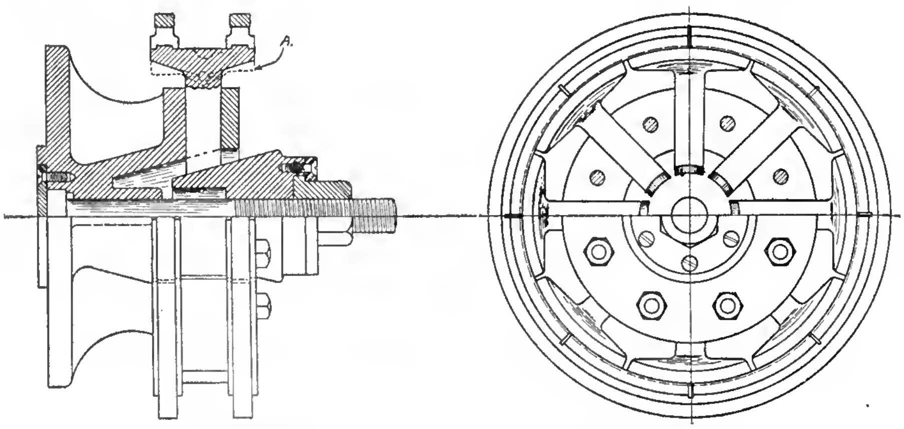

FIG. 4. IMPROVED DESIGN OF EXPANDING CHUCK.

The object in casting single rings is to obtain a denser and harder iron due to the chilling effect of the sand, and the small body of metal compared with a tub and lastly to reduce to a minimum the amount of metal to be machined off, so that the most benefit can be obtained from the superior state of the metal.

Machining.

In machining piston rings which are cast singly, an expanding chuck, Fig. 4, is used with a small modified turret tool holder, mounted on the tool slide, and using $\frac{3}{8}$-inch square tool steel. Only three movements are necessary, a roughing and finishing cut on the sides and a roughing and finishing cut on the face in one movement of the carriage. Gauges are generally furnished, thus securing accurate machining.

The casting is made broad enough so that the edges extend $\frac{1}{8}$ inch over each side of the mandrel, and previous to sending to the machine shop, each casting is thrown into the rumbler barrel and rumbled to remove the sand, after which all burrs or irregularities on the inside of the ring in particular are ground off by the foundry chipping room. The ring next the face plate is slipped on first and placed in position by eye, then the other ring is put in place and the nut tightened. The comparatively large travel of the wedge permits the rings to slip over the mandrels with ease.

The chuck shown in the sketch has been slightly improved as regards practical operation and first cost. Originally there were eight extra pieces, as shown dotted at (A), this piece swivelling on a little roller and the eight sections of the mandrel being held in place by a spring. The present method has proved more satisfactory.

The increased cost of the foundry practice (10 cents per ring, in the case of the single cast ring, as against 40 cents per tub making ten rings), in the one case is counter-balanced by the decreased cost of machining, and in the other case vice versa, whereas in the case of the single ring we have better material. In both instances a ring costs about 40 cents for labor.

Service.

The question of punctuality being of prime importance in passenger service, the opportunities for "drifting" on down grades cannot be taken advantage of to the same extent as with freight engines, where economy has to be maintained. Ordinarily, cylinders receive no oil when the engine is drifting, as the

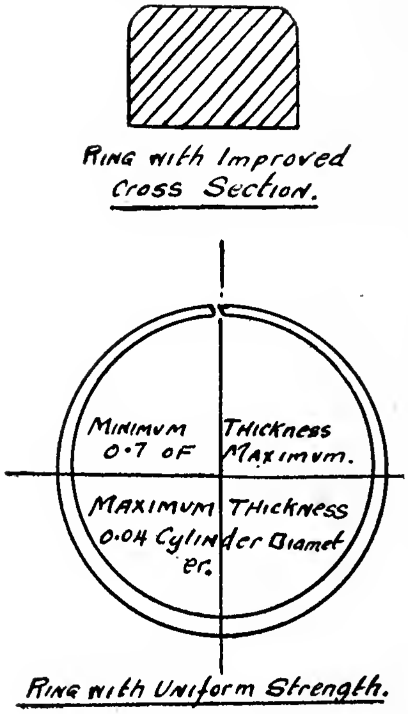

FIG. 5.

supply of oil is controlled by the steam pressure, consequently it is left to the engineer to "crack the throttle" on a down grade so as to maintain sufficient oil supply to the cylinder.

The methods of supplying oil to the cylinders vary. In some engines the oil is admitted to the steam pipes just previous to entering the valve, in others to the live steam valve passages themselves and in a few cases to the cylinders direct, at a point in the middle of the stroke and as near the top as possible. Some of the methods in use are:

(a)—One feed per steam chest, admitting the oil into the steam channel near the steam chest.

(b)—One feed per steam chest, admitting oil into the centre of the steam chamber.

(c)—Two feeds per steam chest, one near each admission point.

(d)—Three feeds per steam chest, one in the centre of the steam chamber, and one at each end near the admission ports, each point of delivery having an individual lubricator feed.

Methods of Lubrication.

The correct way would be directly to the top of the cylinders, as it has been found in three cases out of five that the most wear occurs at this point. It is all

the more necessary to select the best method of lubrication, because the quality and quantity of oil supplied to railroad engineers is standardized and strictly limited to a minimum allowance, according to the type of engine and class of work.

In the case of an engine having cylinders 21 inches diameter by 28 inches stroke, with driving wheels 75 inches diameter, travelling at an average speed of 50 miles per hour, the allowance might be, say, one pint of oil for every 75 miles. The foregoing dimensions and speed figure out at a piston travel of fully 1,000 feet per minute, so that unless all factors which influence the life of a piston ring are properly taken care of, the life of the piston ring may easily be shortened to an unsatisfactory minimum.

The amount of wear in rings varies from .06 inch to .19 inch for 10,000 to 80,000 miles, and the greatest wear occurrs opposite the split. Just what effect an eccentric ring, having uniform expansive pressure, would have on this wear has not been determined, as the other variables have been too great, but there is no doubt the wear would be much more uniform.

Effect of Superheat.

The effect of the high temperature of superheated steam is to weaken the cast iron, causing the rings to lose their spring. Experiments have shown that a superheat of 119 deg. F. is sufficient to decrease the strength 9 per cent., and when steel is heated to a maximum temperature of 400 to 650 deg. F. and stressed sufficient to create 1 per cent. distortion, its brittleness is increased about 33 per cent. Now, if we use a cast iron possessing characteristics somewhat resembling those of steel, which is stronger and therefore less liable to failure, are we not making an improvement in our piston rings?

The grade of oil used is necessarily important and with the moderate superheat used in this country, should show the following characteristics:

Flash point, 560 deg. F.

Burning point, 630 deg. F.

Cold test, 39 deg. F.

Spec. grav. at 60 deg. F., 25 degrees.

Saponifiable fats, 9.0.

Viscosity at 212 deg. F., 205 units.

With different degrees of superheat different oils must be used, i.e., for higher superheat, oil with a higher flash and burning point is required. A high superheat oil may be used for moderate and low superheat, but the cost would be a factor.

If the oil carbonizes, there is an excess of incrustation, which is equivalent to grit, as it causes abrasion. Then again, some tests have shown that excessive incrustation interferes with the ring springing up tight to the cylinder walls, and admits of a leakage of, some say, as much as 200 to 300 lbs. of water per hour.

Practical Points.

Some companies claim that they are getting their rings more uniformly lubricated by altering the section of the ring, as in sketch, Fig. 5, thus cutting off all sharp corners and allowing the oil to get under the ring instead of being scraped off ahead of the piston.

The best practice shows that the bushing must not vary out of round more than 1-16 inch, and the piston diameter must not vary more than ⅛ inch from the cylinder diameter. After the piston ring grooves in piston head have been worn 1-16 inch, a different sized ring is put in and, as the groove increases in size, the rings are increased by 1-16 in., until the original size has been exceeded by 3-16 inch, then the piston is scrapped.

Recently some engines were giving trouble with their rings making only about 300 miles before they had to be renewed. The pistons were changed and the rings made their average mileage.

NOBLEMAN MUNITIONS' WORKER.

SLOWLY, but surely, Britain is coming to realize that she must exert every ounce of her strength if she hopes to win out decisively over Prussian military preparedness. The formation of the coalition war cabinet, with David Lloyd George as war munition secretary, charged with providing the forces at the front with the necessary equipment in required quality and quantity, has brought about a new spirit, and the Britishers are beginning to see that not only the soldiers on the firing line, but the whole nation must work and work hard. The picture shows Lord Norbury, one of England's wealthiest noblemen, who has taken a job in an aeroplane factory as a fitter, both to do his share and by his example encourage others to go to work to do their share. Lord Norbury earns 7d (14 cents) per hour, and is here shown ringing in on an "International" time recorder in his suit of overalls.

LORD NORBURY AS A MUNITION'S WORKER "RINGING-IN" ON AN INTERNATIONAL TIME RECORDER.

Principles of Laying—Off Cylindrical Intersections--IV.

By J. W. Ross

The more or less special nature of the work involved in the making of sheet metal piping has caused many manufacturers to avoid this class of work, with the result that when a job has to be handled, there is frequently considerable unnecessary loss incurred through errors in laying off material. The examples treated by the writer of this article should form a valuable reference to many manufacturers on ordinary as well as special occasions.

CYLINDER INTERSECTION ON THE SIDE OF A LARGER CYLINDER.

THE two elevation views Figs. 29 and 30, and the perspective Fig. 28, shows a small pipe intersecting a larger one. The small pipe being placed on the side of the large one, in a manner so that one side of the small cylinder is tangent to the larger cylinder, while the other side intersects the cylinder. The axis or centre lines intersect each other in both views thus giving the true length of all lines parallel to each view.

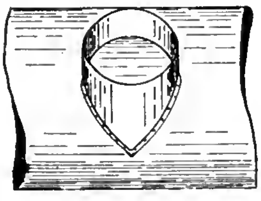

FIG. 28.

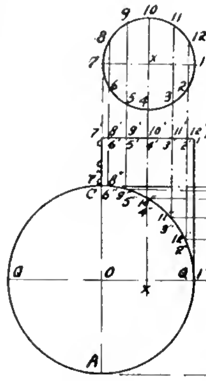

FIG. 29.

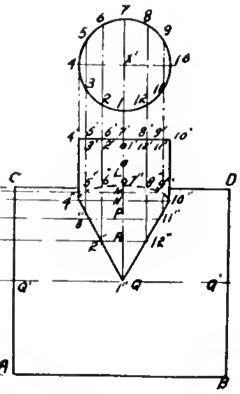

FIG. 30.

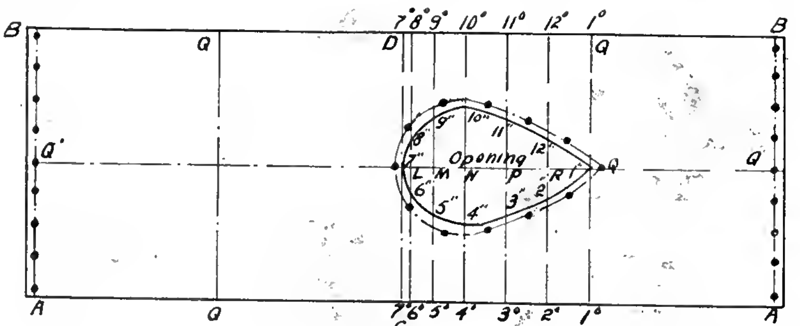

FIG. 32.

Construction.

With centre O and radius O A equal to 2 inches draw the neutral end view A Q C Q. Draw the horizontal line Q O Q. Bisect O Q at X. Raise the vertical axis or centre line X 10 at right angles to Q O Q. Parallel to this line draw the line 1^2 1^1 tangent to the circle A Q C Q. Also draw the parallel line 7^2 7^1 intersecting the circle at C^1. Measure off 7^2 7^1 equal to ½ inch and 1^2 1^1 equal to 1½ inches. Connect 7^1 to 1^1. This line is parallel to the line Q O Q. By this construction 7^1 1^2 equals 1 inch, of which 10^1 is the centre. Draw the plan view of the vertical cylinder, represented by the circle 1, 4, 7, 10. Divide into 12 equal spaces. Project these points down to the intersection of curve C Q. Project the horizontal Q O Q Fig. 29 over to Q^1 Q^1 Fig. 30. Make Q^1 Q^2 equal to 2¼ inches. Build up the elevation view A C D B around the line Q^1 Q^1. Bisect Q^1 Q^1 at Q. Erect the perpendicular Q 7. Project 7^1 1^1, Fig. 29, over to $4^1 10^1$, Fig. 30. Measure off 4^1, 7^1, 10^1, Fig. 30 equal to 7^1, 10^1, 1^1, Fig. 29. Draw the circle 1 4 7 10, Fig. 30, with Y^1 as centre and radius equal to half the neutral diameter of the vertical pipe. Divide into 12 equal spaces, number, and project these points down beyond C D. Draw horizontal projectors from Fig. 29 to the intersection of similar numbered vertical projectors in Fig. 30. Number these points in relation to the intersections. Connect these points, thus defining the mitre line as is shown in Fig. 30, by the points 1^2 2^2 3^2 4^2 5^2 6^2 7^2, etc. Locate the points L M N P Q R at the intersection of the horizontal lines with the centre line 7 Q. Fig. 30.

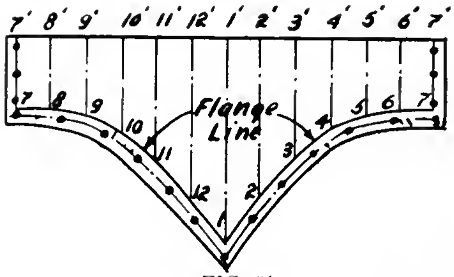

FIG. 31.

The Development of the Vertical Cylinder.

Measure off the stretchout 7^1 1^1 7^1, Fig. 31. Divide into 12 equal spaces. Project these points downwards. Number in relation to the position of the vertical seam. Transfer the element distances from either Figs. 29 or 30. An even

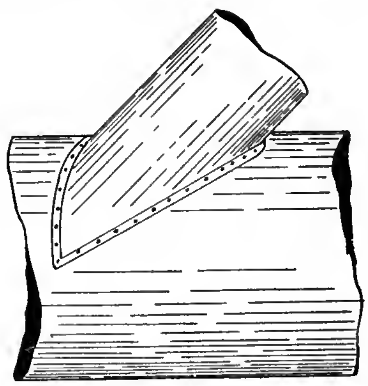

FIG. 33.

*Note: The reference letters and numerals in the text, i.e., G^2, 7^2, etc., correspond with those of the illustrations indicated as G", 7", etc.

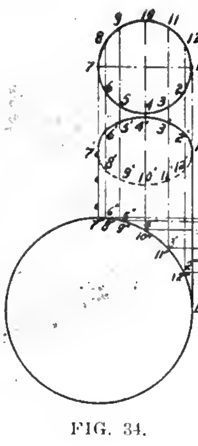

FIG. 34.

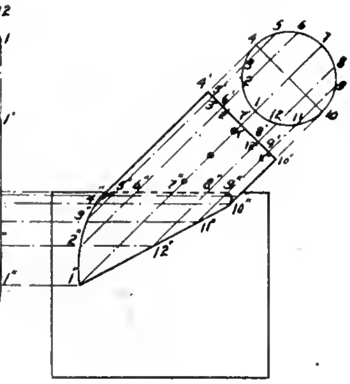

FIG. 35.

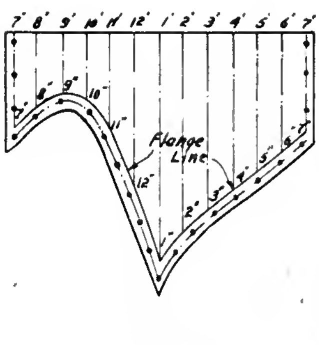

FIG. 36.

curve drawn through these points will define the flange line. Add the laps and draw in the rivet centres. Fig. 31 shows the complete templet.

Horizontal Cylinder Development.

Measure the stretchout, A C A, Fig. 32, equal to 3.14 times the diameter Q O Q, Fig. 29. Bisect A C A at C, erect the perpendicular C D. Take the length of the divisions—along the curve—7² 6¹ 6² 5² 5² 4², etc., Fig. 29. Transfer to 7° 6° 6° 5° 5° 4°, etc., Fig. 32. Raise perpendiculars. Bisect B A at the point Q. Draw the centre line Q Q. Locate the points L M N P Q R, Fig. 32, in relation to their positions in Fig. 30. Transfer from Fig. 30 the distances L 6², L 8², M 5², M 9², N 4² N 10², etc., to Fig. 32, as L 6², L 8², M 5², M 9², etc. A line drawn taking in all these points will define the opening of this cylinder. Draw in the rivet line. Add the laps to the seams B A. Fig. 32 shows the complete templet.

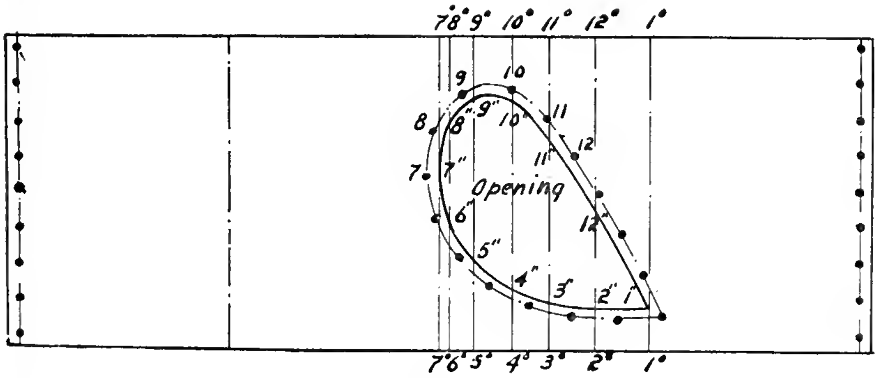

FIG. 37.

Inclined Intersection of 45 Degrees.

The perspective, Fig. 33, and the elevations, Figs. 34 and 35, show a similar problem to the preceding one. The difference being that in one of the views the pipe is inclined to 45 degrees to the horizontal pipe.

From the experience derived from the study of the previous problems, the student ought now to be able to construct this problem and develop the patterns. Your attention is drawn to the peculiar shape of the mitre line in Fig. 35, the pattern in Fig. 36, and of the opening, Fig. 37.

NEW PRACTICE IN UPSETTING.

THE Ford Motor Co. has placed orders for upsetting machines, the aggregate value of which will approximate $350,000, says the Iron Age. This equipment is to be installed in a new building to be erected at once, the extension of capacity being occasioned by the development of a new method of upsetting circular pieces having an open centre, such as gear blanks, collars and other forgings ordinarily made heretofore on hammers. It is not long since that it was impossible to secure such pieces with the central hole punched through, all of this metal having to be drilled out. More recently this practice has improved, and the machining required has been limited to drilling the hole to size, although even in this case considerable metal has had to be removed.

Process Features.

The practice which is being developed by the Ford Motor Co. for pieces of this character, not only provides for forging the hole in the centre within such limits of size as to require only a finishing cut in the machine shop, but results in the piece being formed without any waste of material. Even the flash is eliminated. While the process in general has not been sufficiently completed to warrant detailed description, it consists of upsetting pieces of the general form described, from bar stock of the same diameter as the central hole in the finished forging.

The work is done in two or three operations, depending upon the relation of the finished outside diameter of the forging to the diameter of the stock. The diameter of the stock may be safely increased 1½ times. In the first operation, the end of the stock is pierced and spread; in the second operation the upset end of the stock is partly formed in a way which prepares for the third and finishing operation the exact amount of metal required, so that the piece finishes without any flash to be trimmed in a final operation. The third operation involves the simple stripping of the forging from the stock, the punching removed from the centre of the forging remaining on the bar and being worked up into the next piece, so that there is absolutely no waste of metal.

On some pieces it is possible to combine the first spreading operation with the stripping operation which finishes the preceding piece. At the Ford plant an interesting revision of machining operations will follow as a result of this new forging practice.

CANADIAN GOODS NEEDED IN RUSSIA.

RUSSIAN banks are interested greatly in Canada's determination to enter the Russian market, according to a further report received by the Department of Trade and Commerce, Ottawa, from C. F. Just, special Canadian Trade Commissioner. Mr. Just gives an extended list of articles which could be made the basis of a large trade between this country and Russia. He again emphasizes the desirability of the establishment of agencies in Russia, especially in regard to the trade in agricultural and other machinery, the United States manufacturers having erected works which, when in full working order, will take care of one-sixth of the total annual requirements of the country. Russia needs the light type of agricultural machinery, and the trade, says the commissioner, is capable of indefinite extension. A Canadian forwarding agency in Russia is recommended. Mr. Just states that the forwarding business has been in German hands, and that "it has been attended with disagreeable surprises since the war began."

NON-RUSTING OR STAINLESS STEEL.

THE fact was lately mentioned in a United States consular report from Sheffield, England, that a firm in that city had introduced a steel which is claimed to be non-rusting, unstainable and untarnishable. The steel is especially adapted for table cutlery, as the original polish is maintained after use, even when brought in contact with most acid foods. It is an interesting fact that the steel was not made with a view to producing cutlery, however. The investigator was endeavoring to produce a steel for pump rods used in collieries, where a damp atmosphere had to be resisted. The application of the steel to cutlery was but a natural sequence, and no doubt a multitude of other uses will be found for it. In a tempered condition the steel has a maximum strength of 50 to 55 tons per square inch, and elongation of 20 per cent., and a reduction of area approaching 60 per cent. In the hardened condition the tensile strength is raised to about 100 tons. It is claimed that the steel retains a keen edge, much the same as the best double-shear steel. This stainless steel is made by Messrs. Thomas Firth & Son, Ltd., of Sheffield, England. Obviously there are many situations where a non-tarnishable steel would be much more satisfactory than the present steels.

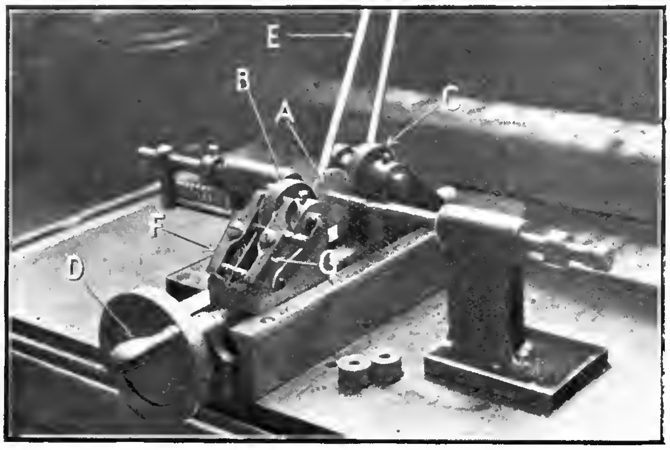
PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

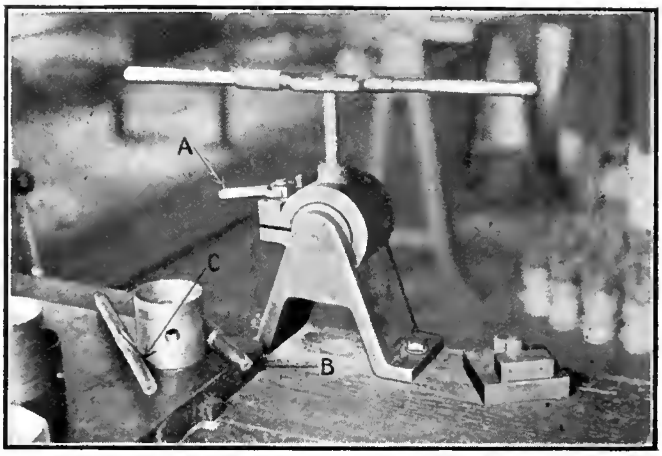
KNURLING SMALL BRASS GEAR TEETH.

By Avery E. Granville

AN unusual method of forming gear teeth is here shown. The small brass gears are used on a talking machine, and run as smooth as any cut gear possibly could. The brass blank on which the teeth are to be formed, is placed at A between the two knurls B and C, which are really master gears. These knurls are fed in to the blank by turning the handwheel D which operates a right and left-hand screw, so that the knurls are fed to the blank simultaneously from opposite sides, preventing undue strain on the spindle of the blank. Power is obtained through the belt E which drives the rear knurl. The jaws F and G are padded on the ends which press against the front knurl, and act as a sort of brake, preventing chatter or backlash. The teeth are formed much quicker than is possible in any other way, except in a case where they may be all cut at once in a punch press die. The burr left on the edges of the gear by the knurls is easily trimmed off in a small lathe.



KNURLING BRASS GEAR TEETH.



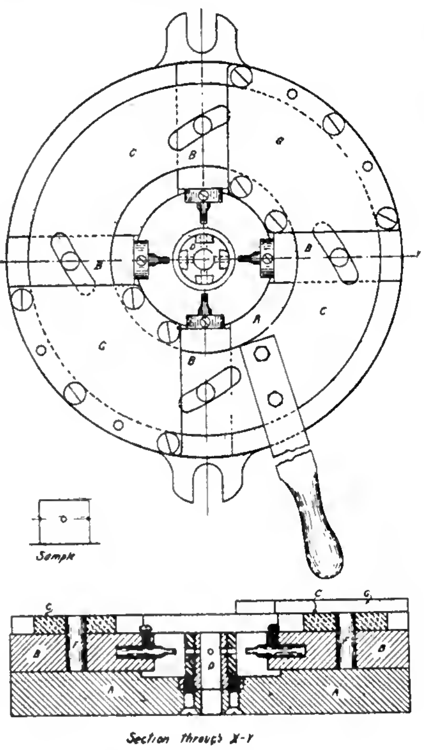
PISTON LINE-REAMING JIG.

RADIAL HAND PUNCH.

By S. Simpson.

THIS device was gotten out for the purpose of punching four holes simultaneously in small cylindrical shells or cups, see J in the illustration which also shows plan and sectional elevation of fixture. Block A is a casting having suitable lugs provided for bolting to a bench. Four radial slots are made to act as guides for the punch holders B, which are square section cold rolled steel. In the top face of casting A, a wide, shallow groove is turned to receive the steel ring C, which forms a cam plate. The bottom of the groove is made to just clear the upper side of punchholders B, so that cam plate C acts as a retainer for these pieces. Suitable cam slots are made in C to engage with hardened steel pins F carried by punchholders B.

Two segmental plates G are each secured to the main casting A by five countersunk machine screws, and are adjusted so that cam plate C may be



RADIAL HAND PUNCH.

oscillated by hand lever H, thus causing the cam slots to act on pins F and force the punch holders toward the centre of block A. Die block D is of cast iron and is fixed in a recess by screws from below. The dies proper are made of hardened steel and are dovetailed into block D, through the centre of which a hole is made to allow punchings to fall through. The steel punches are held in holders B by small screws as shown. This style of fixture worked well when constructed for two and also for six punches.

PISTON LINE-REAMING JIG.

By A. E. G.

MOTOR pistons, that have the wrist-pin hole drilled and reamed in a turret lathe, must have the hole hand-reamed afterward, in order to keep the size accurate. A very good holding jig for the hand operation is shown in the illustration. The clamping band is operated by means of a bolt and nut, the latter being turned by the small lever A.

When first putting in the piston, it is located in line with the guide bushing by means of the locating plug B, which is tapered on the end to facilitate insertion. The reamers used are cut left-hand spiral so as not to bind or feed in too fast. They are also piloted as shown at C, the pilot fitting into a bushing in the bottom of the clamping ring. Two reamers are run through each hole, one to accurately line it up, and the other to bring it to exact size.

ADJUSTABLE DEVICE FOR HAND PUNCH PRESS.

By H. Womersley.

IN the construction of large steam turbines many operations and adjustments are necessary which vary considerably

from what has been developed in the building of ordinary steam engines.

The thousands of blades which enter into the construction of a turbine must be securely fastened in place, and many different systems of doing so are in use. Some of these necessitate the use of bands to retain the blades in position. These bands require to have holes punched so that they may be slipped over the blades into position. In the case of a turbine of 12,000 horse power, there were forty rows of blades on the rotor or revolving member, and the same number on the casing which surrounds the rotor. As it required on an average six bands to fasten one row of blades there were almost 500 bands required for this particular machine. These forty rows of blades were located on different diameters of the rotor and casing, causing a variation in the pitch of the holes in the bands.

Object of Device.

The device shown in Fig. 1, was made up so that the holes in the bands could be punched quickly and accurately to any required pitch. Adjusting shaft A is supported in two bearings B and C. Collars are provided on both sides of B to prevent any endwise movement of A. Block D is tapped to make a good fit on shaft A, and is provided with a pin on the underside to slide in a slot on bed plate. Frame member E is pivoted on top of block D and frame member F is pivoted on top of bearing B. Spacing strips G are now fastened to frame members E and F. These strips must be exactly alike, and the holes in the frame members to which they are fastened must be laid off on a perfectly straight line, and corresponding holes must be accurately spaced from centre of pivots in ends of frame members. A hand wheel H is provided, by turning which block D may be moved to any desired position on shaft A.

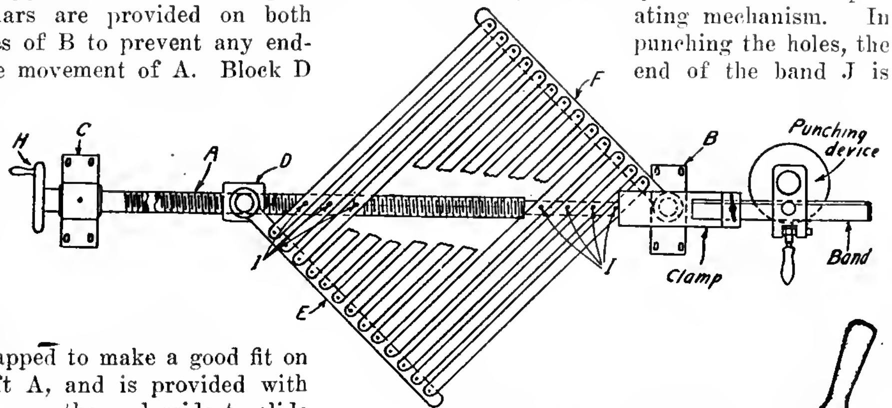


FIG. 1. ADJUSTABLE DEVICE FOR HAND PUNCH PRESS.

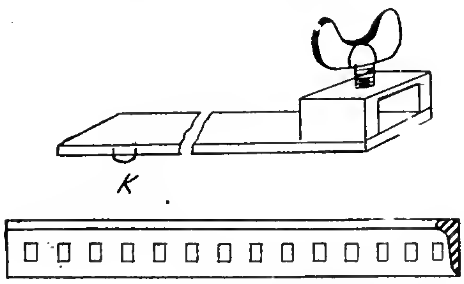

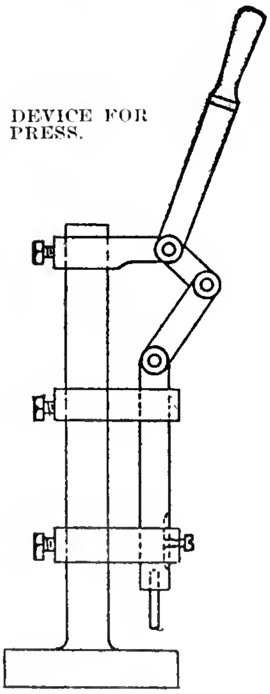

FIG. 2. PUNCHING MACHINE, CLAMP, AND BAND.

Method of Operation.

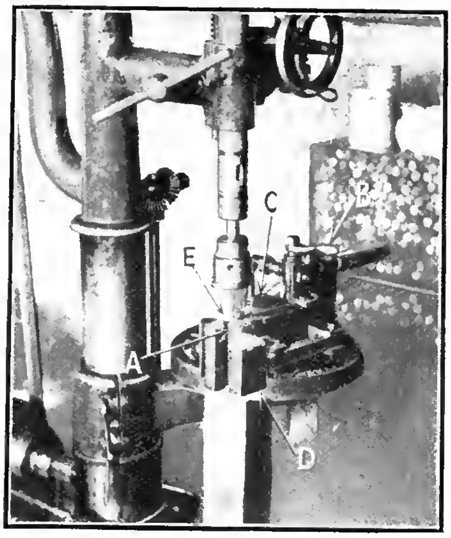
When the apparatus is assembled and mounted on a suitable bench, block D is located in a convenient position and a straight edge securely fastened to pivots D and B so that the jig holes I in strips G may be located on a straight line which extends from centre of pivot B to centre of pivot D and which is parallel with shaft A in a vertical plane.

When block D is moved in either direction on shaft A, the strips G and therefore the jigholes I will move closer together or farther apart, thus allowing the pitch of jig holes I to be adjusted to any required pitch within the capacity of the frame.

By making shaft A long enough, any number of jig holes may be provided.

The punching machine Fig. 2 is made of a piece of cold rolled shaft screwed into a cast iron base for fastening to the bench. The punching spindle is carried in two guides made of flat bar stock and fixed in position by set screws. A toggle joint lever provides suitable operating mechanism. In punching the holes, the end of the band J is secured by wing nut in clamp Fig. 1. Pin K on the underside of clamp is placed in jig hole next pivot B, and the first hole punched, after which pin K is moved to next jig hole, and so on.

The spacing device is simple and when accurately made gives very good service. Many opportunities may happen when a device of this nature will be found very useful in different lines of manufacture.



STAY BOLT DRILLING FIXTURE.

STAYBOLT DRILLING FIXTURE.

By G. Edwards.

ONE of our big railroad shops uses the air clamping fixture shown, to hold staybolts while drilling the tell-tale holes. The staybolt is placed at A and the air is turned on by means of lever B. This admits air to the cylinder C and causes the jaw D to move in and lock the staybolt into the V-groove in which it rests. A drill bushing is carried in the bracket E to guide the drill. Connection is made to the shop air supply through a short piece of hose. When not in use, the device is easily removed, leaving the table clear for other work.

The Steel Company of Canada, Hamilton, Ont., has been making remarkable headway in shell-making, according to official advices. Orders obtained by the Shell Committee called for something like 650,000 shells, and out of the 605,000 delivered to date, rejections only amount to the insignificant number of 62, making an almost perfect showing for the plant. Why the officials are particularly pleased with the result is that it was only in February that they started on the erection of the plant which is being used for the manufacture of shells, and the entire plant is manned by the company's own men, who have turned from their ordinary work to the special lines that are now being required.

ELECTRIC POWER IN MANUFACTURING ESTABLISHMENTS.

By H. Womersley.

THE progress of electric driving in machine shops and factories has been so gradual and persistent that many persons never stop to think how widely it has been adopted. Instances of reverting to former mechanical methods of transmission, are extremely rare, and a brief resume of the principal factors which have influenced the development of electrical power may serve to remind many of us of conditions which previously existed and which would not now be tolerated in any progressive establishment.

Increased Transmission Efficiency.

This is generally the first point to be considered, but it is by no means the most important, as the cost of power in manufacturing is rarely more than 1 to 3 per cent. of the cost of the finished product, the expenditure for labor alone being usually many times greater. There is a practical limit however to the power that can be transmitted by belting from a single unit. On the other hand an engine or turbine may be directly connected to an electric generator producing 10,000 horsepower or more, the whole of which can be readily transmitted and sub-divided, also combined with the output of other generators. Thus the power of the individual prime mover can be increased to almost any extent provided it is utilized electrically. Enormous pumps or air compressors are almost the only machines except electric generators that are adapted to be driven by engines of 5,000 horsepower or more. For thousands of other power applications, the size of prime movers, including steam and gas engines as well as steam and hydraulic turbines, is practically limited to units of moderate size if dependent upon mechanical transmission, and distribution by belting or gearing. Of course these statements do not apply to steam vessels, in which many thousands horsepower are often applied to a single propellor, this being a case of direct connection. They do apply, however, to the electric-railway service, for which one very large engine in a power house may replace many steam locomotives. The advantage of large units compared with small ones include saving in first cost, floor space, fuel and attendance.

Cost of Buildings.

Heavy overhead shafting is not required for the electric drive, hence the buildings may be made lighter and cheaper in construction, as they do not have to carry the large extra weight. Moreover it is not necessary, as with long lines of shafting, to take special precautions in order to avoid any settling which would throw them out of alignment and cause serious friction losses, vibration, etc.

Cost of Equipment.

The relative expense of equipping a factory with electric motors or with belting and shafting is not usually much if any greater for the former, even if we do not consider the lower cost of the lighter building construction.

Clear Head Room.

The elmination of overhead belting and shafting by the use of motors gives a clear head-room, which enables overhead cranes to be used freely; a fact which results in great saving of time and labor in the bringing of the work to the tools or removing finished pieces. The clear head-room also gives better illumination and ventilation. In fact the saving in cost of proper illumination may be very considerable because general instead of local lighting may be obtained, whether natural or artificial.

Convenience for Detached Buildings.

The electrical method enables power to be supplied easily and economically to detached buildings or sections, which is not possible with belt or steam transmission; therefore, the buildings, like the machinery within them, can be located for general convenience, and not with special regard to supplying them with power. This sub-division of an industrial establishment into a series of detached buildings is an almost absolute safeguard against total destruction by fire; and is thus a practical guarantee of continued earning capacity. If electric power were not employed, it would be necessary to have very extended belting and shafting connections, involving great losses and extra heavy wall construction, or a number of small power plants with a larger force of men considerably less economical in operation than one central power house.

Freedom for Growth.

For similar reasons, with electric drive it is a simple matter to extend a building, or add another in any direction, whereas shafting must be installed originally large enough to allow for extension; or else it must be replaced later; in which case the operation of the existing line shafts would be interfered with.

Increased Output.

Owing to its many advantages, but especially on account of clear head-room for crane service and convenient speed control, it is found that the output of manufacturing establishments is in most cases materially increased or the running expenses decreased by the introduction of electric drive. An added output of 20 or 30 per cent. is often obtained from the same plant, which in itself is sufficient to make the difference between profit and loss in carrying on a manufacturing business.

Overtime Work.

Also work on holidays or during strikes, may be carried on conveniently and economically with a portion of the machinery or even with a single tool, because a small engine and generator may be run to supply the electric power. On the other hand, the main engine and the whole or a large part of the shafting and belting would have to be operated in order to supply the power by the ordinary mechanical transmission.

Noise.

The elimination of noise is a desirable feature of electric driving. Line shafts with rumbling gears and slapping belts, with their attendant dangers and constant demands for attention and upkeep being entirely dispensed with when electric drive is adopted.

HOW I FELT NEAR A DANGEROUS BOILER.

By W. F. S.

I HAD a sort of sneaking suspicion that the boiler was going to blow up. Chris, the fireman, had allowed the water to go down out of sight in the water-glass and below the gauge cocks. He said he hadn't seen water for an hour, and, growing frightened, he came to me for succor.

My remedy was to draw the fire and shut down the plant, which we did right hastily.

While performing this operation I moved about as nimbly as Chas. Chaplin, I'll wager. Was on my tip-toes most of the time, my idea being that if she blew up I wanted to go up with her as easily

as possible. You always feel that there will be less concussion when on tip-toe.

I suppose the feeling of the soldier is much the same when he sees enormous cannon staring him in the face, and is told that he must charge against them. Hence, I often wonder if soldiers run on their toes. They all must be possessed with the maybe-it-will-happen, and maybe-it-will-not feeling.

After all is over the joy of living is intensified for a few moments; but soon the **big** boss comes along, and what he says sort of spoils the story. I shall therefore close. However, the feeling is unique.

CONCERNING BELT SLIPPAGE.

By R. McLaren.

AFTER reading N. G. Near's article in Canadian Machinery, July 22, I am still unconvinced that a slipping belt necessarily means fuel waste. Mr. Near uses as an illustration a hoisting engine, holding stationary a 33,000 pounds weight and states that it takes no more power to raise the latter than to hold it stationary.

We will assume that the weight is suspended from the drum by a cable and that the cable slips on the drum, the tension being adjustable in a manner similar to the brake band. We will assume also that the drum has a radius of 1 ft. and that it turns at the rate of 100 r.p.m. The power required to hold the weight stationary would be $2 \times 1 \times 3.1416 \times 100 \times 33000 = 628.32$ h.p. How then would he cause the weight to rise?

I would do it by running the engine faster, or by increasing the tension, and I think Mr. Near will admit that running the engine faster will require more steam. Anyway the firemen will admit it. We have already found that reducing the tension reduces the pressure on the scales, and therefore the steam consumption. Conversely if we increase the tension and reduce the slip, more steam will be required to maintain the speed of the drum at 100 r.p.m. Does he claim that it is as easy to climb a stair as to walk along a level floor?

He also cites the gas engine to prove his claim, but we are evidently not congenial spirits for here again I cannot agree with him. To be sure the slip occurs when the tension is greatest, but it simply means that the speed of the flywheel is increased, that is, energy is stored up in the wheeel to be given out again.

As a matter of fact, if the engine is underloaded, enough energy can be stored up in the wheel to carry the load over several cycles. Of course, in that case there is waste of fuel, but it is due to excessive cooling of the cylinder walls and is not the waste to which N.G.N. refers.

Evidently belt slip does not necessarily mean fuel waste.

THE MIRROR OF PRACTICE.

By N. G. Near.

YOUR face is dirty. Somebody has told you that it is dirty and you half believe it, but anyway, to convince yourself you look into a mirror and there, sure enough, you see the image of the dirt. Now, what do you do to remove the dirt? Do you wash and polish the mirror? Doing that would only make the presence of the dirt more evident. You can't wash your image and get rid of the dirt. You must wash your face. It is always best to apply the preventive at the source. No matter what you do to the effect, the cause remains unaltered.

In power plant practice, therefore, you can chip scale until doomsday, and it will keep right on forming in the boilers. To keep it out, the water must be treated, not the scale.

Black smoke is pouring out of your stacks. You don't make it white by adding smoke of a different color. You stop the smoke by burning the coal properly.

Your bearings run hot all the time. It would be foolish to keep on re-babbitting without applying oil.

The engine knocks or the turbine rattles. You don't build a muffler around the engine to stop the noise. You stop the noise at the source.

When things go wrong in general, therefore, don't blame the things themselves. Don't always blame the owner, the manager or the superintendent. Maybe **you** are the source yourself.

The image you see in the mirror of practice may be a reflection of yourself, so cleanse yourself.

MAKE STEAM PIPES A TRIFLE SHORT.

By N. Y. C.

A METHOD for dimensioning lengths of steam pipes that may be romoved easily in case repairs are needed is now being used by an Eastern designer holding a responsible position with a well-known engineering company.

Usually, where a straight steam pipe line is laid in an average boiler room, little if any allowance is made for pipe expansion when under steam. The expansion is permitted to take care of itself which often is the cause of creating dangerous stresses in the pipes and auxiliary connections.

To overcome these stresses in places where bends are to be avoided as much as possible, this designer makes the pipe initially too short—about 1-10 inch for every ten feet, or one inch per hundred feet. The longitudinal stresses are therefore in the pipe when cold—in tension. And should it be desired to take a length out, a bolted flange-pipe may be dropped out easily.

When under steam, the shortage is taken up by expansion and it is computed that there are no longitudinal stresses in the pipe whatever. This is as it should be for insurance of safety.

BRASS MELTING QUERY ANSWER.

FROM the information given in the "Brass Melting Query" which appeared in a recent issue, it is somewhat difficult to give a very intelligent answer as it is not stated whether the metals are new or scrap. From the facts at hand, however, it would seem that some of the metals have an excess of dross or slag.

As regards using charcoal as a flux, I might say that charcoal is used as a covering only to protect the metal from the air, and has no other effect on the metal. Salt is a great help in melting brass, but should be used at the proper time, that is, just as the first metal begins to melt. A handful of salt to the ordinary crucible is sufficient.

The best means to overcome the stated difficulty is to melt meal in crucibles and pour it into ingot moulds, using plaster of Paris for a flux. This material when so used dissolves all the foreign matter that may be present in the metals in the form of sand, oxide or slag. It forms a very liquid slag and has no bad effect on the crucible like some fluxes but rather keeps it clean. About 5 lbs. of plaster of Paris to 50 lbs. of metal should give good results. It should be mixed with the metal as it is charged into your crucible.

Melt the metal in the usual manner, and, if the slag is not fluid enough at the conclusion of the melt, add more plaster of Paris. Do not attempt to skim metal when it is ready, but pour into ingot moulds. The slag will all rise to the top and when cool, the slag of the plaster of Paris can be easily detached by a few blows of a hammer. Remelting will produce good castings.

It is not practical to melt metal as for iron as it would be too much exposed to the air and would be sure to absorb some injurious gases.

The Steel Company of Canada, Hamilton, Ont., has made arrangements to increase its open-hearth steel capacity to take care of the large orders it has received from England and from the Canadian Car & Foundry Co.

CONTEMPORARY WAR ARTICLES

Embracing Information and Data Drawn from a Variety of Sources Relative to and Arising from the Prosecution of this Many-Sided European War

THE YEAR'S WORK AT SEA.

WHEN, in 1804, Nelson had been cruising for fourteen months off Toulon, hoping and praying that the French fleet would come out and give him battle, says the naval correspondent of the Globe, the City of London made the egregious mistake of sending him a vote of thanks for—to quote Southey—"his skill and perseverance in blockading that port so as to prevent the French from putting to sea."

Nelson, already sore because the city had omitted its customary thanks after the destruction of the Danish fleet at Copenhagen, was not slow to seize the advantage which this communication offered him. "I beg to inform your Lordship," he wrote to the Lord Mayor, "that the port of Toulon has never been blockaded by me; quite the reverse. Every opportunity has been offered to the enemy to put to sea, for it is there that we hope to realize the hopes and expectations of our country."

The error of the City Fathers was not a very heinous one, for, after all, there is little difference from the enemy's point of view between remaining in port under compulsion and coming out to destruction; in either case the ocean highways are closed to him and free to his superiors. That was the case of the French and Spanish navies during the 29 months' wait of the British fleet that led up at last to Trafalgar, and it is the case of the German fleet to-day.

Superiority in Guns.

A year of war has passed without any serious attempt on the part of the enemy either to challenge our command of the sea or to diminish the margin of superiority by which we hold it; and as far as the so-called high sea fleet is concerned it is not easy to see what it could have done of greater benefit to its country than to keep safely out of harm's way. We do not know what the measure of Sir John Jellicoe's superiority may be in ships, but it is considerable; and it is enhanced to a great degree by the folly of Krupp commercialism, which bound the German navy down to the 12-inch gun while we were mounting the 13.5 and the 15-inch.

The first year of hostilities has, however, forced upon the notice of the world a factor of far greater importance than ships and guns. The German seaman has proved himself a man not lacking in courage. Whether we take the ships that went down off the Falklands, or the battering which the stranded Emden stood before a seaman swarmed up her mast and tore down the colors that were nailed to it, or the officer of U-18 who chose to sink his ship and himself with her rather than she should fall into our hands—these incidents are evidence of a courage that must compel our respect. At the same time, there is a canker gnawing at the spirit and efficiency of the German fleet that must tell increasingly in our favor as time goes on.

German Sea-Sense.

On August 18 last year the Admiralty reported that there had been "desultory fighting" in the North Sea. What it amounted to we have never been told; but it is the only occasion so far on which British and German forces have been in conflict in those waters without the hostile force being totally destroyed or badly mauled, or else running full pelt for its harbors at the first sight of a British ensign. It is true that in most of these meetings the balance of strength has been on our side—which is but a testimony to the efficiency of our own and the inefficiency of the German staff.

Count Reventlow has told us some pretty tales about the Dogger Bank action of January 24; and this, as it happens, affords us a very useful illustration of the subject of this article. The Blucher, he tells us, "ought not to have been brought into the battle at all." That is obvious to the most casual of arm-chair strategists; but to what degree has the confidence of the German navy in its rulers been increased by this act of sheer, criminal folly? The ex-lieutenant also points out, correctly enough, that the British ships had the advantage in gun calibre; but he surely does not forget that the German people and the German navy have been assured again and again by Von Tirpitz himself that the Krupp 11-in. was better than our 12-in., and their 12-in. at least as good as our 13.5. In this matter, again, surely there must be some doubts arising in the fleet as to the sea-sense of its managers.

It is not necessarily a disgrace to flee before a superior force, though it is not a habit that has been cultivated by our own fleet in this war or any other; but what do the German Puggs (no disrespect) talk about when the day's work is done? Is it about the "raid" on Yarmouth in November, when a squadron of battle and armored cruisers fled so precipitately before a few of our light cruisers (which they could have eaten) that one of them careered into a German mine-field and sank? Is it about the plucky fight which the 22,640-ton Goeben and the 4,480-ton Breslau put up against the mighty Gloucester, whose entire broadside weighs less than a half of a single shell from a Goeben gun? Or is it about the victories that the despised Russians have won in the only two stand-up fights that have so far occurred in the Baltic?

It is possible, no doubt, to feed up the German public with stories about the Tiger and similar "incidents"; but the seaman knows—he was there, and he knows that his government is backing up his poor best with lies. Unless he is in a submarine he knows he has never seen a British warship but to run away from it. He knows that, in four set scraps in the North Sea, eleven German cruisers and torpedo-craft have been sunk at a cost to us of an armed trawler. He knows that it is risking almost certain destruction to venture fifty miles beyond the limits of his mine-fields.

Good Gunnery Means Good Nerves.

Count Reventlow tells us that it has always been manifest that the German ships shoot better than the British, yet one whole squadron bombarded Yarmouth without even hitting the beach, while another fired several concentrated broadsides at a 500-ton destroyer and fled with a casualty list of one killed and eight wounded to its credit. German gunnery is not underrated in the British Navy. It is admittedly good, but it goes to pieces when the other ships—our ships—begin to hit back. This is the natural corollary of the usual roles occupied by our ships and the German.

Good gunnery requires good nerves, and to be in a fleeing ship with no object in view but to get safely home with a sound skin and a whole vessel is not conducive to steady nerves. Stern, close fighting, whenever possible, will always develop and emphasize the difference between our long-service seamen and the pressed three-year men who form the bulk of Germany's naval personnel.

To sum up—The moral ascendancy which our fleet has established in the first year's war is bound to increase as time goes on, for good seamen are not made by constantly shirking action, however much the shirking may be justified on other grounds. Of our own fleet little need be said. When we repeat Mr. Balfour's trenchant summary that "no fleet could have done more" we have said enough, save only one thing. There

is no greater augury for the future than the feelings that are entertained for Sir John Jellicoe by every officer and man under his command. It is doubtful if Nelson himself ever inspired more confidence and affection.

WAR AND INVENTION.

NOW that the names of those who are to be associated with Lord Fisher in the work of the new Inventions Board are announced it is clear that a serious effort is to be made to call in the aid of science to the more vigorous prosecution of the war at sea. It is true that apart from Lord Fisher there are no practical seamen on the board but, doubtless, the officials of the new department will include those with sea-going experience, so that whenever an invention comes up for consideration the arduous conditions of sea service may be in mind. It is common knowledge that devices which may suit laboratory conditions would be of no avail under the stress of actual service. On the scientific side the Board and the Consultative Panel constitute a strong body. The Central Committee will consist of:

Lord Fisher of Kilverstone, G.C.B., O.M. (president).
Sir J. J. Thomson, O.M., F.R.S.
Hon. Sir C. A. Parsons, K.C.B., F.R.S.
G. T. Beilby, Esq., F.R.S.

The Consulting Panel will comprise the following list, which will be added to from time to time as necessary:

Professor H. B. Baker, F.R.S.
Professor W. G. Braggs, F.R.S.
Professor H. C. H. Carpenter.
Sir William Crookes, O.M., F.R.S.
W. Duddell, Esq., F.R.S.
Professor Percy Frankland, F.R.S.
Professor Bertram Hopkinson, F.R.S.
Sir Oliver Lodge, F.R.S.
Professor W. J. Pope, F.R.S.
Sir Ernest Rutherford, F.R.S.
G. Gerald Stoney, Esq., F.R.S.
Professor the Hon. R. J. Strutt, F.R.S.

Stimulation of Research.

It is a list which may well hearten inventors whose aspirations have been chilled by official indifference, and whose genius has been allowed to stagnate for want of Government appreciation. The knowledge that future efforts in the field of invention are to be judged by such a tribunal should give a stimulus to research, from which important results may be expected. All branches of science with a leaven of industry, are represented on the new body. Electricians and physicists, engineers and inventors, professors and business men, all these are included. The Royal Society, Britain's premier scientific body, which has intimated its willingness to co-operate in the work, has furnished the majority of the committee and consultants, and it may be taken for granted that in this new body the best that the nation can furnish on the scientific side has been organized for the needs of the war as far as these may be served by new inventions.

One Urgent Need.

There are, of course, many problems in connection with the operation of ships of war, and their use as fighting machines, which remain to be solved, but the great problem of the moment is to find the real answer to the submarine, which undoubtedly threatens until the true answer is given, to become in future years the dominant type of warship. Already it is evident that it enables the attack to be delivered by the weaker power, and the new application of such vessels as commerce destroyers has indicated what might conceivably be accomplished by a great fleet of submarines.

It will be many years before the submarine reaches a position when it will be capable of effecting a real blockade of a considerable coast line, and long before that time there is no doubt that the real reply to the underwater fighting ship will have been found. It is important that Great Britain should find it. Already the somewhat crude methods which have been devised for checking the offensive power of the submarine have achieved much, but now that science has been definitely called in to aid the work it may not be long before the submarine is robbed of much of its fighting value.

If special attention has been directed to this question it is because its importance to a nation which must maintain the command of the sea is vital. There are, however, many other directions in which invention may find scope under the encouraging wing of the new board. Questions of ship propulsion, problems of naval ordnance, wireless communication, fire control—all these and many other questions are still far from being settled. The design and equipment of warships is never fixed for more than the shortest period: a single invention may revolutionize the whole science of naval warfare, the discovery of a new alloy may profoundly affect ship design.

There can be no finality in the contest of brains and money which up to the present time have maintained for Great Britain the sovereignty of the seas, nor must there be any truce, until wars shall cease, in the striving to assure to our country a navy which in ships, men and equipment will be superior to all others. It should be the object of the Inventions Board to contribute to this end, and the names of those associated with it are a guarantee that all that science, backed by engineering, can compass will be thrown into the national scale.

ENTHUSIASM.

ENTHUSIASM is the emblem of energy, not an epitaph of ended effort. Enthusiasm is business itch. Enthusiasm tells whether you are in a class or outclassed. Enthusiasm is energy "on the job."

Enthusiasm predicts your position tomorrow. The man that lacks enthusiasm has mud in his mental make-up. His place is in history. If you lack enthusiasm get out of the way, and let some fellow run that can show speed.

Enthusiasm is what gets you home from third—the power that compels you to stick in the home stretch. Enthusiasm is the zeal that puts zero in competition. Cash can buy, but it takes enthusiasm to sell.

One result-getter, one optimist, one enthusiastic, live wire, can do more to ginger up an organization than ten thousand dollars in additional salaries.

Self-reliance, self-confidence, hope, expectations, are some of the pillars of man's prosperity.

The despondent dub, the hopeless human, the forlorn fellow is sometimes tolerated on the payroll out of deference to those who are dependent upon him. It would be eminently cheaper, decidedly better, to pension this pessimistic parasite.

Then, there is the "old governor"—the so-called "conservative," the man who officially opposes everything. He is a candidate for respectable retirement, or for impeachment.

To-day it's go ahead or go behind—keep up or get off the trail. To-day it's the survival of successful men. To-day we hold the funeral for the flabby, the infirm in intellect, the groggy grouch.

Every big battle is first lost, then won by an enthusiast.

Enthusiasm is the biggest word in business to-day.—Silent Partner Magazine.

The efficient man is he who analyzes himself, striving continually toward an ideal—a standard—which embodies ultimate perfection. He is not satisfied with being adept in a few things, but must be proficient in all. He realizes that the underlying purpose of life is the formation of character, and so far as he succeeds or fails in this respect, the measure of his success lies. Therein, the lives of many of us fall short, for it is better to have aimed at a star and failed to touch the mark than neve rto have aimed at all.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

NEW PRODUCTION BASIS FOR COLD-SAWING.

THE present demand for a very much higher speed in cold-sawing than has been prevalent heretofore has been the prime incentive in the perfection of new loading tables for multiple bar cutting, by the Earle Gear and Machine Co., Wayne Junction, Philadelphia, Pa. The demand originated from shrapnel makers, whose shops were not equipped with automatic screw machinery.

The steel used in shrapnel manufacture, as called for in the specifications of the Canadian Shell Committee, are as follows:—Carbon, .45 to .55; phosphorous, .03; sulphur, .14; manganese, .60 to .80.

This constitutes quite a difficult metal for rapid cutting off, but that on which the tests were made at the plant of the Earle Gear & Machine Co. was rather more so, on account of its higher carbon and special contents. The analysis of this latter was: Carbon, .50; phosphorous, .04; sulphur, .015 to .04; manganese, .60.

In the daily tests, covering a considerable period, nine 3½-in. bars of the latter material were placed on the loading table, and the saw run continuously for 24 hours a day, six days a week. The average cutting time for the entire nine bars, with a 21-in. inserted tooth milling saw blade, was nine minutes, or at the rate of 54 per hour. This is equivalent to seventy-eight 3-in bars per hour, and sixty 3¼-in. bars.

An additional test was made with a saw blade that had been used on almost a thousand bars, and, in spite of the fact that it had not been ground in the meantime, the cutting time for the nine bars was 10½ minutes, the start having been made at 2.29 p.m. and the last steel die falling off at 2.39½. This rate of production, it is understood, is guaranteed by the makers of the "Lea-Simplex" saw to be continuous, and since several of these machines can be handled by a single operator, it follows that both production and labor costs are much reduced.

One of the biggest factors in the quick cutting off of material is a simple and rapid means of handling stock. The accompanying blueprints show very clearly how the stock is fed into the machine, and how the gauge plate in front of it automatically produces the right length.

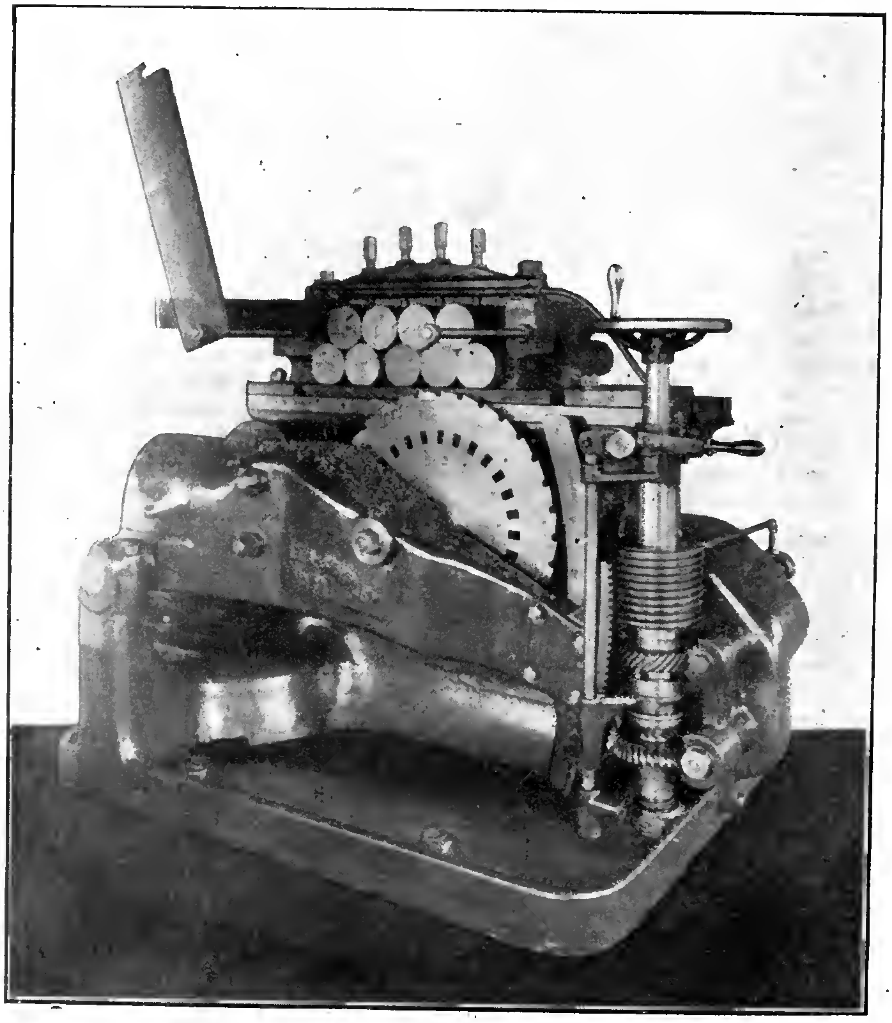
While it is generally possible for the saw to perform the actual cut with great rapidity, whatever advantage may be obtained in this way is frequently offset by inability to keep the machine continuously in motion. Quite naturally sawing must be interrupted during the feeding of new stock, and any decrease that can be made in this time will reflect favorably upon the ultimate production.

In many cases it has been observed that the time for changing stock is almost as great as that consumed in actual cutting. It follows, then, that the actual output of the saw may be restricted. Therefore, any decrease in the time required for placing the work before the saw blade will obviously make an appreciable increase in the output of the machine, even where its actual cutting speed is in no way affected.

With the exception of the new loading table and the new stock feeding device, the machine illustrated is practically the same as the standard No. 21 "Lea Simplex" saw. The frame consists principally of a one-piece casting, with heavy ribs, to insure rigidity. It is provided with three bearings, to carry the main drive shaft and the trunnions of the swing arm. The bearings are provided with self-closing, dust-proof oilers and bushings are of liberal proportions.

The top or work table part of the frame is planed, and has three T-slots machined from the solid and numerous pin holes for fastening and setting clamping blocks when the new form of multiple cutting off table is not used. The base of the frame casting serves as a tank for the cutting compound which is kept in circulation, and used over and over again by a centrifugal pump placed near the gear box.

On work of the nature described in this article it is customary to keep the tank filled with approximately fifteen gallons of cutting compound, and because of the evaporation an additional quantity of about two gallons per day. The compound used in the case of diffi-



EARLE GEAR & MACHINE CO. MULTIPLE BAR SAW.

cult metal consists of one pound of borax dissolved in cold water, to which is added one gallon of lard oil. When this has been thoroughly mixed, enough water is added to fill a three-gallon bucket. The pump is a self-primer.

At one side of the frame a pad is provided for motor support, on which a five horse-power motor is placed, the latter having sufficient speed and pulling capacity for any work that saw may be called upon to do.

The swing arm, which carries the saw blade into the work, is a rigid hollow casting, supported at three points. The three point suspension naturally tends to relieve the bearings of all side thrust and maintain the vertical cutting plane of the saw very accurately. In this way the saw blade is relieved of all twisting strain, and is far less subject to breakage than would ordinarily be the case. This construction also permits of the use of thin saw blades, with a consequent reduction in waste stock.

The outer end of the swing arm is a heavy quadrant, engaging a feed worm. The liberal size of the worm and the large cross section of the swing arm are conducive to very accurate and uniform feeding and prevent strain when the saw blade is suddenly relieved of its load, or where the cross section of metal being cut is either reduced or increased.

The support of the saw is an interesting feature. The bearing is bushed and extremely long in order to minimize wear and tear and obtain rigidity. Removable plates are fastened to the side of the arm to guide the blade and prevent loss of alignment; this assures a smooth, square-cut surface. Hardened tool steel is employed in the guides, being ground to a fit, while ample provision is made for adjustment to take up wear.

The sprocket drive is claimed to be absolutely positive and obviates every danger of slipping. The sprocket itself is secured to a crucible steel spindle, running in bronze bearings. At one end a bevel gear engages a mate on the main drive shaft.

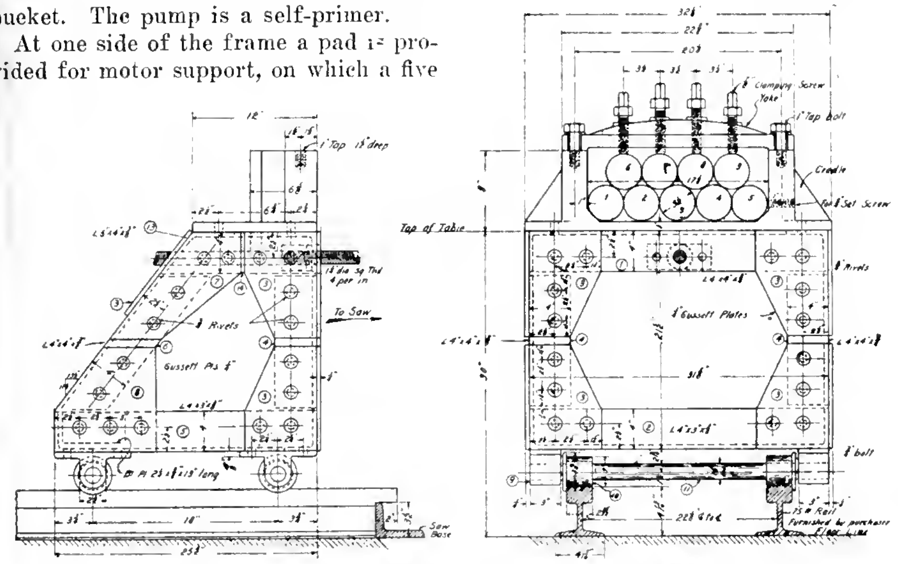
The radial slots in the saw blade, as will be seen in the photograph, are placed as close to the periphery as possible in order to produce a steady, powerful pull on the feed while the swing arm gradually sweeps upward. These changes are made available through a change gear feed box, which is controlled by a calibrated plunger. Its construction permits changes in feed while the saw is cutting.

Probably one of the most interesting and economical little devices used with the machine is the automatic friction control of the feed, which makes it virtually impossible to break the saw blades through overfeeding. A set of friction washers is placed directly on the worm shaft which feeds the swing arm. The resistance of these washers can be adjusted to almost any amount, so that when their predetermined resistance on the saw teeth is reached, feeding stops automatically until the resistance is relieved. The value of this feature is especially emphasized in cases where the annealing or rolling of metal has not been uniform, and hard spots are scattered about its cross section.

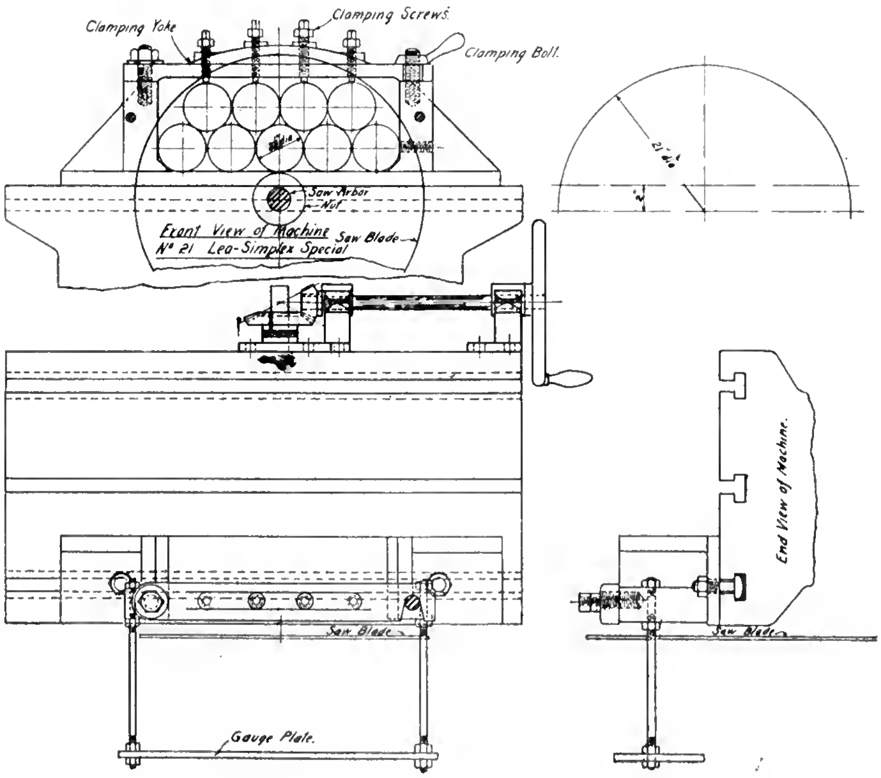
The feed mechanism, which is actuated by the gear box, consists essentially of a vertical shaft carrying a worm and two spiral gears, with a flexible feed return and a control rod for operating the clutch. It can be seen from the illustration how the large worm on the vertical feed shaft engages the quadrant fastened to the swing arm and feeds it up or down as the case may be.

An interesting feature of the control rod—easily seen in the illustration—is the fact that it may be operated by hand or automatically through the agency of adjustable dogs and tripping devices. In this manner the machine can be stopped at any predetermined point automatically. This is a good point, especially in the cutting of shrapnel blanks in multiples, because with the cessation of feeding all the power utilized for raising the swing arm is conserved. The floor space of the machine is comparatively small, although the length of bars employed for cutting shrapnel will largely determine this.

The newly developed rapid feeding



SUPPORTING CARRIAGE FOR CUTTING BARS.



CRADLE FOR CUTTING OFF BAR STOCK FOR SHELLS.

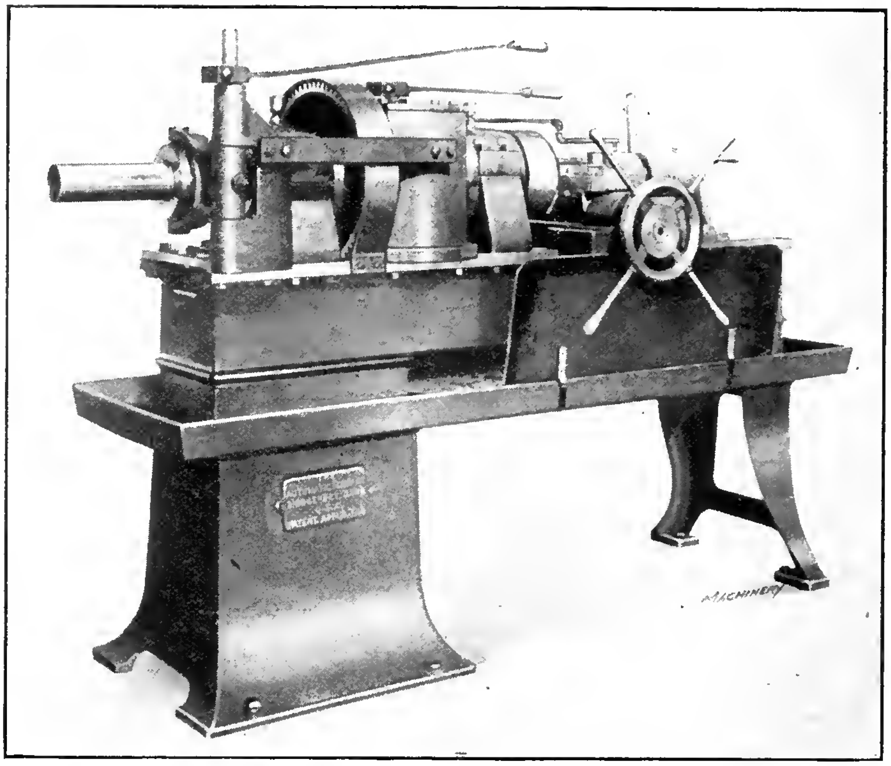
table consists of two units, one of which is mounted on the regular table of the machine, and the other, which consists of a structural steel table, mounted on rollers and running on standard steel rails. The rails are declined toward the front of the machine in order to secure the assistance of gravity in the movement of the stock. The amount of forward movement is controlled by a screw operated by means of a hand wheel placed conveniently on the operating side, which moves the stock positively to any desired distance.

That part of the feeding table which is bolted to the regular table consists of two cast steel cradles and two swinging cast steel yokes fitted with the necessary set screws required to hold the work. The lower part of the table is trussed and otherwise reinforced to prevent any sign of spring or movement whatever.

It is essential when cutting off is done rapidly to provide a means for gauging the length of the finished product quickly and accurately. Two machine studs protruding from the sides of the yoke supports are provided for this purpose, and are adjustable. At the under one a gauge plate, which can be seen very clearly, is swung in a manner that permits its pulling on the other adjusting bolts. When the stock is moved against this gauge plate by means of the bevel gear feed on the stock it is moved far enough ahead to cut possibly within one-sixteenth of an inch of the finished length.

CUTTING OFF MACHINE FOR STEEL AND COPPER TUBES.

THE requirements of the shell industry have justified the production of special machines for producing one- or more similar parts, such as copper bands, etc. The machine illustrated has been designed in response to the demand of shellmakers, but is also suitable for tubular cutting off in various branches of manufacturing such as roller bearings, etc.



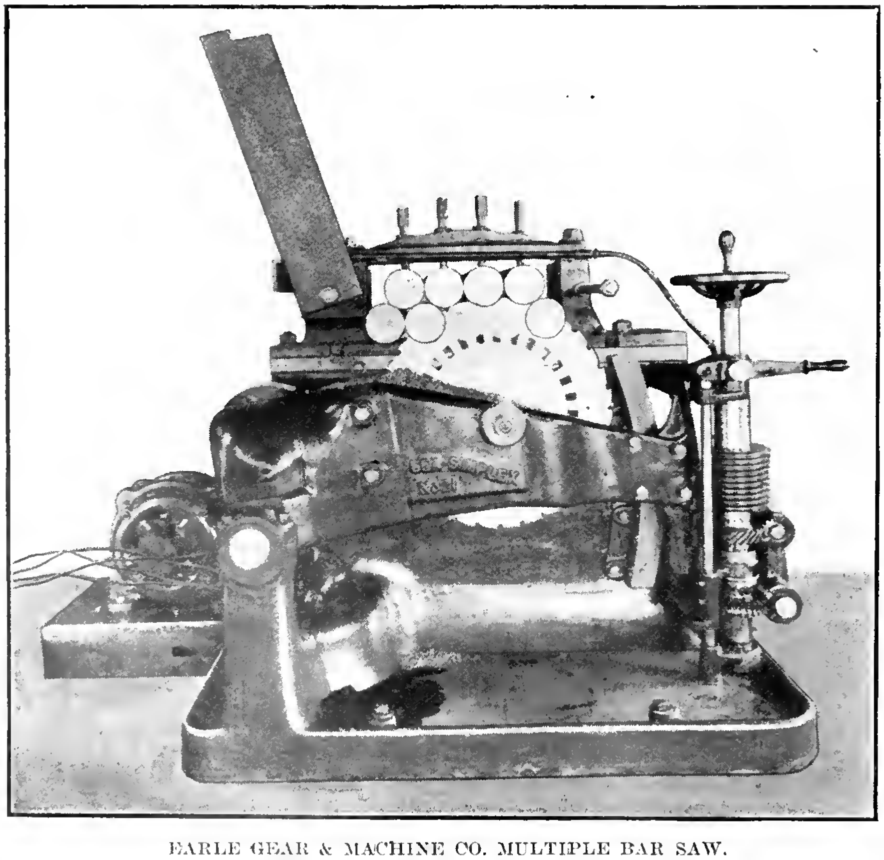
CUTTING-OFF MACHINE FOR STEEL AND COPPER TUBES.

The essential features are a large cast-iron hollow spindle running in cast-iron bearings bolted rigidly to a substantial bed mounted in oil pan with box leg oil reservoir, oil pump and piping. The spindle has spring collet chuck with spring feeding fingers reaching close up back of tube holding chuck.

The operation of the machine is by the two hand levers shown over the headstock and the pilot wheel on cross feed slide. The tailstock or stop has a releasing device so that the revolving tube will not come in contact with the stop while being cut off. The long lever over headstock is for feeding the tube, and the short one is for opening and closing the chuck. The cross feed is by hand, and the tool slide is fitted with multiple tool holder, so that three to six rings are cut off at one time.

The actual time necessary for one cycle of operation, i.e., to feed, chuck, and cut off three to six bands, is less than one minute. The whole machine is well made, rugged, and operates with a minimum of effort by the workman. With modifications, it can be used for trimming either end of shrapnel or high explosive shells, for finish turning the bands, for cutting steel tubing, and many other classes of work where a large hollow spindle with spring collet chuck can be used to advantage.

The machine is made in two sizzes, the smaller one having a capacity through the spindle of 3¾ inches dia., and the



EARLE GEAR & MACHINE CO. MULTIPLE BAR SAW.

larger machine 6¾ inches dia., while both machines have a maximum capacity of 18 inches between face of chuck and stop. They are completely designed with stop, stock support and multiple cutting off tool post, and the equipment includes countershaft, oil pump, pan, tank, piping, guards, and tools for any one size, length and diameter of tube. The net weights are 2,700 lbs., and 3,300 lbs., respectively, while shipping weights are 3,300 lbs., and 4,000 lbs. The Automatic Machine Co., of Bridgeport, Conn. are the builders.

CUTTING-OFF MACHINE FOR SHELL AND SHAFTING WORK.

THE illustration shows a specially designed cutting-off machine for cutting off all sizes of round bars from 1½-in. to 6-in. in vanadium and special alloys steels, as well as shafting bars, etc. It is built for heavy rolling mill work and will weigh approximately 11,000 lbs. The machine as shown is driven by a 20 h.p. motor and is capable of cutting off shell and shrapnel bars at the rate of one cut in forty to fifty seconds on 3-in. round material; other sizes in proportion. It is equipped with two universal chucks and has a double cutting head—one on each end. There are four tools in each cutting head, and four tools working on the material at one time makes it a very rapid cutting-off unit. With this arrangement the tools can be crowded practically to the limit all the time.

It has a special apparatus for backing the tools out by power at the completion of cut, the four tools being handled quickly. It also has an automatic stop which throws the tools out at the end of cut. A receptacle is provided for a liquid for lubricating the cutting knives, and a rotary pump is also provided for pumping the liquid for lubricating the cutters.

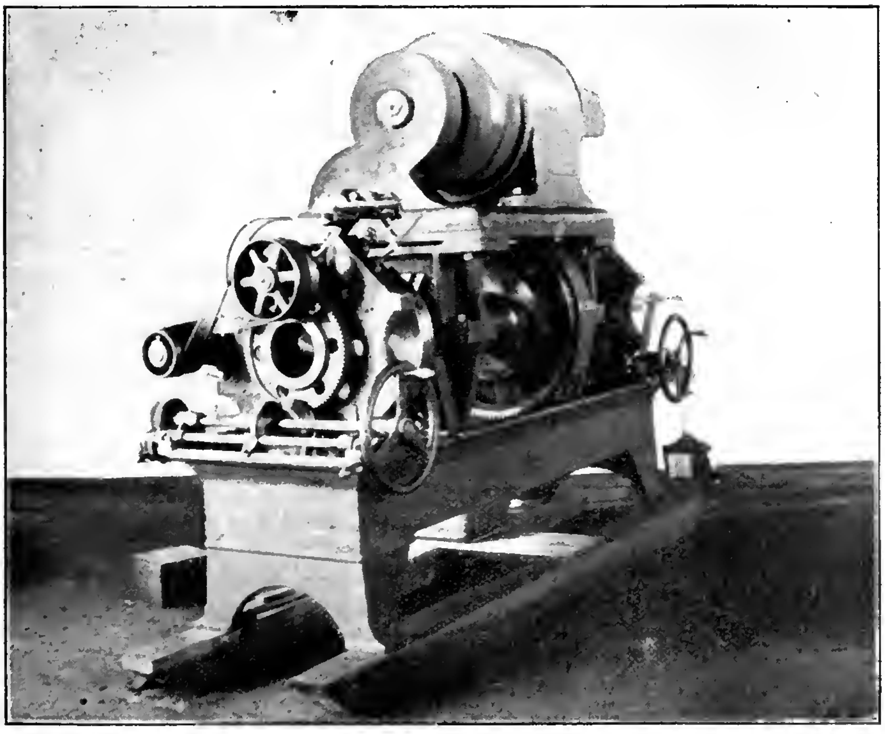
A particular advantage claimed for this machine where it is necessary to cut from ¼-in. to ½-in. stock off the end of long bars is that the bars are put in and one end is cut off by one cutting head; the bar is then pulled through and the other end is cut off by the other cutting head. This eliminates taking the bar out of the machine and turning it end for end.

A further advantage claimed is that in cutting up short lengths into still shorter pieces, such as gear blanks, etc., two pieces can be cut at one time with the double cutting heads. It is also provided with a measuring gauge for short lengths, which is attached to one end to be used in shell and shrapnel work, as well as on short pieces of every description.

When long bars are being cut, two specially designed stands are used, which, it is pointed out, permit the stock to revolve on the stands while being cut off. A cam-operated roll is provided for the stands to place the bar in position to be pushed through the machine without any drag.

The Brightman Mfg. Co., Columbus, Ohio, are manufacturers of this product.

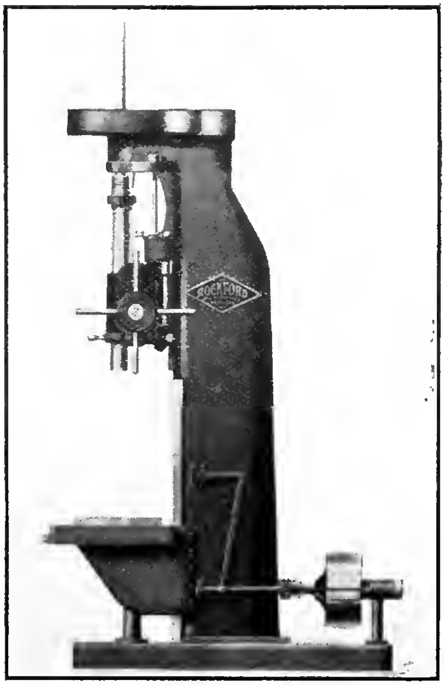
Sackville, N.S.—The Fawcett Foundry Co. are installing machinery for making shells.



CUTTING-OFF MACHINE FOR SHELL AND SHAFTING WORK.

HEAVY DUTY BOX COLUMN TYPE DRILLING MACHINE.

THE description and illustration refer to a heavy duty box column type drilling machine recently developed by the Rockford Drilling Machine Co., Rockford, Ill. It is rigid and heavy, is intended to drive high-speed drills up to 2½-in. in diameter in steel, and weighs approximately 3,000 pounds. It is made in the following arrangements:—



HEAVY DUTY BOX COLUMN TYPE DRILLING MACHINE.

1—With a pulley that gives only one speed and with a friction arranged for the starting and stopping of machine.

2—With a two-step back gear cone and a double friction pulley countershaft that will give four speeds forward and four reverse, or eight speeds forward.

3—With either a direct connected variable speed or constant speed motor. In the construction, only one set of bevel gears is used and these run at a high speed. The power at the top is transmitted to the spindle through three spur gears, the reduction being five to one. All gears are of steel with the exception of the large drive gear on the spindle; it is made of semi-steel. The spindle is of special high carbon steel and the rack of nickle chrome steel.

The feed is taken from the spindle and has a feed box that gives four different feeds, these being instantly obtainable by turning a small lever upward and downward. The hand feed is through a star lever which in its inner position, works directly on the cross spindle and gives a quick approach and return of the spindle. In its inner position, it works through reduction gears which give a very powerful feed for

hand facing or drilling. The trip is by means of a dial graduated to correspond with the graduations on the sleeve; a trip lock can be set to automatically trip the feed at any pre-determined depth. The worm wheel is of bronze and the worm is arranged so that it runs in an oil bath. The table has three "T" slots frough 4-in. diameter by 3-in. deep.

EQUIPMENT FOR AUSTRALIAN NAVAL DOCKYARD.

TENDER forms, specifications and drawings have been received by the Department of Trade and Commerce, Ottawa, from D. H. Ross, Canadian Trade Commission at Melbourne, covering machinery equipment required for the Commonwealth Naval Dockyard, Cockatoo Island, Sydney, N.S.W. Details of the requirements, including closing dates of tenders, are as follows:—

Section A.—Three 1,000 k.w.d.c geared turbine generator sets as per plan, viz., boilers, mechanical stokers, economizers, feed pumps, superheaters, piping and valves, coal and ash conveyor, crane, 1,000 k.w.d.c. geared turbo set, 225 k.w.d.c generator, rotary balancers, main switchboard and cables, condensers.

Section B.—Three 500 k.w. triple expansion reciprocating sets; two 750 k.v.a. mixed pressure exhaust turbine alternators—viz., boilers, mechanical stokers, economizers, feed pumps, superheaters, piping and valves, coal and ash conveyors, crane, 500 k.w. reciprocating sets, 750 k.v.a. mixed pressure turbines, 225 k.w. generator, rotary balancers, switchboard and cables, condensers.

Section C.—Three 500 k.w. triple expansion reciprocating sets; two 750 k.w.d.c. mixed pressure exhaust turbine generators—viz., boilers, mechanical stokers, economizers, feed pumps, superheaters, piping and valves, coal and ash conveyors, crane, 500 k.w.d.c. reciprocating sets, 750 k.w. mixed pressure geared turbines, 225 k.w. generator, rotary balancers, switchboard and cables, condensers.

Section D.—Five 600 k.w.d.c. Diesel engine sets, viz., 600 k.w.d.c. Diesel sets, 225 k.w.d.c. Diesel sets, rotary balancers, switchboard and cables.

Machine Tools for Engineering Department of Dockyard.

Machine Shop.—Turbine boring machine, vertical and horizontal planing machine, horizontal boring, tapping, studding, drilling and milling machine, horizontal drilling, tapping and studding machine, high-speed turbine rotor lathe, shafting lathe, heavy double-ended, heavy duty lathes, high-class lathe, high-speed high-class lathe, high-speed vertical boring mill, vertical turning and boring mill, vertical boring and turning mill, face plate lathe, cylindrical grinding machine, broaching machine, horizontal planing machines, slotting machine, vertical shaping machine, shaping machines, gear generating machine, bevel gear cutting machine, thread milling machine, band saw, vertical grinder, double-headed disc grinder, cylindrical grinder, boring and facing machine, vacuum cleaning plant.

Brass Finishers' Shop.—Brass finisher's turret lathe, brass finishers' surfacing and boring lathe, duplex cock turning lathe, screw cutting lathe, grinding machine, high speed shaper, boring and facing machine, horizontal drilling machine, condenser ferrule making machine, double-headed disc grinders, ribbon grinder, automatic screwing machine.

Tool Shop.—Sliding, surfacing and screw cutting lathes, high class horizontal planing machine, universal milling machine, die sinker, high class shaping machine, radial drill, thread milling machine, grinding machine, hydraulic press, hydraulic vertical plate bending machine, hydraulic riveting machine, hydraulic joggling machine, high speed friction saw, hydraulic portable riveting machine, manhole cutting machine, large hydraulic press, set rolls, multiple spindle drilling machine.

Bolt Shop.—Automatic screwing machines drop hammer, nut facing machine, multiple head tapping machine, hot press nut machine.

Turbine Shop.—(Blading Room).—Packing piece cutting-off machine, blade tipping machine, horizontal multiple-blade drilling machine.

Coppersmith Shop.—Pipe screwing machines, pipe bending machine, punching and shearing machine, circular saw, hack saw.

Pattern Shop.—Disc grinder.

Electrical Shop.—3½-inch lathe, 6-inch lathe, pipe-cutting machine, shaping machine, pipe screwing machine, combined wet and dry grinding machine, punching and shearing machine, radial drilling machine, universal milling machine, coil winding machine, armature coil taping machine, vacuum drying and impregnating plant.

Platers' Shop.—Hydraulic joggling machine, hydraulic manhole punching machine, notching machines, double punching machines with side shears, bulb angle and double bar shear and beam bending machine, plate slitting shears, band saw, plate straightening rolls, horizontal drills, punching and shearing machines, double tool grinders, pneumatic hammer, bevelling machine, hydraulic frame benders, punching and shearing machines, radial countersink drilling machines, bulb angle and double bar shears and beam bending machine, plate slitting shears, horizontal drills, band saw, plate bending rolls, manhole punch, plate joggling machine, plate flanging machine.

Fitting Shop.— Planing machines, slotting machine, double-headed shaping machine, universal miller, high speed sensitive pin drills, high speed boring and surfacing machines, high speed radial drilling machines, variable speed combination turret lathe, variable speed hexagon turret lathe, variable speed gap lathe, hollow spindle friction capstan lathe, variable speed hollow spindle flat turret lathe, double grinder, side disc grinder, band saw.

Plumbers' Shop.—Single head pipe screwing machines, pipe flange face grinder.

Joiners' Shop. — Automatic knife grinding machine, pendulum saw, Perkins or other hand trimmer, planing machine.

Shipwrights' Shop.— Electric deck planing machine, planing machine, boring machine, steam hammers, steam hammer, steam olivers, forge steam hammer.

Tenders should be addressed to the Director of Navy Contracts, Navy Office, Melbourne, Australia. The departure of mails, by which tenders can be submitted within the contract time, from San Francisco and Vancouver, are as follows:—From San Francisco, September 28, due at Melbourne October 19; from Vancouver, September 29, due at Melbourne October 23. There is no duty on naval supplies.

Tenders for the various items close at Melbourne on October 25, 1915.

EMERY FACED WHEELS FOR POLISHING SHRAPNEL SHELLS.

IN a recent article in the Brass World, James Haslip makes some pertinent remarks regarding the care and preparation of wheels which are at present being widely used by shrapnel makers to polish the spots where the hardness of the shell has to be tested:—

"The glue room should be separate and especially arranged, drafts from windows and doors being avoided so that the thin layer of glue will not chill on application to the wheels. Glue of any kind should be soaked in cold water several hours before heating. Being of animal matter, it is quickly decomposed by heat if soaked in hot water, and its strength impaired. Glue should never be boiled after being soaked and heated; no further melting is necessary It should be kept constantly at a temperature not exceeding 160 deg. Fahr. The glue pots should be thoroughly cleaned before refitting, no scum being allowed to accumulate. . . . . No glue should be used the second day as the strength will be impaired about 50 per cent. by standing over night, and thickened glue diluted, never has its original strength.

INDUSTRIAL PATRIOTISM!

ALL accounts regarding the production of munitions in Britain, indicate an urgency in the matter which is now far from making itself manifest in Canada. Ten months ago, the few Canadian firms who had been awarded portions of the first shell order were being pressed for delivery in a manner which was probably truly indicative of the urgency which then existed.

Happenings in Europe since that time do not indicate any decrease in the urgency, but the present condition of the shell industry in Canada does not coincide with the state of affairs which obtains in England and Scotland at the moment.

Advices from England betray a feverish activity as a result of the campaign waged so effectively by the Munitions of War Minister. Four months ago Canada's efforts were approaching a degree of intensity which has only been reached in England during the last few weeks, and these efforts would have been more productive and vigorous now, had not the "fixing" bogey appeared on the horizon. While the question of fixing the ammunition is being overcome in a manner which may ultimately be satisfactory, the sudden and altogether unexpected appearance of this demand and the circumstances under which it was allowed to develop, did much to detract from the enthusiasm which was being displayed in Canadian engineering circles.

Industrial Patriotism was indeed at high tide, numbers of unemployed workers were being rushed for the first time in years, and hungry men were once more able to buy a square meal and those who could raise capital for shell making were more than willing to do so. Stagnation in various dispensable branches of business had thrown men out of work who on account of years or other physical disability, were unfitted for active service. These and many others who were unaccustomed to manual labor were therefore available for service in shell factories, and proved by their efforts that they were both actuated by a genuine desire to help their country in its hour of need, and incidentally glad to again become wage-earners.

Matters in England and Scotland have not only developed to the stage which has already been attained in Canada, but have gone to a point which we hope will never exist in this country. We refer to the labor situation. The attitude of certain workers in Britain during recent weeks will remain a most unpleasant memory in years to come.

The extent to which in time of war a man is willing to surrender his personal liberty and freedom, and devote his entire energies towards assisting his native land, is perhaps the best possible standard by which to gauge the depth of his patriotism. Measured in this light, the activity of Munitions Tribunals in all parts of Britain indicate a lack of patriotism which will give the Kaiser's satellites a further opportunity for sarcastic comment. One feature of Canada's participation in the war has been the absence of internal strife and dissension between employers and employed. Employees are entitled to all the benefits and advantages which they can obtain as a result of active organization, and they are just as much aware as any other members of civilized society that their activity in peace time is fruitful just as it may be in accord with law and the rights of others.

Every day it becomes more evident that the engineering industry is truly the Empire's Reserve. Credit, money, finance, legislation, all are of no value to a nation which cannot give concrete expression to these abstract influences. Industrial patriotism as exemplified by Canada represents the real conception of a nation's duty, and in days to come not the least of the credit will belong to those who, whether masters or men, laid self aside and despite disappointments, delays and discussions, maintained a singleness of purpose which has contributed to place Canada high in world esteem.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, August 23, 1915.—The general market conditions in the industrial field show little change. The demand for war munitions continues to keep a large number of manufacturing plants running at full capacity. The increasing cry for war material, especially shrapnel and high explosive shells is the means of keeping the market on edge, as many who wish to help in the production of these commodities are largely handicapped by their inability to get the required equipment.

Steel.

The steel market opened the week active and strong, with a heavy demand for steel bars and billets as the feature. Inquiries for large tonnage, particularly in the States, have recently been reported, one European nation inquiring for 200,000 tons of bar and billet stock. The price of round stock used in the production of high explosive shells has been advancing steadily and is now quoted at about $1.50 per 100 pounds above that of a few months ago. Although the tension is at present a little relieved, there are indications that further advances may shortly be realized, as many mills are working to capacity on orders booked for several months ahead.

Pig Iron.

Quotations for pig iron show no appreciable change. The demand for certain grades is somewhat improved over that of a week ago and the tendency is toward a gradual improvement generally.

Scrap Metals.

Prices on old material generally remain firm. Old copper is slightly lower than a week ago, as is also heavy lead.

Machine Tools and Supplies.

The demand for machine tools is not so evident as a few months back, although numerous inquiries are abroad for different classes of lathes. It is still practically impossible to get deliveries on certain tools, especially those required in the manufacture of shells, under eight or ten months. The situation continues to be somewhat relieved, however, by the supply of special attachments to machines already installed.

Toronto, Ont., August 26.—Business conditions generally continue to improve, large orders for war material are swelling the volume of exports and also helping to stimulate domestic trade. The remarkable increase in the export trade of Canada for the first four months of the fiscal year is shown in the returns recently published by the Department of Trade and Commerce. The exports this year increased $38,430,813 over those of the corresponding period last year, while the imports decreased $36,000,535. The significance of the figures contained in this report is in the fact that the balance of trade is becoming increasingly favorable.

The announcement, made recently, that the Dominion Government propose to offer a bounty on the production of refined zinc will stimulate this industry and help materially to ensure a supply of this metal at a reasonable price. The proposed bounty will be on a sliding scale and will not exceed two cents per pound when the standard price of zinc in London falls below $33 per short ton. This arrangement has been made primarily to ensure a sufficient supply of brass for munitions.

CANADIAN GOVERNMENT PURCHASING COMMISSION.

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George Gault, Winnipeg; Henry Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Steel Market.

The steel trade continues very active on orders for war materials. The mills producing bars and forgings for shells are working to capacity and are just about keeping pace with the demand. The Steel Company of Canada, Hamilton Works, is increasing its open hearth capacity and also installing more presses for shell forgings. Prices are unchanged but very firm. The trade is enjoying a period of prosperity which seems likely to last for some time, especially with regard to exports which are developing in a satisfactory manner.

The high speed tool steel situation is causing considerable anxiety on account of the shortage of supplies and increasing demand. A company has established a plant for making tungsten powder in England but the output at present is too small to be of any appreciable help. It is reported that tungsten mines in Burma will be worked more extensively but it will take some time to overtake the demand. Prices of high-speed steel are away up and will likely advance further, although the difficulty of obtaining steel is the most serious feature.

The galvanized sheet market is weak on account of the further decline in spelter. Prices of sheets have not changed but may be reduced any time, although not to any marked extent as prices of raw materials have an upward tendency. Galvanized pipe is unchanged although quotations have a weaker tendency due to the decline in spelter.

Conditions in the steel trade in the States continue to improve and foreign buying is still increasing. Russia has placed large orders for rails with American mills and it is understood that others are pending. There is still a very heavy demand for steel rounds for shells but the mills are now so well filled up that they are not in a position to take much more work for delivery this year. The United States Steel Corporation is operating at about 90 per cent. capacity. Prices on bars and billets are very firm and have an upward tendency.

Pig Iron.

Quotations on American brands are firmer and at higher prices in some cases. Grey forge iron has again advanced and is now quoted at $14.20 Pittsburg. Quotations on Lake Superior charcoal are higher, being quoted at $16.25 Chicago. Domestic brands are unchanged.

Scrap Metals.

The market is easier for most scrap metals except heavy melting steel which has advanced to $8 on good demand. Scrap copper and lead are weaker but unchanged.

Machine Tools.

There is practically no change in the general situation. There is quite a brisk demand for new machine tools but deliveries are so backward that dealers hardly know what to do. This condition has greatly stimulated the demand for second-hand equipment and dealers in this class of machinery are doing a fine business. Makers of tools and special fixtures are also exceptionally busy.

Supplies.

Business continues very brisk in machine shop supplies for the regular lines, the demand being almost entirely from shops making shells. There are no price changes to note this week except solder, "half-and-half" which is lower on account of weakness in the tin market. "Half-and-half" is now quoted at 24¾c per pound. The turpentine market is weak and lower prices may be expected. Linseed oil is unchanged but the market continues very unsettled. An advance in waste may be announced any time but no change has been made as yet.

Combined Shrapnel and High Explosive Shell Manufacturing Plant

Staff Article

An installation such as here described puts the onus of successful production largely on the machine tool builder, and, as to how the latter has met the requirement as far as 3.3 shrapnel and high explosive shells are concerned, a careful study of the illustrations and text data will make the position clear. It will also evidence the ingenuity of the management.

THE plant here described is one of the most modern and up-to-the-minute mechanical engineering establishments in Canada. It is working night and day, producing both shrapnel and high explosive shells. Everything has been carefully planned, no detail having been overlooked in the placing of the multitude of machines required for the systematic handling of large numbers of shells. As these progress through the shop, the machines are so arranged that a minimum amount of effort is required in the removal of one series of shells from one operation to another.

Routine of Work.

The rough bars or billets enter the shop at one end and continue from one group of machines to another until they reach the other end; they are then transferred to the floor above and continue in the opposite direction until they again reach the entrance end. By this time they have been finally inspected and are ready for shipment.

Stock Yard.

The first view one gets upon entering the yard leading to the shell department, impresses the observer with the extent of the operations that must successively follow. Fig. 1 shows a view of the stock as it is received from the mill. The pile of billets to the left of the track is for the making of 3.3 shrapnel shell, and the piles of steel bars to the right are to be cut into lengths for the production of 3.3 high explosive lyddite shells; in the background is a view of the shell department building.

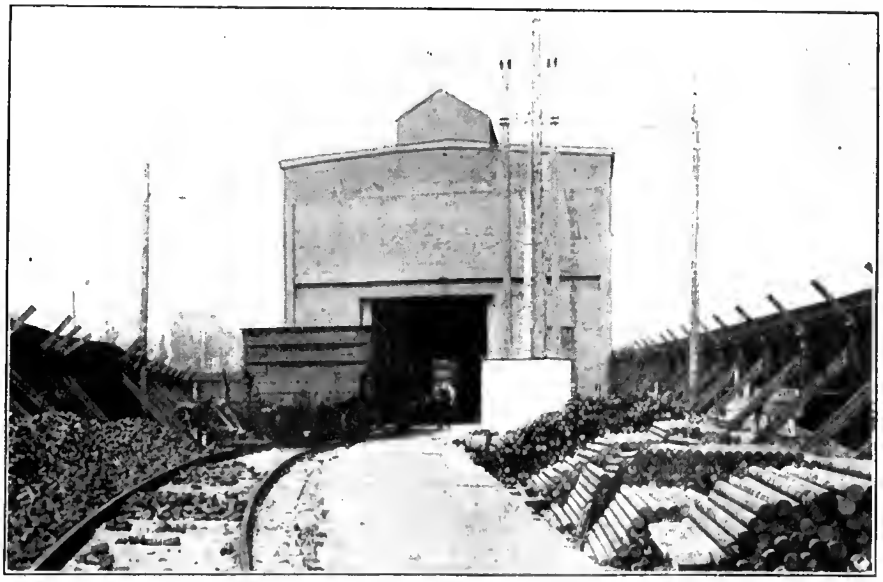

FIG. 1. VIEW OF YARD SHOWING STOCK OF SHELL BARS AND BILLETS. SHELL SHOP IN BACKGROUND

Shell Shop Features.

The shell shop was especially erected for the manufacture on a large scale of both 3.3 shrapnel and high explosive shells. The building is a two-storey steel structure 400 feet long and 50 feet wide. The ground floor is of concrete and the upper floor double boarded.

Lighting.

Light is received from a row of large windows running along both sides while, in addition the top floor is lighted by a skylight the full length of the building. Directly above the large hydraulic presses is an opening which allows a considerable amount of light to penetrate to the lower floor. Artificial light is obtained from thirty-two globes at equal intervals along both sides of the shop, each globe containing a cluster of five tungsten lamps. Each individual machine is equipped with a Wallworks, Manchester England light stand, the wires from which are placed in pipes,

and run beneath the cement floor to the walls on either side.

Heating and Fire Protection.

The building is heated by steam; pipes running along the walls on both sides the full length of the shop. It is also fully equipped against fire, being furnished throughout with a sprinkler system and "Dominion" fire extinguishers, which are placed at intervals along each wall.

Grouping of Machines.

The machines are placed in a number of groups on either side of a centre aisle, each group being driven by a 30 or 35 horse-power "Vickers" motor, the belting for same being supplied by the Beardmore Belting Co., Toronto. The machines are so arranged that the shrapnel shells progress along one side, while the high explosive shells advance along the other side.

FIG. 2. "MECHANICAL ENGINEERING CO." FURNACES FOR HEATING AND REHEATING BILLETS.

Shrapnel Shell Forging.

The shrapnel shell billets after entering the shop are taken to the three Mechanical Engineering Co. oil furnaces shown in Fig. 2, where they are heated and prepared for piercing. When ready, they are placed in one of the 250-ton Boomer & Boschert hydraulic presses shown in Fig. 3, leaving same in a shape similar to Fig. 4, and constituting the first piercing operation. The pierced billets are again heated and placed in a 200-ton B. & B. press, from which they emerge as finished forgings. A view of the drawing die is shown in Fig. 5 and the punch in Fig. 6.

The sketch Fig. 6A shows the device employed for cooling the punch. This is moved up and down around the punch while a strong stream of water is forced out of the small holes in the ring.

Cutting to Length.

After the shells are forged, they are tested for the thickness of the wall. Following this inspection, they are taken to two "Hall" cutting-off machines where the rough open end is trimmed off.

Rough Turning.

They are then centered on a jig in several Foote-Burt drilling machines after which they pass to ten C.M.C. 16 inch lathes and are rough turned over the complete surface, the mandril for driving being similar to that shown in Fig. 7. Here this plant differs somewhat from others in that the shell is rough turned to the one size its full length. The rough shell is, however, somewhat longer than otherwise, due to the required subsequent nosing operations.

Boring.

The shells are again tested for wall thickness and then taken to twelve 25-inch C.M.C. turret lathes where the powder recess is finished. The base is next finished on four "Hall" cutting-off machines.

Bottling.

The shells are now gathered into groups of 120 each, and are taken to the bottling presses in readiness for forming the nose. It might be stated that the hardening of the shells customary in most plants is dispensed with here as the nature of the steel as it comes to the shop and after drawing leaves the shell of the proper hardness. This is the only plant in Canada using 75 per cent. carbon steel. The latter is somewhat harder to work, but by using "Double Mushet" tool steel this disadvantage has been much minimized, an average of 45 shells being rough turned in ten hours with very little touching-up of the cutting tools.

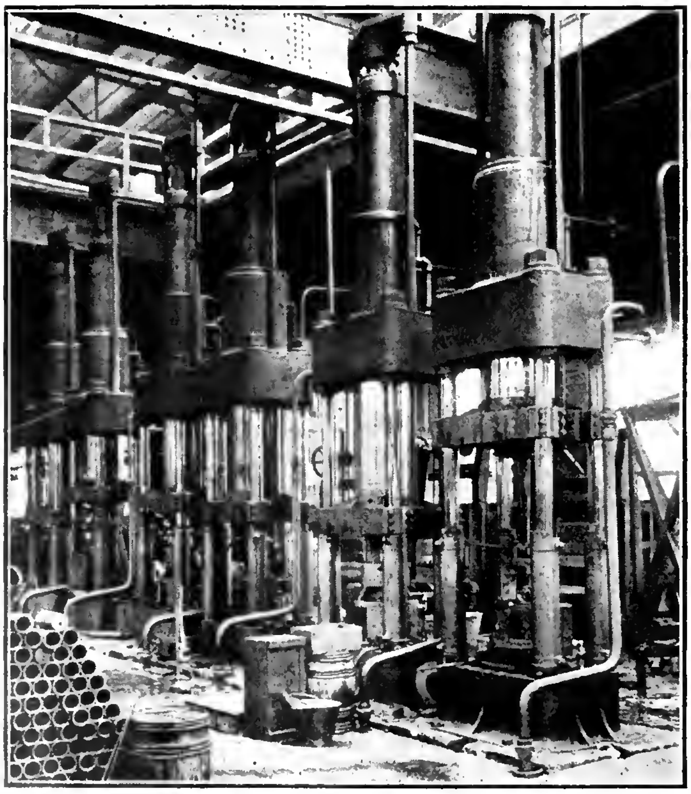

FIG. 3. THREE EACH, 250-TON "BOOMER & BOSCHERT" PIERCING AND DRAWING PRESSES.

The nosing or bottling is done in two operations, and the dies are so constructed that after the second operation the shape is almost the desired form, and requires very little machining. The dies for the two operations are shown in Figs. 8 and 9. When heating for the first operation, the open end of the shells in sets of four are placed in a vertical position in openings at the top of a "Mechanical Engineering Co." oil furnace, arrangements being made to revolve the shell while being heated. The first operation requires heating of about 2 inches or more back from the open end, and after the first process the nose is again heated in another M.E. furnace for a distance back of about ¾ of an inch, the nose being finished in the die shown in Fig. 9.

Water-Cooled Oil Furnaces.

All these oil furnaces are water-cooled, each having a water chamber between the fire-brick and the outside casing. After the bottling operation is completed, the noses of the shells are annealed for further machining.

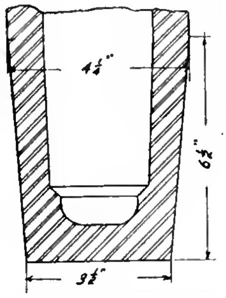

FIG. 4. SHRAPNEL BILLET AFTER FIRST DRAWING OPERATION.

Finishing and Threading Nose.

The shells are next taken to eight-16 inch. "C.M.C." lathes, fitted with turret heads and carrying a special chuck similar to Fig. 10. Thirty or forty of these chucks are in continual use. After the machining is done on the nose of the shell they go to two "Lees-Bradner" machines, where the thread in the nose is milled out. A view of these machines is shown in Fig. 11.

Finish Turning.

When threaded they are then finish-turned and the contour of nose formed by means of a fixed templet at the back of the lathe which takes care of the lateral movement of the tool-post rest.

Waving and Grooving.

The shells are now taken to five 16-inch "C.M.C." lathes, where they are held in a chuck similar to Fig. 10, and have the groove roughed out. They are afterwards taken to five 16-inch "C.M.C." lathes to have the waving and undercutting performed by means of a "Bertram" waving attachment. On account of the nature of the steel the roughing and finishing are done on separate lathes to save the cutting tools.

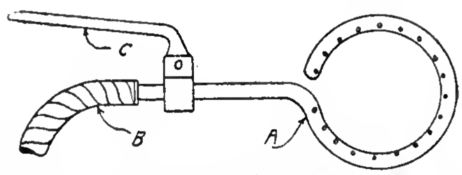

FIG. 6A. DEVICE FOR COOLING PUNCH OF FORGING PRESSES.

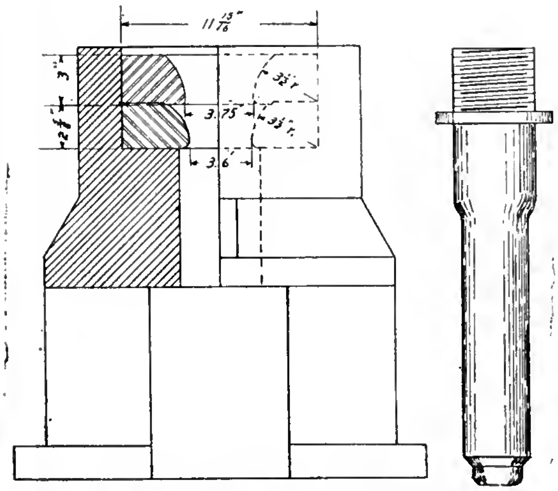
Final Operations.

The foregoing completes the operations as performed on the ground floor. The shells are therefore transferred by means of "Chapman" and "Cowan" elevating trucks to an "Otis-Fensom" hoist and raised to the upper floor where they are filled with shot and resin and have the final operations completed. They are finally lowered on another hoist, ready for shipment.



FIGS. 5 AND 6. DRAWING DIE AND PUNCH FOR FINISHED SHRAPNEL FORGING.

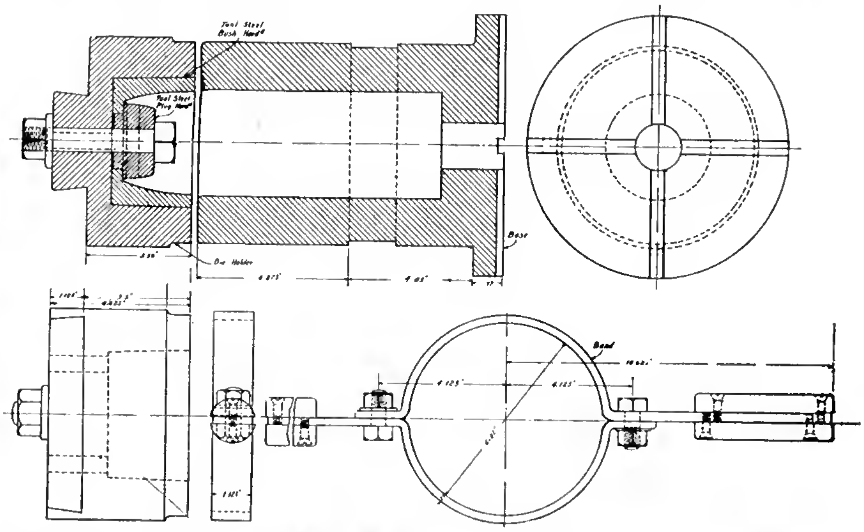


FIG. 8. DIES FOR FORMING SHRAPNEL SHELL NOSE—FIRST OPERATION.

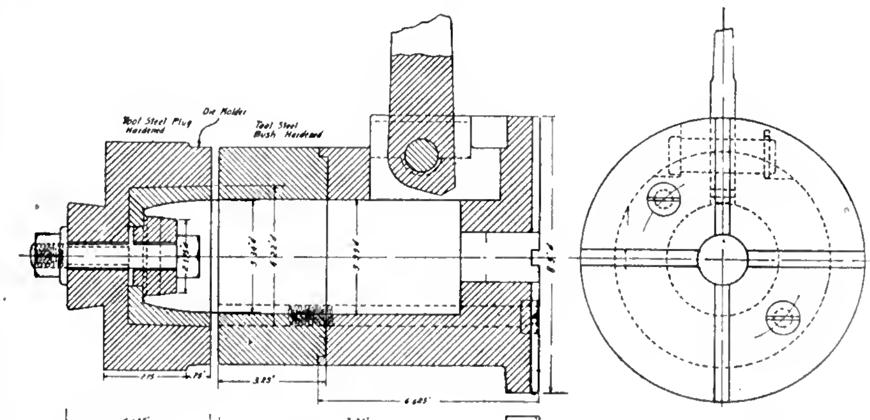

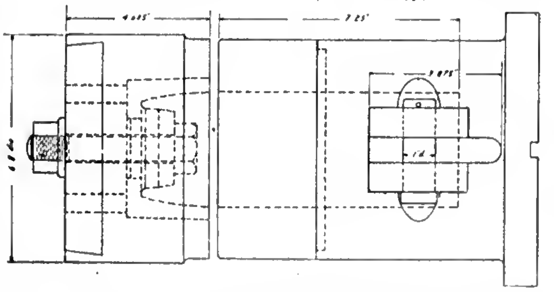

FIG. 9. DIES FOR FORMING SHRAPNEL SHELL NOSE—SECOND OPERATION.

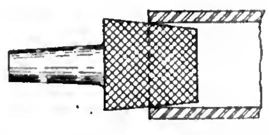

FIG. 7. DRIVING MANDRIL FOR ROUGH TURNING SHRAPNEL FORGINGS.

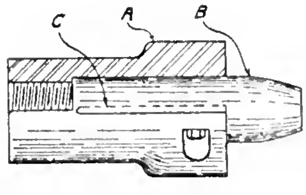

FIG. 10. SPECIAL GENERAL PURPOSE CHUCK.

A general view of shell shop with its multitude of tools is shown in Fig. 20, which is the illustration used in the title of our article.

High Explosive Shell Production.

The material for the production of 3.3 high explosive shells comes to the plant from the mill in bars as shown to the right of Fig. 1. These bars are brought into the shell shop and are first

cut into billets on an "Espen-Lucas" inserted tooth cold saw, driven by a 15 h.p. "Vickers" motor.

Rough Drilling.

The billets are placed in a jig and drilled in a battery of six "Foote-Burt" drilling machines, the drills used being furnished by the Celfor Tool Co., and the Jno. Morrow Co. After they are

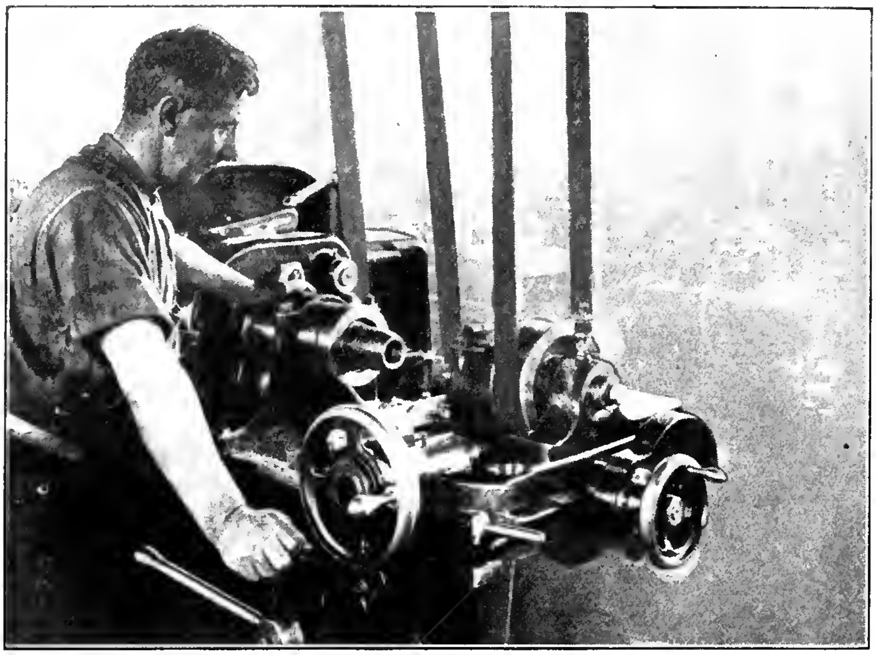

FIG. 11. THREADING NOSE OF HIGH EXPLOSIVE AND SHRAPNEL SHELLS ON A "LEES-BRADNER" THREADING MACHINE.

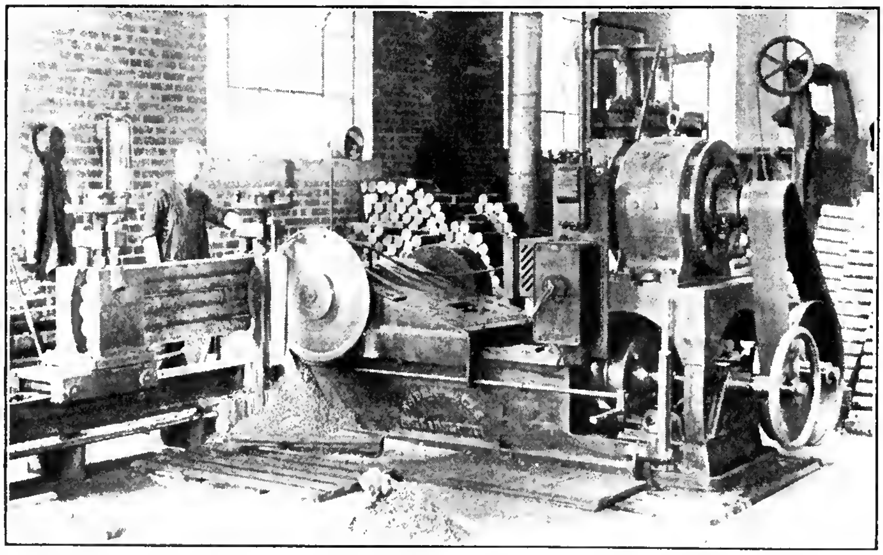

FIG. 12. "ESPEN-LUCAS" COLD SAW CUTTING-OFF BILLETS FOR 3.3 H. E. SHELLS.

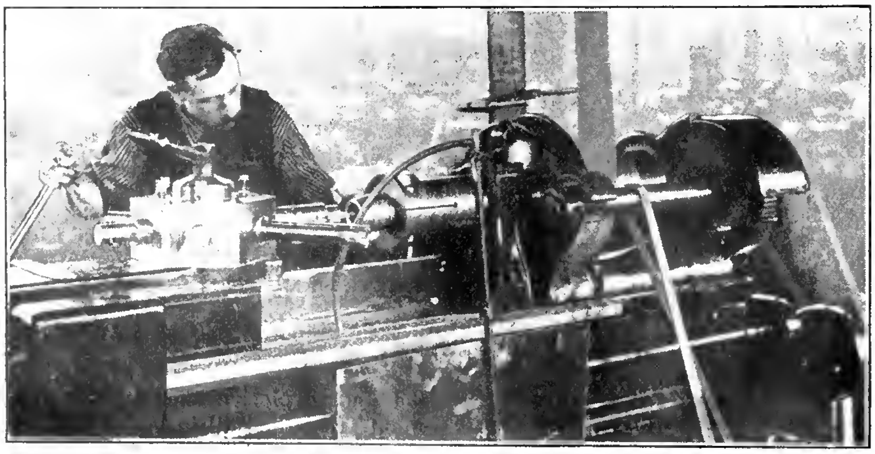

FIG. 15. TURRET OPERATIONS ON NOSE OF 3.3 HIGH EXPLOSIVE SHELLS.

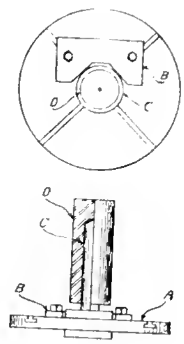

FIG. 13. CENTERING JIG.

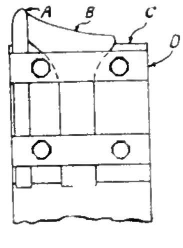

FIG. 14. NOSE FORMING TOOL.

rough drilled they are placed on a jig similar to Fig. 13 and centered.

Rough Turning and Boring.

The billets are then taken to eight 16-inch "C.M.C." lathes to be rough turned and have the contour of the shell nose formed by tools shown in Fig. 14; the tool A is for roughing, and tool B

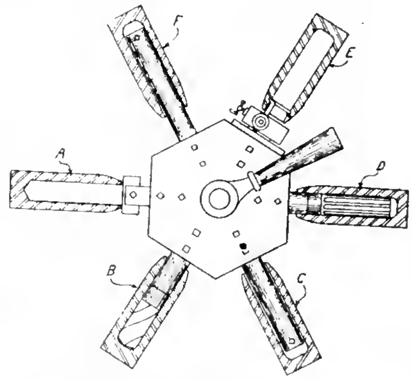

FIG. 15A. TURRET LAYOUT FOR FACING NOSE AND FINISHING INSIDE OF SHELL.

for finishing, the profile of nose. The shells are next taken to six "C.M.C." lathes fitted with turrets, and on these the boring and finishing of the inside of the nose is performed as shown in Fig. 15. The cycle of operations is shown in Fig. 15 A, and consists of facing, drilling, roughing powder chamber, reaming, recessing at bottom of thread, and finishing powder chamber.

Threading and Finish Turning.

The threading of the nose is done on

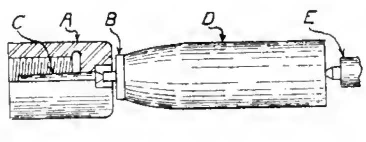

FIG 16. DRIVING CHUCK FOR FINISH TURNING.

two "Lees-Bradner threading machines as shown in Fig. 11. The shells are then finish-turned on six "C.M.C." lathes, the driving being done by means of the chuck shown in Fig. 16. Grooving and waving are performed on six

"CMC" lathes fitted with a "Bertram" waving attachment.

Finishing Nose and Base.

Finishing the nose to receive the brass sockets is done on four R. McDougal Co.

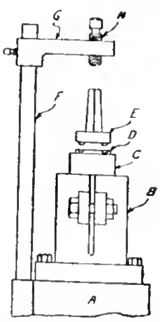

FIG. 18. JIG FOR SCREWING IN STEEL BASE PLATES.

18-in. lathes. The turret operation on the base of the shell to receive the steel disc is indicated in Fig. 17.

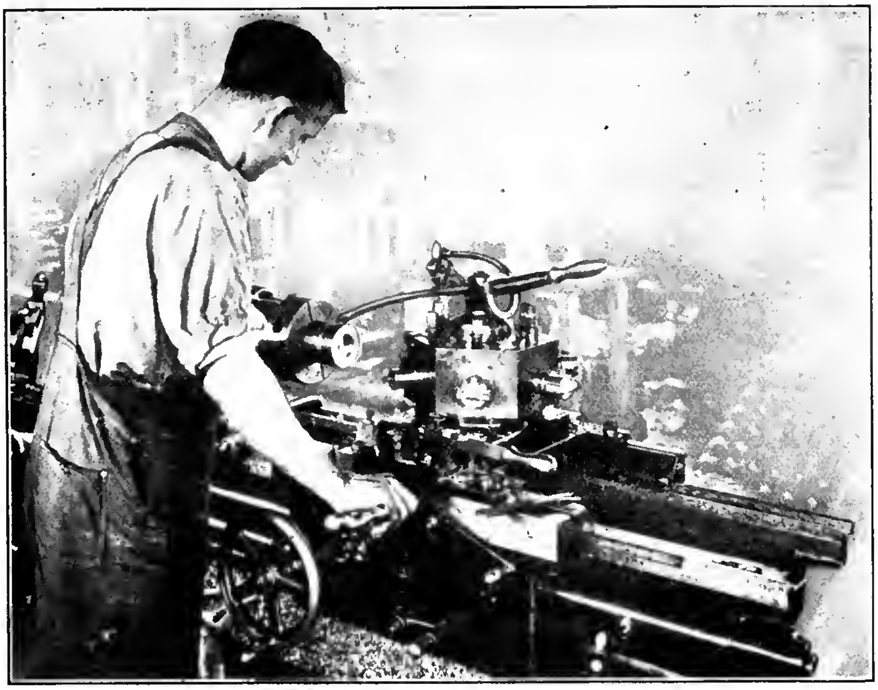

FIG. 17. FINISHING BASE OF HIGH EXPLOSIVE SHELLS ON "McDOUGALL" LATHE FITTED WITH TURRET HEAD.

Drilling and Tapping Nose.

The shells are now carried on "Chapman" and "Cowan" elevating trucks to the hoist where they are removed to the second storey. The grub screw holes are drilled and tapped in the nose and a finishing tap is run into the latter to bring the thread to the required size. The copper bands are next pressed on with a pressure of 700 to 800 lbs. per sq. in.

Screwing in Base Plates.

The steel base plates are screwed tightly in by means of the jig shown in Fig. 18. Two ½ inch holes are drilled diametrically opposite, flat bottomed and about 3-32 in. deep, so that they will be completely removed when plug is turned off flush. The stand A is firmly secured to the floor and the chuck B is bolted to the base. The shell C is rigidly clamped in piece B and the plug entered in its place; the support G for the ratchet is fastened to the piece E; the piece E having a shank which fits the socket of the ratchet and also fits the holes in the disc.

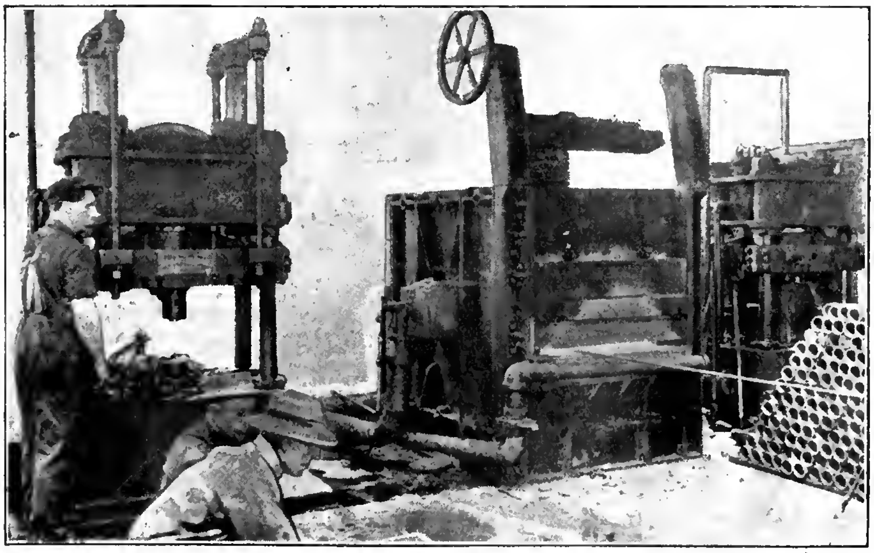

FIG. 21. "MECHANICAL ENGINEERING CO." OIL FURNACE AND "BOOMER & BOSCHERT" PRESSES FOR PRODUCING SHRAPNEL SHELL DIAPHRAGMS.

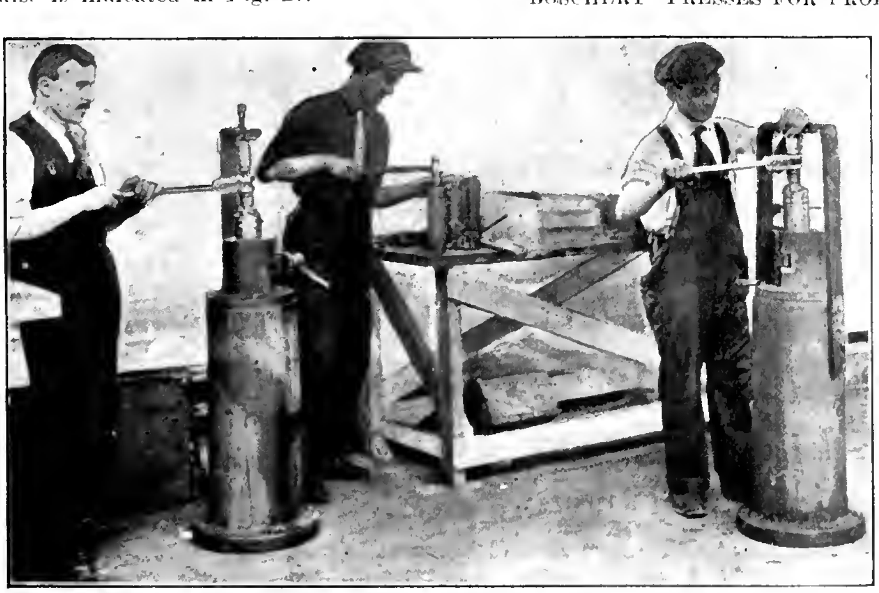

FIG. 19. SCREWING AND RIVETING REINFORCING DISCS INTO BASES OF HIGH EXPLOSIVE SHELLS.

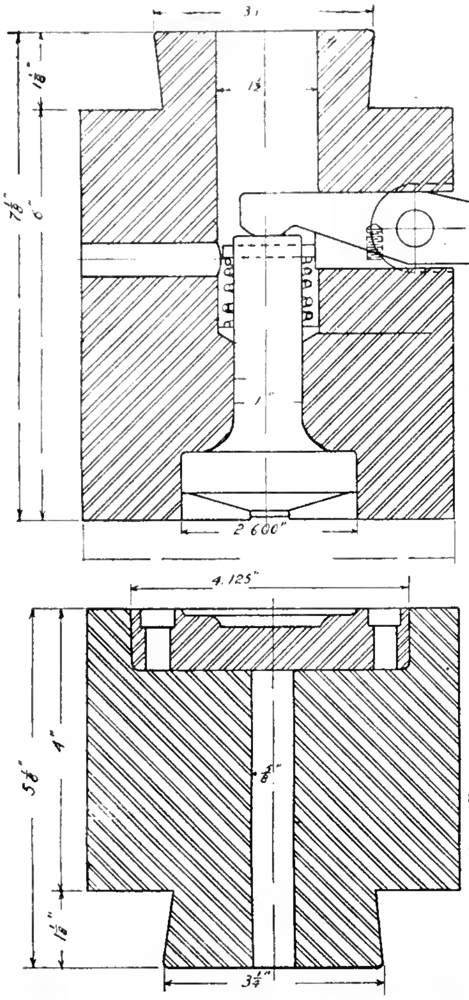
This arrangement can be made much more rigid by bridging the support as shown in Fig. 19. After the discs are screwed home, they are riveted in as shown in the centre of Fig. 19.

Finishing Base.

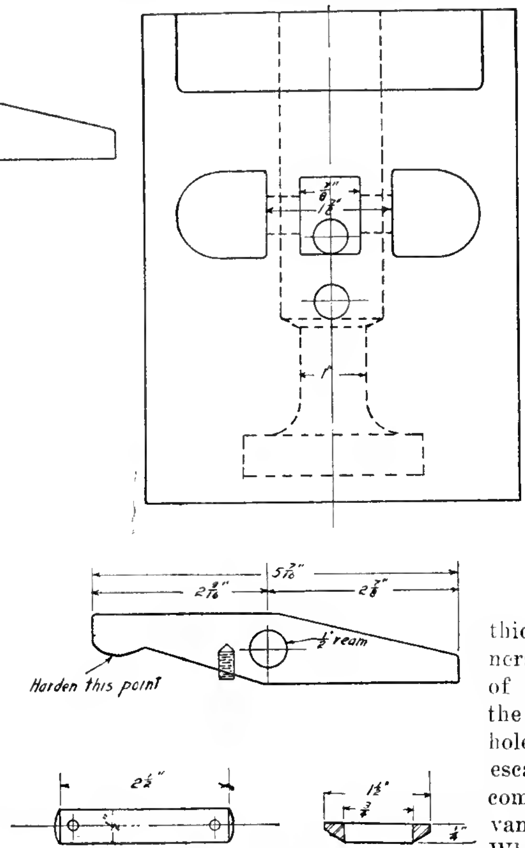
The projecting ends of the plugs are afterwards faced off on fifteen "Hall" cutting-off machines, these tools being specially adapted to this particular work.

Baking and Varnishing.

After the shells have been machined and inspected, they are ready for baking and varnishing. This operation is shown in Fig. 23. In the foreground is seen the arrangement for cleaning out the interior by means of a strong blast of air. The shells are next placed upon the hot plate shown in the background,



where they are heated to a temperature of about 400° F. The layout of this device is shown in Fig. 24. A steel plate, 7/8 of an inch thick by 4ft. by 7 ft., rests upon a wooden framework which is covered with asbestos of about ½ inch in



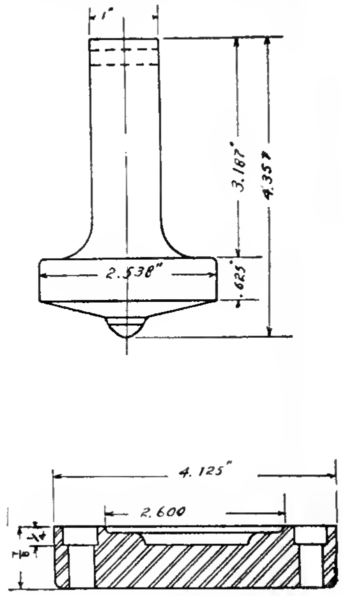


FIG. 21A. DIE BLOCKS AND DIES WITH "KICKER" FOR FORGING 18-PDR. SHRAPNEL DIAPHRAGMS.

thickness to keep the heat of the burners from attacking the wood. A row of six pipes extends the full length of the plate which is perforated with small holes from which the gas is allowed to escape and burn. As indicated the complete apparatus is covered with galvanized iron to protect the workmen. When the shell has reached the required heat, the man to the right fills the shell with varnish and then empties it into

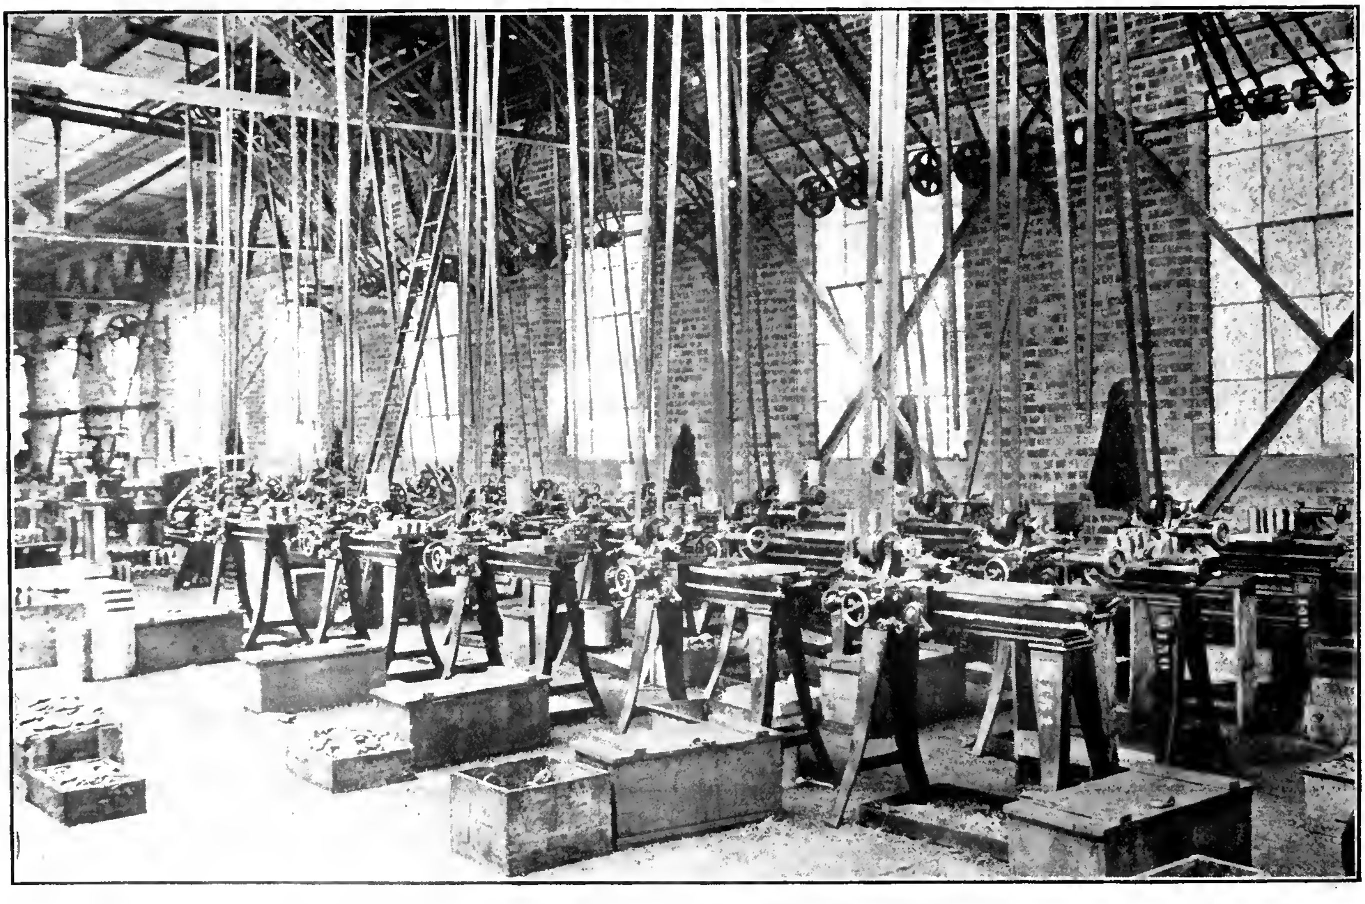

FIG. 22. GROUP OF LATHES TURNING DIAPHRAGMS FOR 3.3 SHRAPNEL SHELLS.

the next shell to be varnished, sufficient varnish adhering to the interior to leave the required coating. Heat drying immediately follows. A thin shell piece screwed into the nose serves to protect the thread from the varnish.

FIG. 23. AIR BLAST, BAKING AND VARNISHING.

Painting.

The painting is done as shown in Fig. 25, four shells being revolved in the one jig as the painting progresses. Fig. 26 shows the revolving arrangement. The shells C are placed on the piece B, this having a stem passing through the piece A which is secured to the bench. Attached to the bottom of each stem is the gear E which meshes with the intermediate gears F. Connected to the center shaft is an ordinary air motor which is supported in position by the cross piece of wood H. The same arrangement applies to the painting of the 3.3 shrapnel shells.

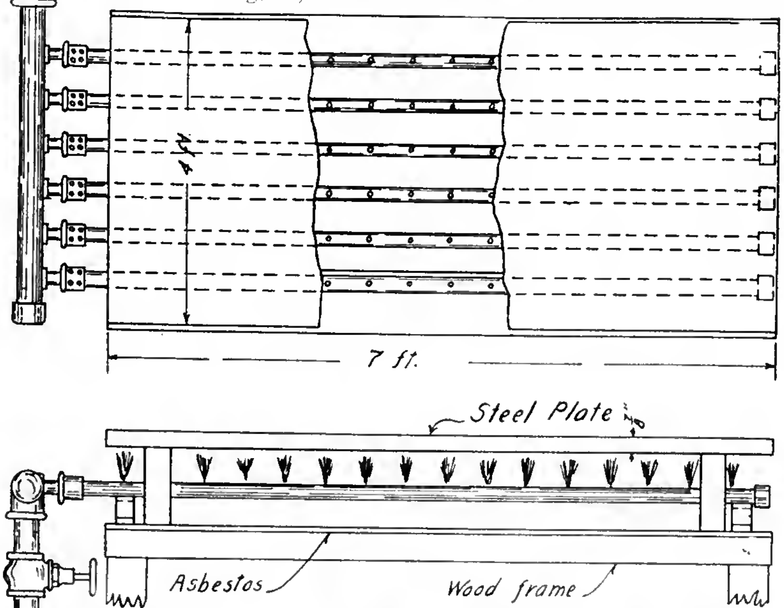

FIG. 24. HOT PLATE FOR VARNISHING.

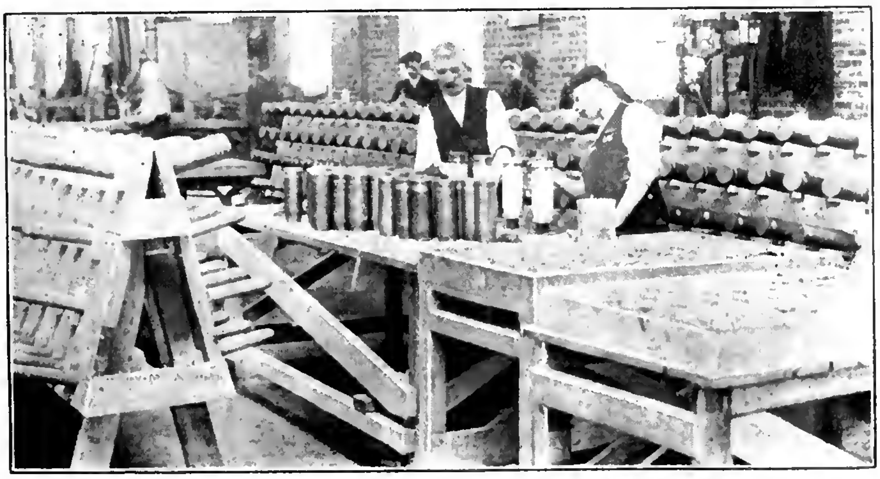

FIG. 25. PAINTING THE FINISHED SHELLS.

Shrapnel Shell Diaphragms.

The production of the diaphragm discs, which are placed inside shrapnel shells before the nose is formed, is one of the interesting features in connection with the manufacture of these projectiles. Punchings of 7-16 inch steel plate are forged to the desired shape and machined to fit the recess in the finished shell.

The punchings are placed in the Mechanical Engineering Co. oil furnace, shown in Fig. 21, and are heated and forged in the two Boomer & Boschert presses shown to the right and left of the furnace. A sketch of the forging die is shown in Fig. 21A. After being forged, they are taken upstairs and finished to the desired shape in the machines shown in Fig. 22.

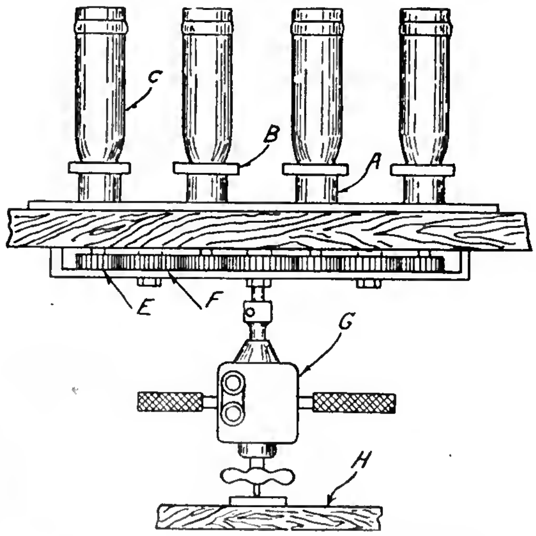

FIG. 26. PAINTING ARRANGEMENT.

When this plant is fully equipped an output of 5,000 each of 3.3 shrapnel and high explosive shells per week is expected.

The conversion of shipbuilding and marine engineering shops into shell factories proceeds apace in Great Britain, and still the demand for munitions exceeds the output. It is stated in this connection that for every soldier in the field there should be a munition worker at home, and that a battery of field artillery can use in a single day the output of 300 mechanics.

CARTRIDGE CASE COOLING CONVEYORS.

THE accompanying cuts show two special conveyors of 33 feet centres furnished by the Stephens-Adamson Mfg. Co., Aurora, Illinois, to the Metal Drawing Co., St. Catharines, Ont., for carrying red hot cartridge cases for 18-pdr. shrapnel shells from the annealing ovens to the pickling tanks prior to being re-drawn. The function of these conveyors is to afford a means whereby the cartridge cases can be cooled gradually while travelling from ovens to tanks.

Fig. 1 shows a pan of cartridge cases which have just been discharged from the annealing furnaces. These are picked off the pan singly or in pairs by means of long hand pinchers or tongs, and placed in a wire basket, which holds forty cases. The pan when empty is trucked around to the receiving end of oven ready to receive another batch of cases to be annealed. The conveyor is then put in operation and moves for a distance of two feet bringing an empty basket ready to receive its load.

Fig. 2 shows the discharge end of conveyor with basket laying in horizontal position (same as receiving end) ready for cartridge cases to be removed by hand and placed in pickling tanks for treatment.

The conveyors are spaced 14 ft. centres in line with the annealing furnaces, and between the conveyors is installed an exhauster for cooling the cartridge cases while in transit, the conveyors being started and stopped at will at either end by means of a friction clutch pulley on line shaft driving the same.

The capacity of each conveyor is approximately 1,400 shells per hour, and the time consumed between receiving and discharge end is thirty minutes, the cartridge cases emerging from conveyor thoroughly cooled. Edwin J. Banfield, Toronto, is the Ontario representative of the Stephens-Adamson Co.

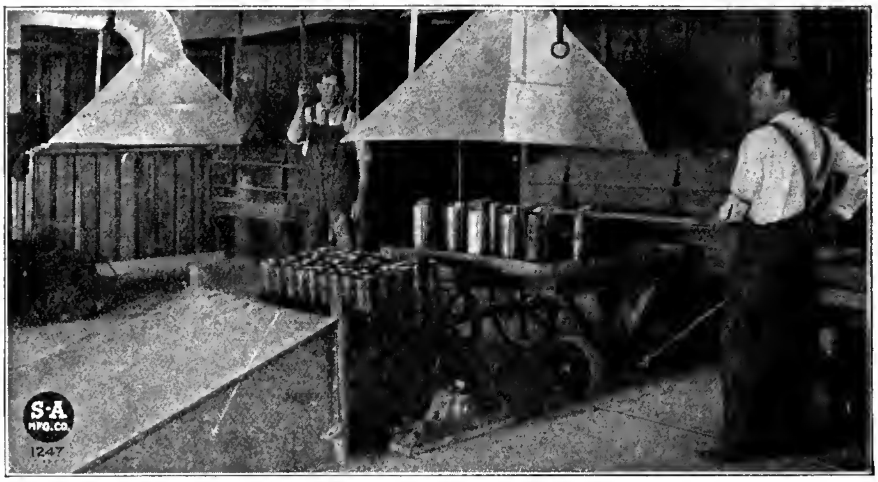

FIG. 1. CARTRIDGE CASES BEING PICKED OFF PAN FROM ANNEALING FURNACE AND LOADED INTO WIRE BASKET ON CONVEYOR.

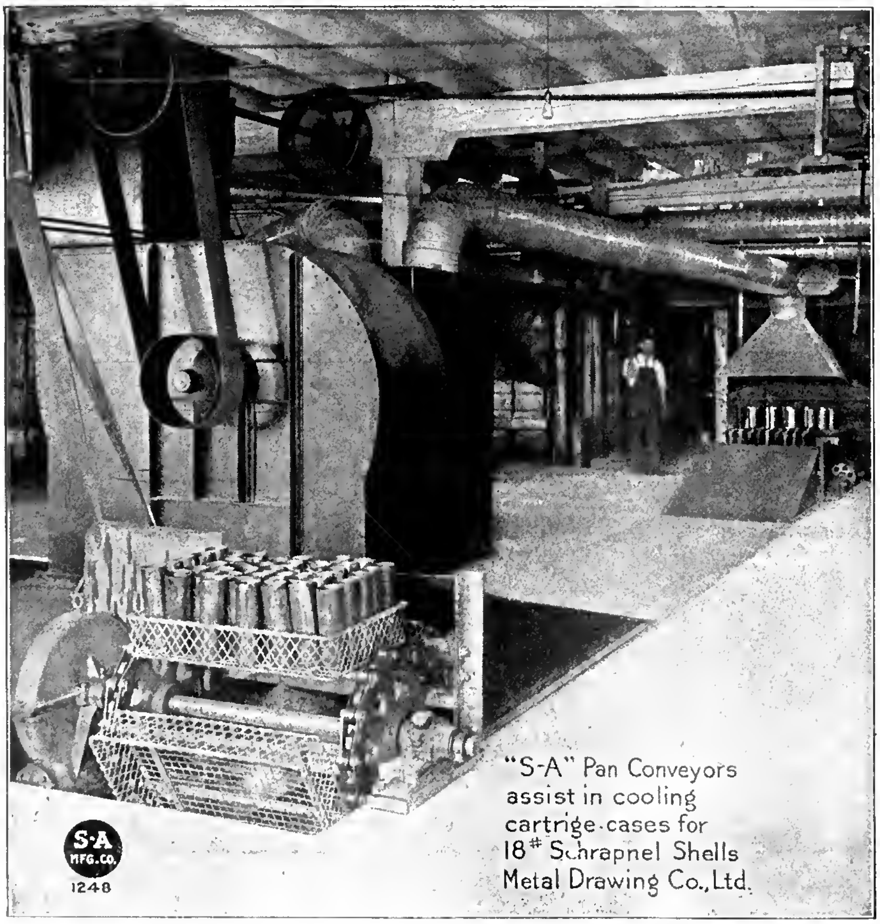

FIG. 2. DISCHARGE END OF CONVEYOR SHOWING CARTRIDGE CASES IN WIRE BASKET FOR REMOVAL TO PICKLING TANKS.

FORGING PLANT FOR 6-INCH SHELL FORGINGS.

THE cost of equipment for producing shells increases very rapidly with the size of the shell. While it is possible to extemporize to a great extent in the manufacture of 18-pdr. shrapnel and high explosive shells, the requirements of 4.5 inch shells demand more perfect machines. If the forging equipment be taken into consideration, the cost rises very rapidly. With 18-pounder shells, the forging has been done in heavy power presses or bulldozers, but 6-inch shells require a plant of a different type.

Recent estimates show that to produce 6-inch shell forgings, the following equipment is necessary. The shells are 30 inches long and the output is 30,000 per month, working 100 hours per week:

Five 450-ton vertical combined piercing and drawing presses, approximate weight 40 tons each; three 200-ton vertical cylinder pointing presses, approximate weight 8½ tons each; two 550-ton type banding presses, approximate weight 8½ tons each; three 200 brake horse-power, electrically driven, 3-throw hydraulic pumps, approximate weight 2¼ tons each; one 26-inch x 20-foot hydraulic accumulator, weight 90 tons.

A method of making a submarine periscope invisible at sea at any considerable distance is to be tested on the K. 6, now in dry dock in Brooklyn Navy Yard. The periscope has been painted in parallel stripes in various colours of the spectrum and it is calculated that the colours when refracted will be converted into a white ray.

4.5 Howitzer Shell Production in a Structural Steel Plant

Staff Article

Uncertain as to the war duration, but with the desire to bear a part in furnishing our Empire with munitions of war while maintaining its normal manufacturing equipment practically intact, the institution here described has, by the investment of a moderate amount of capital and by drawing on the skill and aptitude of its staff, succeeded in achieving a highly satisfactory degree of success in the matter of shrapnel shell quality and quantity output.

IN many cases of shell manufacture the producers were formerly engaged in branches of engineering which called for a more or less complete machine shop equipment, consequently their personnel and plant were capable of adaptation to the shell businesss, promptly and effectively.

A structural steel works such as forms the subject of this article could not be expected to enter the list of producers on equal terms with machine shop establishments. Their energies had been devoted to an entirely different class of work, involving machines, material, and operations quite foreign to the average machinist. Besides being handicapped by the nature of their previous work, they had to go into the market for tools when it was a case of taking what one could get instead of getting what one wanted.

A study of the methods and machines as developed under these conditions should be of considerable assistance to firms who are not yet advanced to the "shipping" stage. Most of our readers are now familiar with shrapnel manufacture, therefore, the points of variation will be easily noticeable.

Many special attachments are now obtainable from different machine tool builders, either for use on their own product or adaptable to any standard type of machine. It is noteworthy in the plant in question that with the exception of collapsible taps all fixtures, jigs and other appliances are the product of the shop. A consideration of the operations and the tooling equipment developed shows most creditable work by the tool room staff.

Table I. shows the sequence of operations as at present adopted.

Table I.

1—Cutting off open end only—one spur-geared constant speed cutting-off machine, built by Williams Tool Co.
2—Centering—one 10-in. single-geared drill press, built by W. F. & John Barnes.
3—Rough turn outside—one 28-in. "New Haven" engine lathe and one 28-in. "Leblond" engine lathe, both fitted with special tool equipment.
4—Rough face base—one 32-in. "American" engine lathe.
5—Bore and ream—three 24-in. "Davis" turret lathes.
6—Countersinking bevel on mouth—one 36-in. "Fosdick" radial drill.
7—Nosing—one "Hanna" pneumatic riveter.
8—Bore, face and tap nose—one 20-in. "Dreses" turret lathe.
9—Turn body and nose—one 22-in. "Hill, Clarke" engine lathe.
10—Finish internal profile of nose—one 20-in. "American" engine lathe.
11—Bore and tap recess—one "Acme" screw machine.
12—Insert plate and face-off.
13—Groove, undercut and form waved ribs—one "Whitcomb-Blaisdell" engine lathe.
14—Pressing driving bands—one three-throw "Perrin" plunger pump and banding press.
15—Turning bands—suitably equipped engine lathes.
16—Varnishing—steam-heated oven.

Reviewing the operations in rotation: The cutting off does not call for special mention, beyond the fact that the choice of a constant speed machine is justified by the small amount of tool travel due to cutting off the open end only, and leaving the facing of the base for a subsequent operation. The avoidance of friction discs and other accessories of variable speed machines is desirable in heavy work. Fig. 1 shows the detail of supporting arbor for centering shells on a small drill press. The bushing A slides on the arbor and rests on a spring B, which maintains it in a position near the top of the arbor. The spring B in turn rests upon shoulder C formed by the lower part of the arbor.

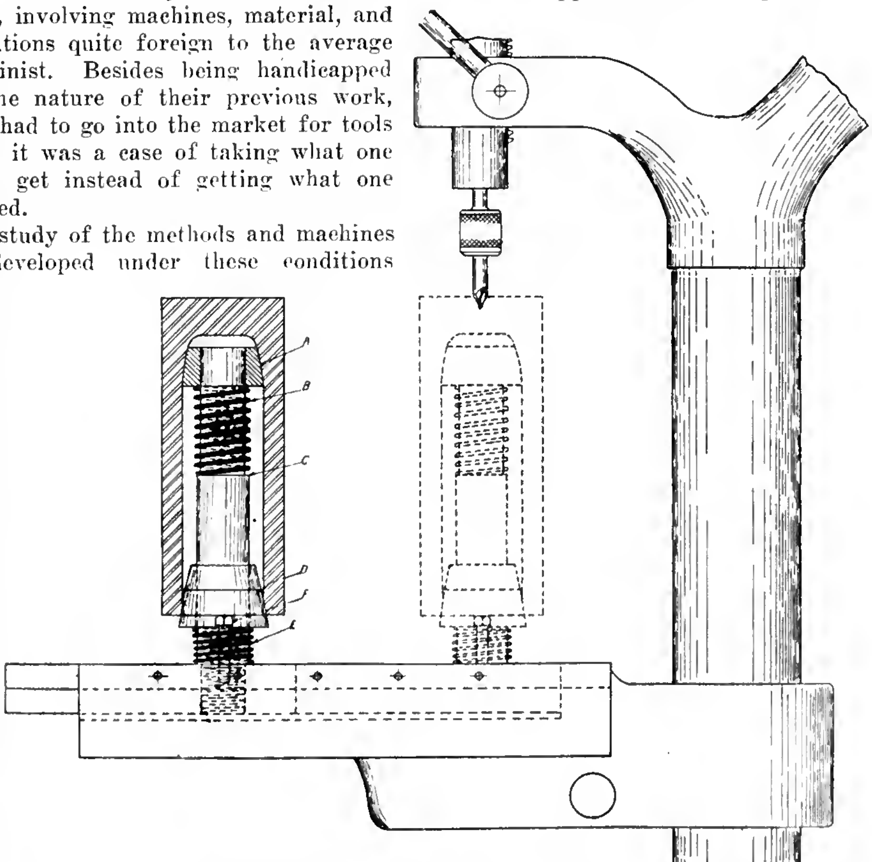

FIG. 1. CENTERING 4.5 INCH H. E. SHELL FORGINGS. DETAIL OF ARBOR.

Bushing A is made an approximate fit

for the rough bore of the forging near the base. Bushing D is a sliding fit for the lower part of the arbor, and is maintained in its highest position by spring E. Bushing D is made with a suitable taper so as to rest half way into the open end of the forging. The arbor itself is fastened to a block which slides in vees formed on the table of the drill press. When the arbor is in the outer position it is well clear of the spindle and allows the forging to be placed over it. This being done, bushing A centres itself from the rough bore near the base while the mouth of the shell is centred on conical bush D. Both of these bushings now compress the springs B and E until the weight of the forging is taken by stop pins F. By sliding the arbor to the inner position where it comes against a stop the centre of the shell is brought exactly under the centre of the drill which drills the centre hole in the usual manner.

Rough Turning.

After centering, the forgings are ready for operation (3), viz., rough turning the outside. The machines on which this is done are standard engine lathes. They are fitted with special tool boxes which carry two cutting tools spaced half the length of the shell apart from each other so that the time for the operation is halved. The tool box is of very substantial design, the tools being made of square tool steel inclined nearly to a vertical position so as to have a constant angle of clearance underneath, irrespective of the amount of top rake. The forging is driven by means of a tapered arbor with longitudinal grooves forming teeth on which the shell is driven, and held by the centre in the tail stock. This machine is shown in Fig. 2. As the amount of stock to be removed from the forging is just over one-quarter of an inch on the diameter, the capacity of these machines is limited by the ability of the tool steel to stand up under a high speed rather than by the amount of power required to remove the material. A speed of 60 feet per minute is easily maintained by the steel at present used.

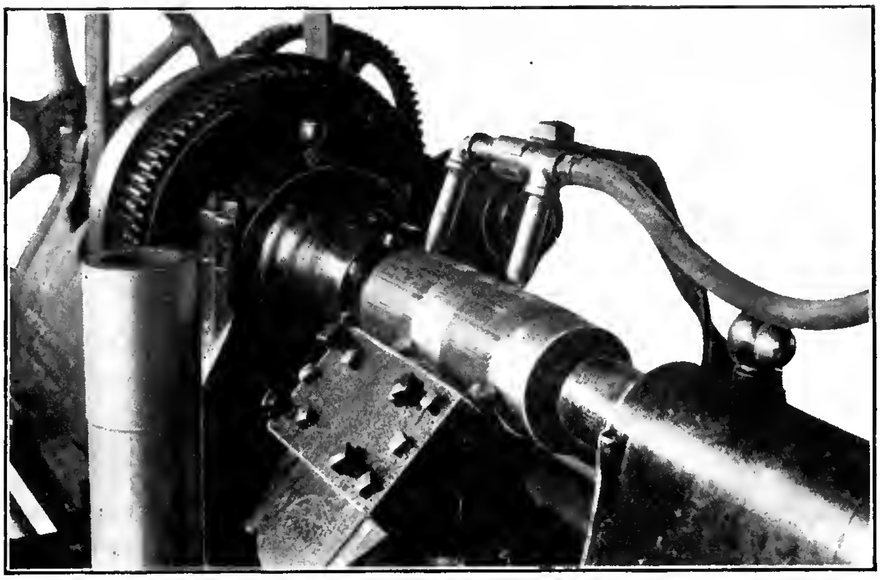

FIG. 2. ROUGH TURNING 4.5 H. E. SHELLS.

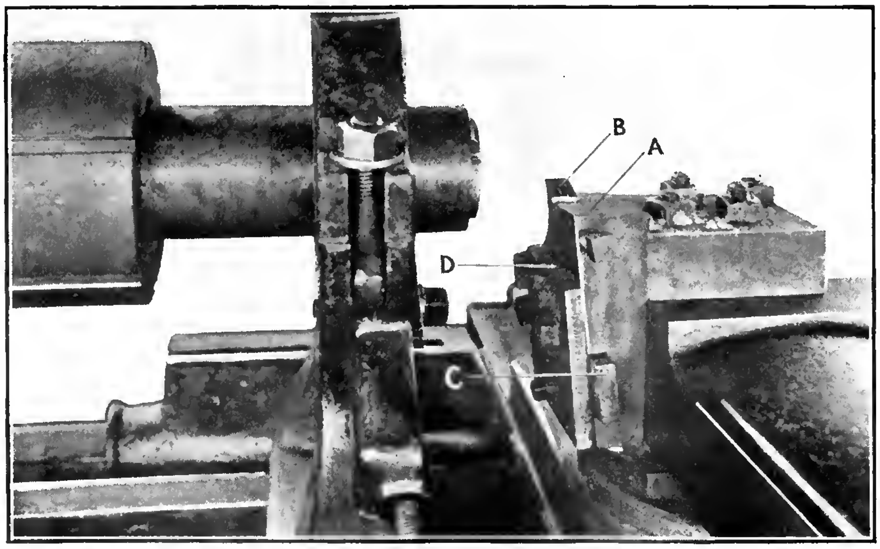

FIG. 3. OVERHUNG TOOL HOLDER FACING-OFF SHELL BASE.

The body of the rough turned shell is now of two diameters, the half of the shell next the base having just enough left on to take a final cut at a later stage, while the half next the mouth of the shell is left somewhat larger so as to have a safe margin of stock to allow for any variation in the profile of the nose after nosing-in.

The base of the shell must now be faced off to the proper thickness. Considerable variation is liable to occur in the forgings at this point, and in centering the forgings in operation (2), care must be taken to drill the center holes to a uniform depth, measured from the inside. The probability of excessive stock having to be removed at this point calls for a machine of ample capacity. The machine provided in this case is satisfactory.

An Interesting Tool Holder.

A feature of the equipment is the overhung side cutting tool holder with wedge adjustment for the cutting tool. This is clearly shown in Fig. 3. An L-shaped block is clamped on the tool box of the lathe, with one arm hanging downwards on the left side. A slot is provided in this overhanging arm to take the square tool B, which is inclined slightly from the vertical for clearance. The tool is adjusted vertically by means of the flat wedge or cotter C., the end of which can be observed in the illustration. A securely fastened side plate D holds tool and cotter in position. During this operation the shell is held in a collect chuck by the nose, while the base end revolves in the steady rest.

Boring the parallel portion of the inside, and reaming the tapering portion where the sides meet the bottom constitute the fifth operation. Heavy turret lathes are employed, having three boring bars fitted with a single cutter bar for the parallel portion of bore, and a roughing and finishing reamer for the tapered portion. The layout of the turret is shown in Fig. 4, from which it will be observed that the bars are fastened to the turret faces by flanges, into which the bars are tightly screwed and keyed. Holes on the top side of the flange communicate with a central hole which emerges at the point of the bar and allows the use of a copious supply of cutting compound at the proper point. The compound is supplied through a hose pipe with a nozzle to fit the holes in the flanges, and is changed round to each flange as its bar is brought into operation.

Impromptu Nosing Press.

A radial drill for which suitable employment had not been found was utilized for shaping the mouth of the nose preparatory to nosing. The section of the shell before and after nosing is shown in Fig. 9. The exact outline required before nosing has been the subject of considerable experiment by most makers, and the shape shown here will be useful for comparison with present and proposed outlines. The cutter is shown in Fig. 5. This is of the flat double-edged type, and is provided with a substantial pilot, which enables the full power of the drilling machine to be applied to the cutter without excessive vibration or chatter.

While to the casual observer nosing seems one of the simplest operations, there is probably a greater variety of machines used in this than in any other operation. In utilizing an existing pnuematic riveter, this firm has shown a further example of adaptation which is interesting. The machine is of the fixed horizontal gap type, with a vertical ram actuated by a compressed air cylinder operating toggle gear on the upper part of the frame. This nosing press is shown in Fig. 6, also the home-made furnace for heating the noses.

This furnace consists of an ordinary grate made of iron rods, surmounted by a semi-circular brick arch, well strapped down to the base. Three openings are provided for the graphite crucibles, which are supported on brick blocks, resting on the grate bars. A coke fire is used, which surrounds the crucibles on all sides. No chimney is required, the draft being maintained by a gentle pressure of air from the air line, the products of combustion emerging through the space around the top edge of the crucibles.

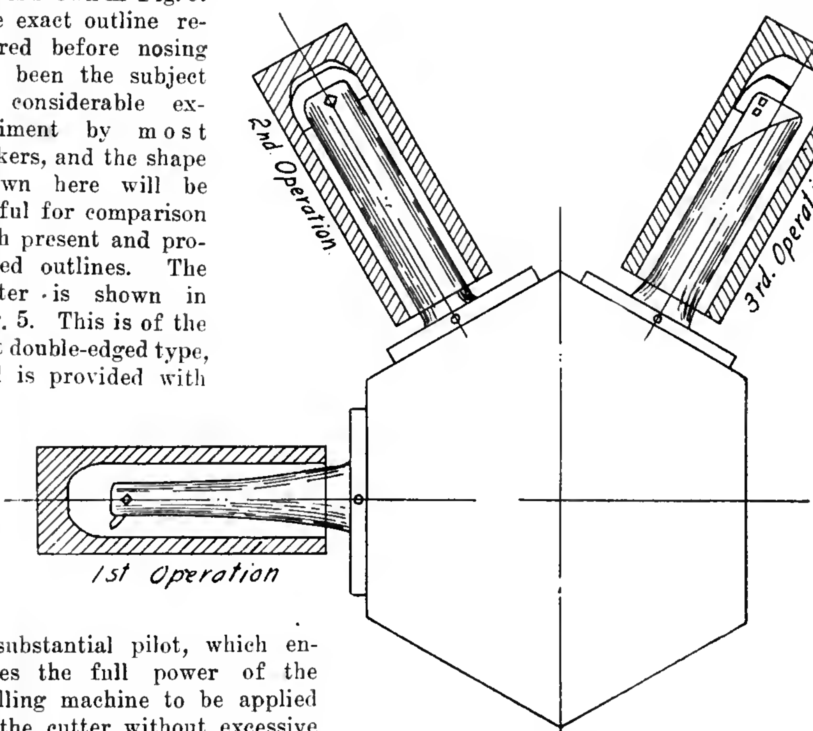

FIG. 4. LAYOUT OF TOOLS ON "DAVISS" TURRET LATHE.

Such an arrangement would be objectionable in some shops, but in a spacious well ventilated building, such as is shown here, it is quite suitable. The work is all that can be desired, the resultant hole being parallel and close to size, while the profile also approximates very closely to the finished outline. During the operation, the shell is securely held in an open-sided vise-block, with a swing gate in front, which is tightened up by a lever with a cam end on the boss.

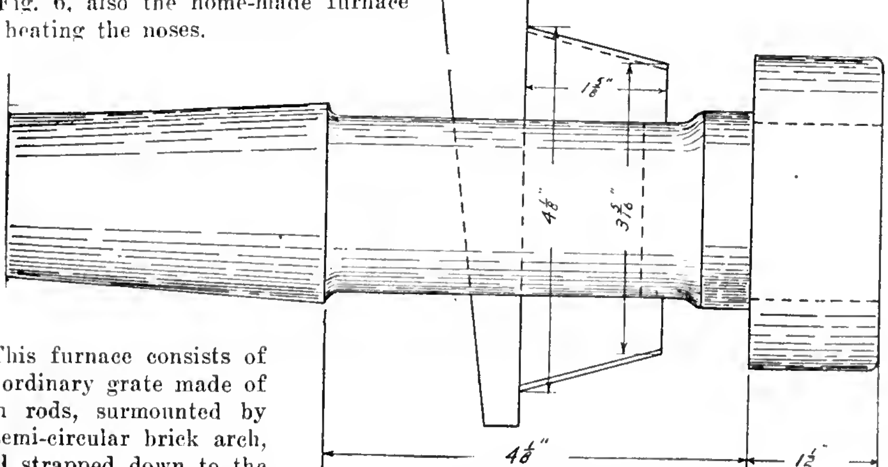

FIG. 5. CUTTER FOR BEVELLING INSIDE OF NOSE BEFORE CLOSING.

The eighth operation is performed with the shell chucked by the base and supported in a steady rest. A turret lathe is employed, two faces only being used. One is fitted with a boring bar having a cutter of suitable shape which bores the hole and faces the end of the nose. The other face of the turret carries a Murchey collapsing tap which threads the hole.

Profile Turning.

In the next operation, the shell assumes its final size and shape on the outside. The arrangement of the profiling

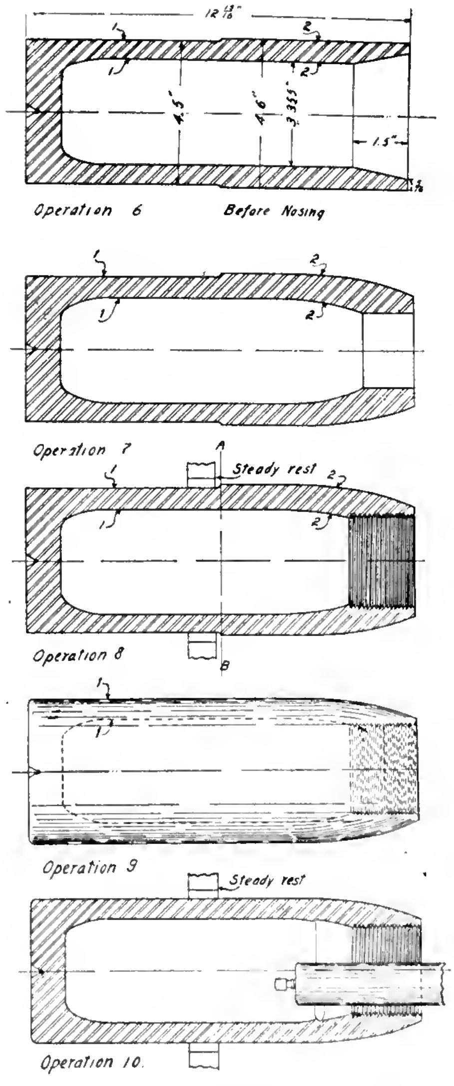

FIG. 9. ILLUSTRATING OPERATIONS 6, 7, 8, 9 AND 10.

attachment will be understood from Fig. 7. A supporting bar is fixed to two supporting blocks which are clamped over the front vees of the lathe bed at suitable points. A roller is mounted on the side of the cross slide. Two powerful springs pull the cross slide forward, and keep the roller in contact with the profile bar which is mounted on the supporting bar.

The means adopted for driving the shell is simple and efficient. At this stage of manufacture the shell has had

its overall length finally determined, the nose having been machined in relation to the base. In the operation under discussion, the shell is located by bringing the finished end of the nose in contact with a surface which has a fixed location in reference to the profile templet, so that each shell will occupy the same position in reference to the templet and insure a uniform thickness of wall in the nose.

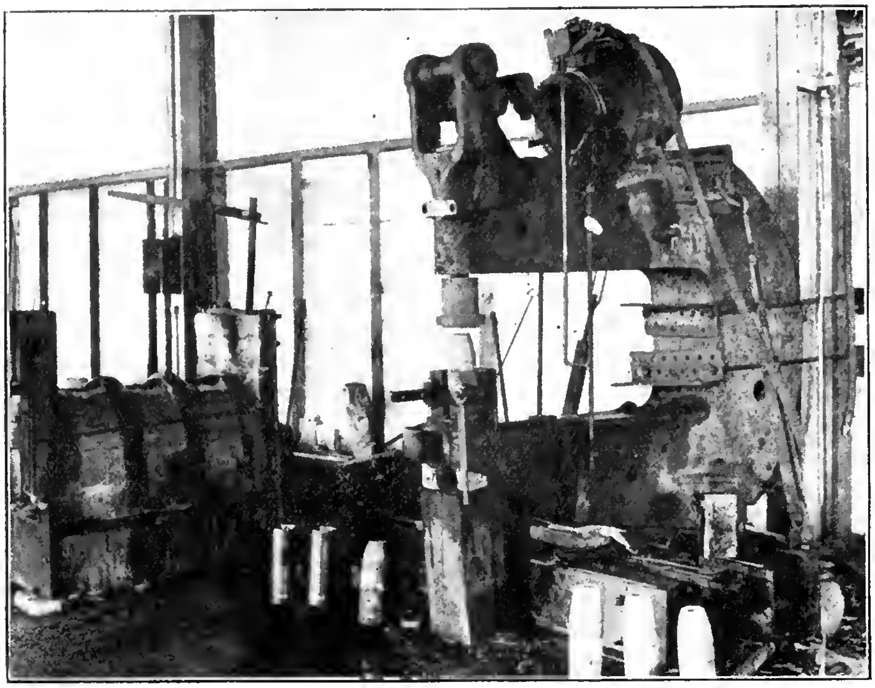

FIG. 6. PNEUMATIC RIVETER USED FOR NOSING 4.5 INCH H. E. SHELLS.

Fig. 8 shows the arrangement of driving plate and method of locating it accurately again, after it has been slackened off to allow removal of shell. A cast iron arbor, A, is threaded to fit the nose of lathe spindles. Diameter B, is machined to fit the index plate C, which carries a spring index pin or plunger D. This plate C, is secured in position by a set screw. The nose of arbor A has a left hand thread 2.6 in. diameter, which fits the threaded portion of hole in driving plate E.

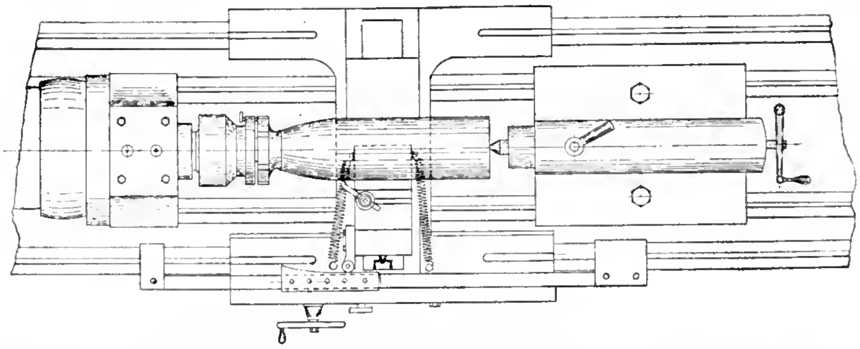

FIG. 7. PROFILE ATTACHMENT FOR TURNING OUTSIDE OF 4.5 INCH H. E. SHELL ON ENGINE LATHE.

The point of the arbor is provided with a hardened steel cap F, 2.5 in. diameter, which is threaded to fit the nose of shell. The unthreaded portion of the arbor between the left and right hand thread is made a good close fit for the unthreaded portion of hole in driving plate E.

In assembling the device, a spot is recessed on back of driving plate E. to receive plunger D. plate E being located on arbor A so that a suitable amount of right hand thread will be available for receiving the nose of shell. Index plate C is now securely fastened in place. A shell is now screwed on to the end of the arbor till it tightens up against edge of driving plate E. The left hand thread automatically locks the parts together, and any tendency of the driving plate E to revolve, simply causes the left hand thread to wedge the driving plate tighter against the nose of the shell.

When the shell has been machined, the spring plunger D, is withdrawn from the driving plate E, which is now slackened back by means of a wrench, suitable slots being provided. After the shell has been screwed off the arbor, the driving plate E is turned back to its original position and locked by plunger E, thus insuring the next shell occupying the same location in regard to the profile copy.

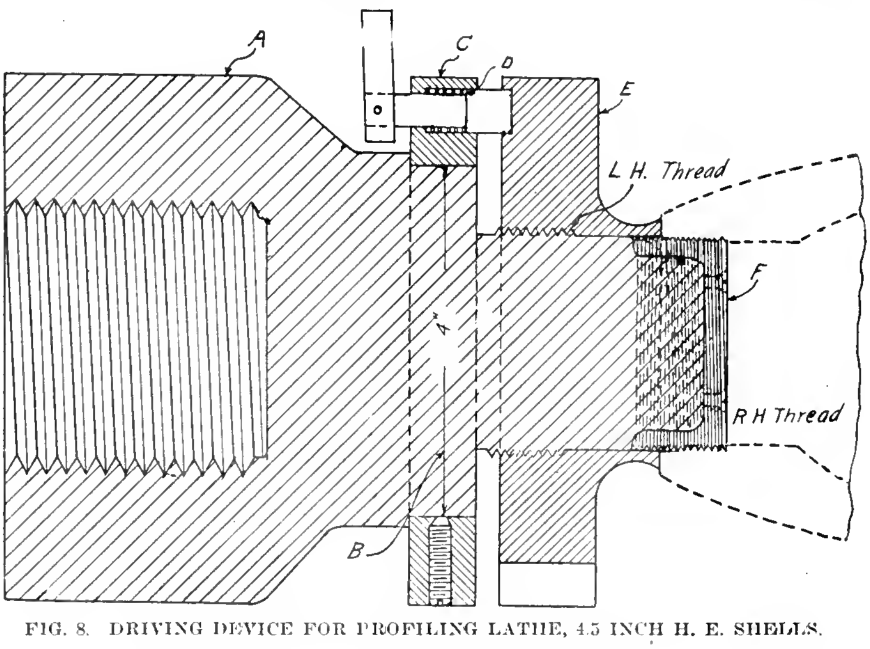

FIG. 8. DRIVING DEVICE FOR PROFILING LATHE, 4.5 INCH H. E. SHELLS.

Operation 10 consists of machining the internal profile of the nose. This is a straight-forward job due to the fact that the curve is of a single radius thereby allowing the cross slide to be connected by a radius link of the specified length to a fixed point at the rear of machine. By fixing the line of this point at the correct distance back from the nose of the shell the internal curve is reproduced.

Interdependence of Operations.

Operations 7, 8, 9 and 10 should be considered carefully because the condition of the shell after operation 10 is entirely dependent on the degree of accuracy with which the previous operations have been performed. Fig. 9 shows the shell during these operations, from which it will be observed that be-

fore nosing, surfaces (1) are concentric with each other, and also with surfaces (2). After nosing, surfaces (2) may or may not be concentric with surfaces (1), while surfaces (1) will still be concentric with each other. In operation (8), therefore, care must be taken to see that the steady rest is sufficiently far back from the beginning of the curve so that the body of the shell from the base up to line A.B. is running true.

As the bore of the shell at this point is concentric with the outside, the thread which is now formed in the nose will be concentric with the parallel part of the bore. By working with a center plug in the nose for operation (9), the outline of the body is carried forward to the end of the nose in accurate relation to the thread. Therefore, when the shell is supported on the outside for operation (10), the parallel portion of the bore will still be running true as at the start. The action of the boring cutter is now to true up the inner wall of the nose making the wall concentric and of even thickness. Unless the sequence of operations at this stage be carefully planned and accurately carried out, the resultant product may easily get out of truth with objectionable effects on the balance of the shell when fired from a gun.

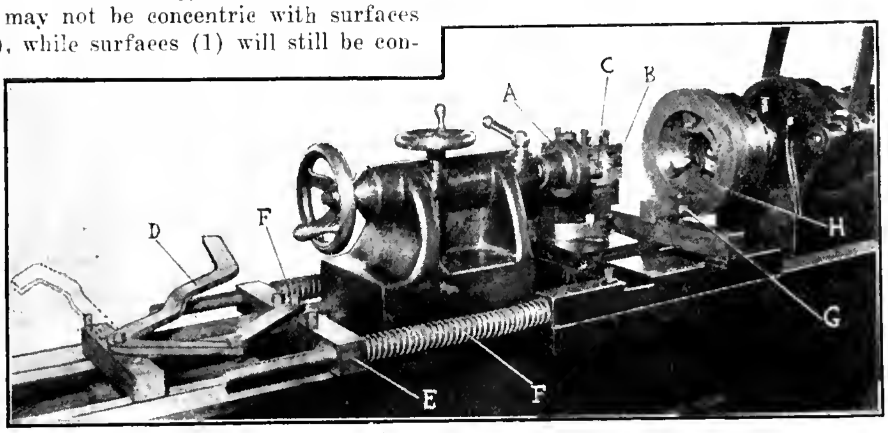

FIG. 10. WAVING EQUIPMENT ON ENGINE LATHE FOR 4.5 INCH H. E. SHELLS.

Boring and tapping the recess in the base is done on a screw machine using a collet chuck and steady rest. "Murchey" collapsing taps perform this threading job in a satisfactory manner. The plug is next tightened home, the ends of joints riveted and then faced off in the usual way.

Efficient Waving Method.

Forming the groove, undercutting the sides, and waving the threads are done in an ordinary engine lathe which has been fitted with a well-designed combination tool box, and the now familiar cam ring on the chuck. Fig. 10 gives a good idea of the substantial nature of the equipment. The base of the shell is supported in a cup centre A, and is driven by a plug center, in the nose-end.

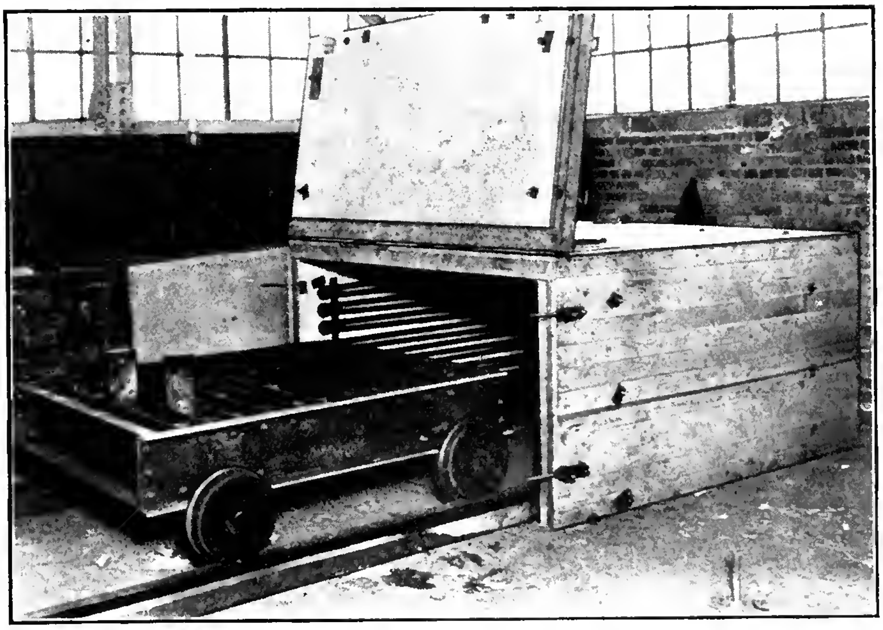

FIG. 11. STEAM HEATED BAKING OVEN.

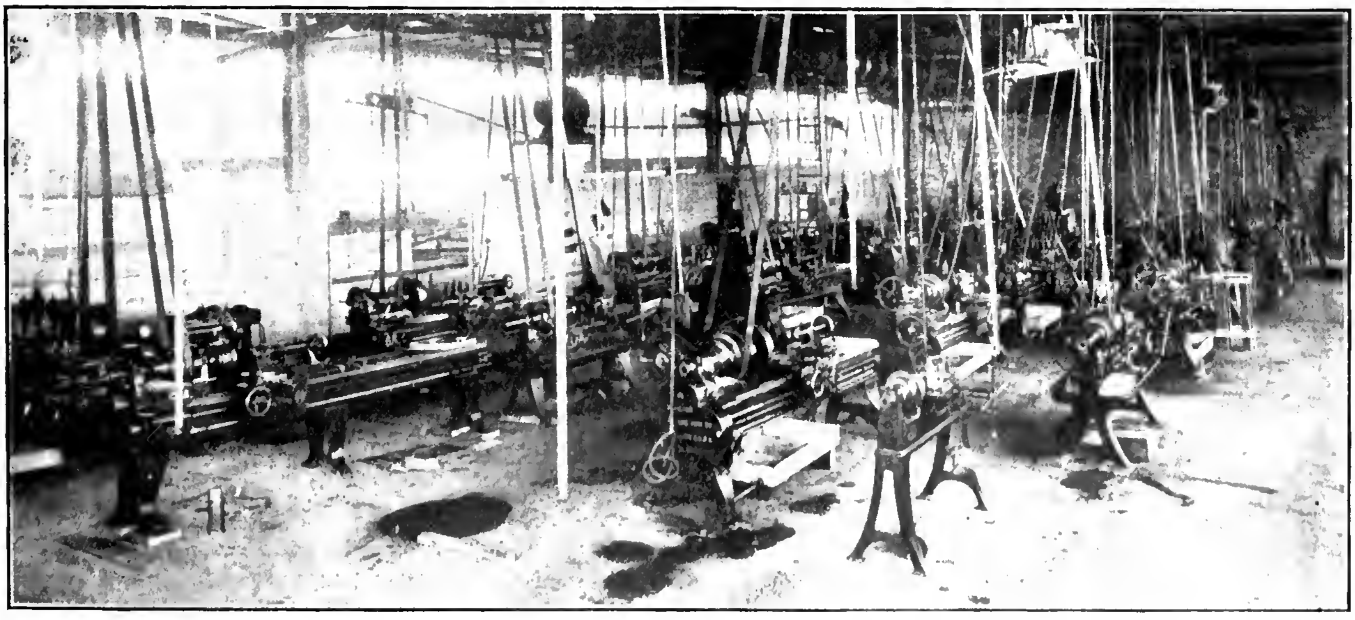

FIG. 12. GENERAL VIEW OF SHELL DEPARTMENT.

Tool B is formed of two parts so that if one corner is broken off in undercutting the whole tool is not scrapped, but just the broken half. In operation, tool B is fed straight into the shell to the required depth and then moved to each side to form the undercut.

A relieved portion in front of the tool leaves the proper amount of material which is formed into waved ribs or threads by tool C. After tool B has operated, the toggle joint is straightened out by moving hand lever D to position shown by dotted lines, causing crossbar E to compress the springs F and maintain the roller G. in contact with cam plate H, the revolving of which imparts the reciprocating motion to tool B necessary to form the required number of waves per revolution.

The remaining operations of banding, band turning and varnishing the interior of the shell are performed in conventional manners and complete the making of the shell to the point where it is ready to be fixed. The thorough manner in which the work has been planned and carried out and the modern methods employed as evidenced by the use of "Cooper-Hewitt" mercury vapor lamps for lighting, and "Chapman" transfer trucks for handling material, show that the firm in line with other Canadian shell makers is fully determined to supply shells to the utmost capacity of the plant, and of satisfactory quality.

SOCKET DRIVING MACHINE.

THE use of a drill press instead of a hand wrench for driving home the brass socket in the nose of shrapnel shells effects a double saving. In the first place, a workman can maintain a higher rate of output for an indefinite period with far less fatigue; and, secondly, the tool employed can be used to reduce the amount of work necessary on subsequent operations. A large drill press, Fig. 1, with powerful double gearing, was used for this work. The shell (a) is held sesurely in the hinged vise (b) fastened to the table of the machine. A hollow mill (c) is fixed in the spindle, and, when fed down on top of the socket (d), the inserted teeth dig into the metal and take hold firmly.

Continued pressure on the feed lever screws the socket home, the point of tightening being indicated by the teeth of the cutter beginning to cut up the edge of the socket. The cutter is shown in Fig. 2, from which it will be noted that, when suitably designed and carefully operated, it does the work of a roughing tool for machining the outside edge of the socket. Owing to the close limits on the finished sizes of sockets, it is hardly practicable to complete the work at this point.

The heavy dotted lines in Fig. 2 show the outline of the rough socket, while the lighter dotted lines indicate the amount

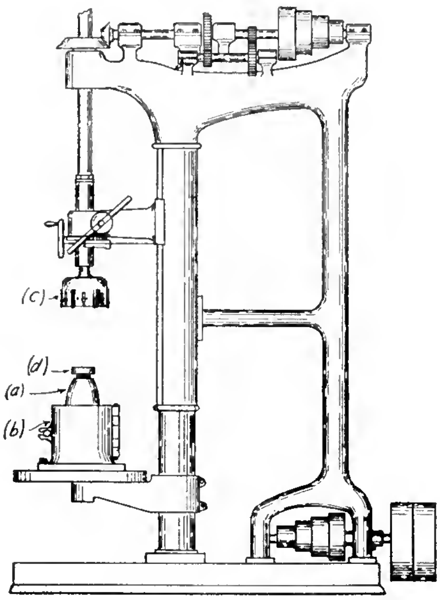

FIG. 1. TIGHTENING SHELL SOCKETS ON A DRILL PRESS.

left on for subsequent machining in lathe.

THE TEST OF WEAPONS

"IT is now the first birthday of the war, and as we look back the affairs of peace appear distant, vague and unreal. Once more the old world accepts violence and

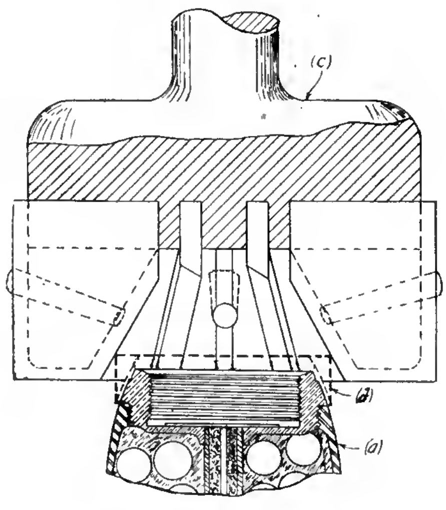

FIG. 2. HOLLOW MILL FOR SOCKET TIGHTENING MACHINE.

danger as its native element and puts everything to the test of weapons, and, if we may judge from the experience of a year, this great test shows mankind much as it always was and war much at it has always been. All the fine professions of peace have fallen away like a cloak, and nations fight after their customs of a thousand years.

"It may be food for the cynical philosopher to recollect that only eight years ago the delegates gathered at The Hague were full of busy ideas for making war humane and for civilizing violence, and expressing fine sentiments about 'the luminous star of peace' and the 'progress of human solidarity.'

"To-day the German public have made a song about the sinking of the Lusitania. In 1907 the Baron Marschall von Bieberstein was telling an admiring audience that 'the principles of humanity will be the surest guides for the conduct of seamen' and that 'the officers of the German navy—I say it with a high voice —will always fulfil in the strictest manner the duties which flow from the unwritten law of humanity and civilization.'

"War reveals nations and men in their true colors: it throws a searching light upon these fine professions, and it proves among other things that Germans at heart are much as they were in the time of Frederick Barbarossa, and that war is in its nature essentially the same as it was in the days of Rome."—Morning Post.

CANADA'S GAS AND OIL RESOURCES.

THE Mines Department, under the direction of Dr. Eugene Haanel, has completed a comprehensive and exhaustive investigation of the oil and gas resources of the Dominion, and it will be issued shortly in book form. The work of investigation has been carried on for the past year or so by a field survey staff under Mr. Clapp, one of the ablest petroleum experts of the United States. The Alberta oil fields has been thoroughly gone over and, while no large producing wells have yet been developed, promising indications have been found of the existence of petroleum in several districts in the Province.

A considerable portion of the report deals with the commercial possibilities of the development of the extensive and rich oil shale deposits of New Brunswick. If these deposits are exploited it is believed that a great industry can be built up, and a substitute found in Canada for the large quantities of petroleum and its derivatives now annually imported from the United States.

So important are these deposits and so great is the market for petroleum products in Canada, that the Federal Government has provided for a bounty of 1½ cents per gallon on oil recovered from oil shales in Canada. The distillation of oil shales in Scotland has been for many years a successful and flourishing industry. New Brunswick shales are on the average richer than the Scotch shales.

The total domestic production of petroleum is now under eight million gallons, while last year imports of gasoline totalled 27,451,379 gallons, and of petroleum in other forms over 200,000,000 gallons.

Why Steel is the Most Suitable Material for Shells

By J. M. W.

The exclusive use of steel for shell casings has occasioned inquiry by ironfounders into the possibility of cast iron being used as well. While the features of the case which have been brought to light by the discussion are so greatly in favor of steel, it must not be forgotten that steel is not perfect, and that any relaxation of stringent inspection, such as exists at present might be productive of results which must be avoided at any cost.

OCCASIONAL reports, chiefly from Belgium, that the Germans were using cast iron shells, have given rise to discussions on the merits of forged steel and cast iron as materials for shell bodies.

A momentary consideration of the requirements which must be met by either shrapnel or explosive shells is sufficient to make it obvious even to the lay mind why cast iron is quite unsuited for shell bodies except under extreme conditions such as now seem most unlikely to arise so far as the Allies are concerned. The purpose of shrapnel is to destroy men; the purpose of lyddite and other high explosive shells is to destroy the defences of the enemy so that infantry may attack. Entrenchments, fortifications, entanglements and other devices for defence are of such an effective nature that they must be literally blasted off the face of the earth before the opposing infantry can get into contact with each other. A hail of leaden bullets from shrapnel shell, no matter how fierce, has little or no effect on modern field works, consequently a copious stream of explosive shells must be distributed over the desired area so as to render the success of an infantry attack reasonably certain. Explosive shells which burst on contact may be used with delayed fuses, which allow a suitable space of time for the shell to sink into earth works to a desired depth, when the explosion of the charge resembles that of a mine. The immense hollows in the ground formed by the large siege guns firing half a ton of explosive are sufficient evidence of the power of high explosive ammunition. The disastrous results which would ensue from such an occurrence taking place in the barrel of a gun render necessary the absolute soundness of shell forgings, whether shrapnel or explosive.

Absolutely Safe Guns.

The absolute strength and safety of modern guns has been a wonder and mystery to the majority of laymen for many years; consequently the guns themselves have been discussed much more frequently than has the ammunition until the outbreak of hostilities.

Given good average material such as is procurable in the open market at the present moment, a good engineering education, and a high class engineering plant— and any resourceful man will produce a formidable gun with his personal experience and skill. The knowledge of ammunition manufacture, however, has for obvious reasons never been so widespread and available as that of guns. Even now with all their experience in shell work many producers have still to develop that patriotic interest in their product which is necessary to make them appreciate the strict inspection, and which would cause many so-called hardships to be viewed in their true light of precautions instead of being looked upon as hindrances to profit accumulation.

Rigid Inspection for Shells.

A true appreciation of the painstaking care and watchful economy which is necessary in producing shells at the present moment can only be obtained by a close study of the entire process from the time the iron ore enters the furnace until it leaves the muzzle of the gun as a shell. While the actual composition of the steel is decided on and controlled by a limited number of individuals, the mechanical and thermal treatment of the material is being performed by thousands of individuals, the majority of whom endeavor to effect every possible economy in time and material. That considerable economy in material has been accomplished is evident from published results obtained by a leading English metallurgist. Losses of 40 per cent. have been reduced to 15 per cent. with very little increase in cost, and no decrease in quality. The amount of labor lost on partly machined shrapnel forgings has been quite an item, but if shell makers calmly considered the matter from the steel makers point of view, they would not be so disposed to condemn offhand a product which represents the application of so much specialized knowledge and labor.

Steel Maker's Troubles.

The steel maker is not desirous of losing the profit as well as the actual cost of shell forgings which develop defects in course of machining. Government and personal inspection of material in all stages of manufacture is planned and carried out with the object of insuring perfect material and workmanship.

The results of Sir Robert Hadfield's investigations are of prime importance at this time. Steel which has been cast in ingots by ordinary methods may appear perfectly sound while not actually so—it may be rolled into billets—it may be forged into shells—and at all stages up to heat treating it may pass all physical tests satisfactorily with the one possible exception of an examination of the microstructure. After an ingot is cast, it is not again heated to a high enough temperature to cause the removal of piping defects, consequently the lack of what may be termed "cohesive density" persists in the metal till such time as it is finally heat treated.

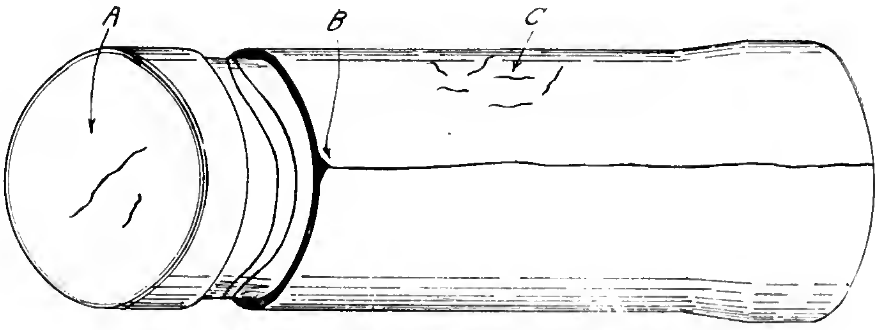

FIG. 1. DEFECTS IN SHELL FORGINGS.

When Defects Appear.

At this stage of manufacture hitherto unnoticed defects in shrapnel forgings, occasionally begin to appear. Flaws of various kinds become quite evident, although the most careful inspection before heat treating failed to reveal the slightest evidence. This trouble has caused considerable loss to both steel works and manufacturers, and the fact that it has occurred in spite of all inspection, etc., would indicate that the

steel makers are continually confronted with a serious problem. The hypotheses which the writer advances in explanation of well-known and recognized defects in shell forgings are based on personal experience in producing many thousands of shells and the conclusions arrived at are offered to manufacturers in the hope that a clearer knowledge of their cause may assist in timely detection and, ultimately, their complete elimination.

In Fig. 1 is shown a shrapnel shell with three distinct flaws, which are due to three entirely different causes. At A is indicated what is perhaps the commonest flaw. One or more cracks may open up and become visible after the shell is hardened. They may be only one-eighth inch long, or they may be one inch and eight. They may be less than one sixty-fourth inch wide, or they may be one-sixteenth inch. While most parties who have experienced this trouble seem agreed that it is developed in forging, there has not been advanced, so far as the writer is aware, any definite theory which satisfactorily accounts for their occurrence.

A Crack Theory.

It would seem not improbable that these cracks are formed when a certain combination of circumstances occurs in the course of forging operations. In starting up forging after say a week-end stoppage, the drawing punch and dies would be well cooled down, while some pierced billets might be soaking at a high heat. The combination of the cold punch inside, and cold dies outside would chill the walls of the forgings much more quickly than after running steadily for some time. The probability of an extra long billet would call for extra power, causing excessive tension in the metal on the outer layers of the base, which as suggested might possibly be at a rather high heat. While a rupture might take place at this time, it would not weld together again, but the close contact of the surfaces due to shrinkage would conceal the defect until the tension induced in the outer layers by their sudden contraction when quenched, would open them sufficiently to make their presence noticeable.

Forgings, in which the thickness of the base was well oversize, would be more or less immune from this trouble, not only because the extra metal would provide increased resistance to rupture while passing through the drawing die, but also because the extra metal is removed from the outside of the bore more conveniently than from the inside. Even if there were any slight cracks, in spite of the thicker metal in the base, they would in all probability be removed in facing the base of the shell to the required thickness.

Other conditions under which they would occur would be when the forging shop was working too closely to the minimum thickness of base. This would be most likely to happen when the forge shop was getting low on material and endeavoring to work in billets which might be a trifle undersize.

Neglect to clean out the piercing die also causes trouble through scale remaining on the bottom and getting pressed into the base. Shells have been observed with quite large defects from this circumstance, the cavities caused by the scale or other foreign matter, sometimes extending completely through the base.

Flaws Due to Rolling.

At B, Fig. 1, is indicated a flaw which occurs previous to forging. In the particular shell referred to, this flaw extended from the nose to the driving band groove. About 1-64 inch in width it could be felt distinctly with the finger nail, and, where it terminated at the driving band groove, it had broken away on either side leaving a scaley surface exposed. While at first sight it might be considered due to piping, the fact that it was only 1-16 inch deep, and did not extend over the base, would indicate rather the presence of some foreign substance or material which got worked into the bar during rolling operations, the end of the affected part happening to terminate at the groove as described.

Flaws of this kind are not dangerous in the sense of being concealed or difficult of detection. Had there been a smaller amount of foreign matter rolled into the bar, it would have been entirely removed in machining, but an internal flaw due to lack of homogeneity in the ingot could quite well remain undetected at all stages of the work.

Fissures.

At C, Fig. 1, are indicated a number of minute hair-like cracks or fissures from one-quarter to three-quarters of an inch in length. In some particular makes of forgings these fissures would be quite numerous. Their behavior was similar to flaws A, with the difference that they were more noticeable when the shells were ground instead of turned. At one period in the business, considerable trouble was experienced with hard streaks which were attributed to segregation of manganese. While opportunity did not afford full investigation at the time, the conclusion was accepted as probable.

The matter of fissures in shrapnel shells has been the subject of recent discussion in England, the theory advanced being that regions of low carbon and high phosphorus resulted in layers of different hardness. The low carbon layers being more elastic would accommodate themselves to strains brought about by quenching, while the high phosphorus layers owing to their different behaviour, would be subject to local strains which might develop in the form of fissures such as have been observed.

The fact that defects such as these mentioned can, and do occur in the handling of steel forgings, renders it obvious even to the lay mind, that the use of any material which is less reliable than steel, can only be justified by the exigencies of the situation.

Regarding Cast Iron.

The most that can be said for cast iron is that it is better than nothing. The almost entire absence of elongation results in such brittleness that in order to be absolutely safe, a cast iron shell would have walls so thick that the number of bullets contained would be so greatly reduced that the killing powers of the shell would be negligible. The probability of blow holes in the walls would disturb the balance of the shell during flight so as to destroy all accuracy of fire. The presence of cast iron shells on a modern battlefield indicates two possible contingencies:—either the demand for shells is so abnormal that a sufficient amount of raw material can not be obtained, or else the supply of steel is so much below normal that the normal consumption of shells cannot be met.

The inference is largely a matter of degree, but the results cannot be other than favorable to the cause of the Allies.

MUNITIONS INVENTION COMMITTEE

THE Minister of Munitions has constituted a Munitions Inventions Branch of the Ministry, and has appointed as Comptroller E. W. Moir, M. Inst. C.E., M. Am. Soc. C. E. The branch, which for the present is located in Armament Buildings, Whitehall-place, will have the duty of considering projects for inventions relating to munitions for warfare on land, or matters appertaining thereto. The Comptroller and staff of the branch will be assisted in their work of examination, and, if thought necessary, in the investigation and development of any projects that may be considered worthy of being developed, by a panel of honorary scientific and other experts.

In order to prevent time fuses from turning whilst in transit, Krupps solder a wire across them sufficient to hold them in place, but yielding easily to the pressure of a key in the gunner's hand.

H. E. Shell Production in Ventilating Equipment Plant

Staff Article

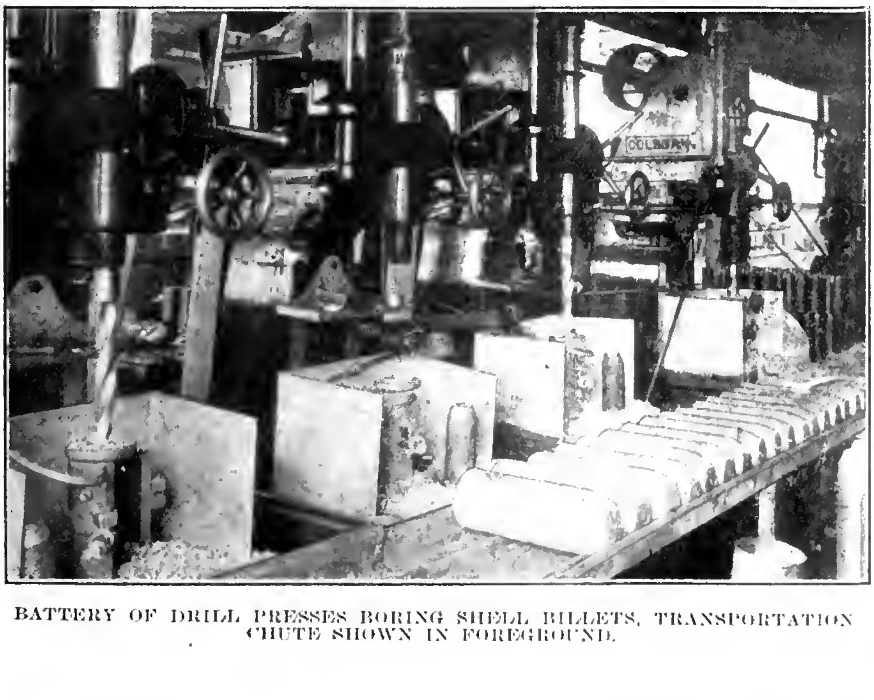
The plant which forms the subject of this article was among the first in Canada to undertake the production of 18-pdr. lyddite shells. Being accustomed, however, to manufacture machinery for special duty, little, if any difficulty was experienced in tackling successfully these war-time commodities. In addition to designing several ingenious fixtures and tools, a number of special machines have also been built and requisitioned for the work.

THE number of firms engaged in the manufacture of high explosive shells will no doubt increase, the demand for this type of shell having become quite insistent. Although some firms have reached the shipping stage and have overcome many of the difficulties with which they had to contend, there are others who have yet to go through the mill. The latter, however, will have the opportunity of benefiting from the experience gained by the pioneers and will no doubt take full advantage of it.

At the plant which is the subject of this article, 18-pdr. high-explosive shells are being made, the operations differing in many respects from those performed at plants which have already been described in **Canadian Machinery**. This feature will lend additional interest, especially in view of the fact that the results in most cases have been highly satisfactory. One feature worthy of notice is the method of centering the bar stock or billet at the base and using the centre instead of a chuck in practically all the more important operations, until the base recess is formed. This is done to obtain as concentric a shell as possible and at the same time increase production. The system of chutes between the machines in the earlier operations assists materially in speeding up production and reducing cost of handling.

The operations may be said to be divided into two sections. The first series are performed with practically only one exception on drilling machines which occupy a corner of the main shop on the ground floor. The second series, including rough turning the body, to the final operation, are all taken care of on the gallery over one bay of the main shop and extending the entire length. This arrangement was found to utilize the available space to the best advantage without interfering in any way with the ordinary or normal business of the concern. The layout of the plant is such that labor entailed in handling the billets and shells is reduced to a minimum with a consequent saving of time and money. The section of the plant used for making shells was laid out for this purpose, and it was thus possible to install each machine in its proper location to suit the sequence of operations.

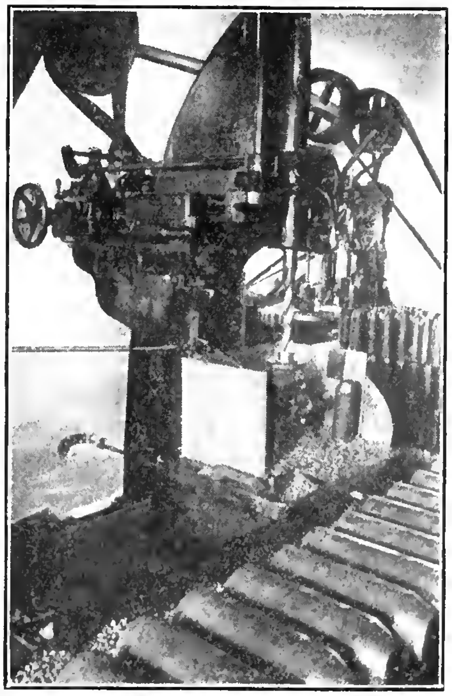
The drilling machines on the main floor already referred to are arranged as close together as is desirable, so that the shells can be conveyed from one machine to another by chutes in order to eliminate handling as much as possible. The billets are delivered to the shop and stored quite close to the machines, a supply thus being always at hand when required. In this section of the plant all the operations are performed from centering the bar stock to finishing inside, including threading the nose. A feature to be noted is the extensive use of drilling machines for the initial operations.



BATTERY OF DRILL PRESSES BORING SHELL BILLETS, TRANSPORTATION CHUTE SHOWN IN FOREGROUND.

Centering Billets.

The billets are first prepared for centering by grinding the corners and ends



BORING OUT SHELL BILLETS ON A "COLBURN" DRILL PRESS.

on a Canadian Buffalo Forge Co. grinder. They are then placed on a chute and passed along to a bench alongside which is a drill for centering the nose end of the billets. The drill was built by the Canadian Buffalo Forge Co., Berlin, Ont. The billet is held securely in a vise fastened to the drill table, and the centre drilled and countersunk in one end only. When this operation is completed, the billets are passed down another chute to the nosing machine. The nosing or rough turning the nose is done on three engine lathes. In this operation, one end of the billet is held in a collet chuck while the other end is being rough turned.

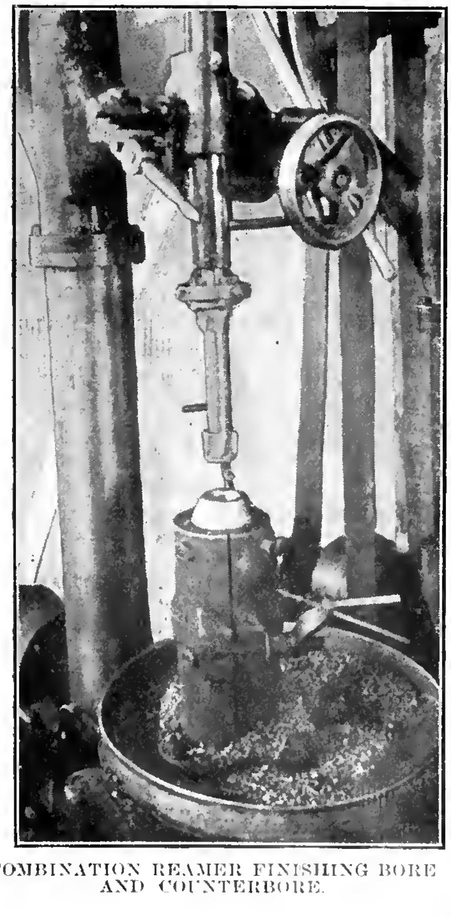
Rough Drilling Billet.

A battery of five heavy duty drilling machines is installed for the first drilling operation, which consists of a roughing cut only, the hole being finished later with a reamer. Four of these machines were built by Baker Bros., Toledo, O., and one by the Colburn Machine Co., Franklin, Pa. The "Baker" drills are all of the same type, and the "Colburn"

drill is very similar. Each machine is equipped with the same type of vise fastened to the table for holding the billet. The vise is a circular shaped device, one half being hinged and embracing a clamp. The stationary part of the vise has an extension bracket above with a hole in the centre through which the drill passes. The bracket supports a hardened steel collar used for keeping the drill central when beginning the cut.

The billets are laid out on a chute in front of the drilling machines, and when drilled are passed along to a bench behind for the next operation. Some interesting figures are available on the drilling operation. The four "Baker" drills operate at 130 r.p.m. with .013 feed, and the "Colburn" at 160 r.p.m., .019 feed. Whitman & Barnes and John Morrow & Son twist drills are used with the above machines. The installation of more drill presses is contemplated, these to be made by the Buffalo Forge Co., of Buffalo, N.Y., and designed especially for this work to operate at 190 rev., .020 feed. The hole in the billet is 1 13-16 in. diameter by 8¾ in. deep, and with the new drills this operation will take 2 minutes and 30 seconds.

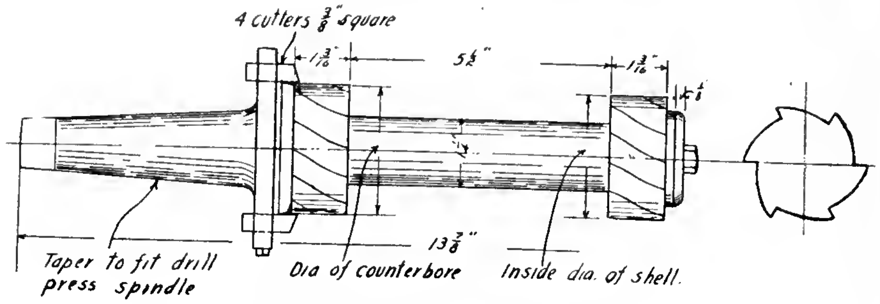
The bottom of the hole, after drilling, is of course the same shape as end of drill, and more metal must be removed in order to obtain the desired profile. For this reason the bottom of the hole is roughed out and reamed later. The roughing operation is done on a drill press supplied by the Aurora Tool Works, Aurora, Ind. The billet is held in a vise the same type as is used for the first drilling operation. The bottom of the hole is roughed to relieve the finishing tool at a later operation.



COMBINATION REAMER FINISHING BORE AND COUNTERBORE.

Inside Finishing Operations.

The next operation consists of finishing the inside body, reaming the counterbore, and roughing fuse plug seat. A 20-in. drill press built by the Canadian Buffalo Forge Co. is installed for this work. An interesting feature of the operation is the combination reamer designed by the Canadian Buffalo Forge Co. The reamer is about 13⅞ in. long over all and has a taper shank for fitting into the drill press spindle. At the end of the shank the reamer widens out, and has slots for four fly cutters. These cutters are ⅜ in. square and have a bevelled cutting face for forming the fuse plug seat. The cutters are held securely in position by a ring with a set-screw for each. Under the set of cutters is a reamer for finishing the counterbore in the nose preparatory to being threaded. At the other end of the spindle, the exact distance away, is another reaming cutter for finishing the bore of the shell. The cutters are secured to the spindle by dowel pins. In operation, the bottom cutter starts at the top of the hole, and travels down with power feed, followed by the cutter above. When both have nearly finished their work, the four small cutters above begin the form of the fuse plug seat. This combination makes a very accurate and efficient tool.



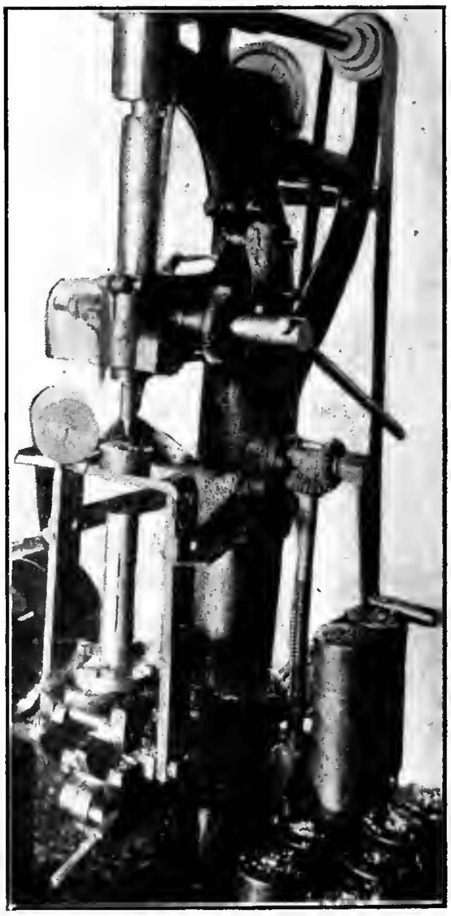
COMBINATION REAMER DETAIL.

Finishing Base Inside.

The bottom of the hole is finished on a 20-in. Canadian Buffalo Forge Co. drill press. The reamer has a long shank and is made with radius to suit the profile inside of the base. The shell is held in a hinged vise as in the previous operation.

In using unskilled labor it has been found advisable to do only one operation at each machine, and this principle has been followed as much as possible. Three drill presses, however, are equipped with a quick change "Wizard" chuck made by the McCroskey Reamer Co., and at the one setting of the shell the combination reamer is first inserted followed by the finishing reamer which can be inserted without stopping the drill.

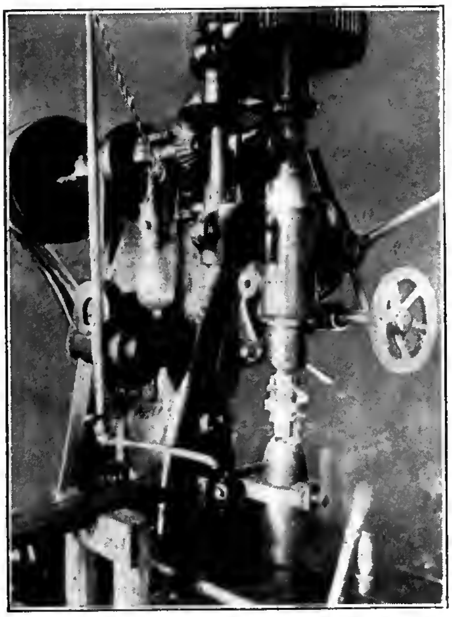
The shells are now moved to an adjoining machine to have the undercut or recess formed in the nose at the end of the counterbore. This undercut is necessary to give clearance for the threads. A 20-in. Canadian Buffalo Forge Co. drill press is installed for this operation. An expanding mandril fits into the drill press spindle. At the end of the mandril projecting out at the side is a small cutter the same shape as the undercut. The shell is held securely in a vise on the table, and the drill press spindle lowered until the cutter is in the correct position in the nose. A hand-wheel on the drill, when turned, causes the mandril to expand, and at the same time forces the cutter outwards, thus producing the undercut. This tool was made by the Toledo Twist Drill Co.



CENTERING OPERATION.

Centering Base.

It is necessary to centre the base end, as during several of the subsequent turning operations this centre is used. By always working from this same centre greater accuracy can be obtained and the shell will be concentric. This centering operation is done on a Canadian Buffalo Forge Co. drill press equipped with a special fixture for holding the shell. The base of the fixture is fastened to an arm extending from the drill press, and an expanding mandril is mounted on this base and works on a hinge so that the operator can swing it out to put the shell on. The mandril expands inside the shell and when moved into the vertical position holds the latter steady while being centered, the shell, of course, being nose end down. A bracket attached to the base of the fixture comes up over the shell and has a hole in the centre for a hardened steel guide to keep the drill and countersink central.



THREADING SHELL NOSE WITH COLLAPSIBLE TAP.

Threading and Tapping Nose.

The nose is threaded on a "Baker" drill, having a "Murchey" collapsible tap fitted in the spindle. A specially designed fixture for holding the shell is fastened to the table. This fixture has a floating clamp which holds the shell firm, but permits side movement; and is therefore self-centering. The centre in base of shell rests on a centre on drill table, while the shell is held in a clamp connected to a bracket at the side by means of a swinging hinge. A set-screw in the clamp keeps the shell from turning round while the nose is being tapped.

The sizing of the thread is done on a Canadian Buffalo Forge Co. 20-in. drill press with a standard sizing tap. The shell is held as before on a centre, with a floating clamp to keep it from turning. In the drill spindle, a Modern Tool Co. ball drive friction chuck is used, with a special bevelled facing milling cutter attached to the bottom of the chuck just above the tap. After the tap has been run down the full distance, the collar operating the ball drive is pushed up, which allows the milling cutter on the chuck to revolve, and there is sufficient clearance left to allow the cutter to be brought down to face the fuse hole seat on the end of the shell. This ensures a seat perfectly true with the thread. The drill is then reversed and the tap is backed off. One operator turns out 25 to 30 an hour.

After sizing, the shells are taken to a bench to have a centre plug screwed in the nose. They are then placed on a chute, at the end of which is a chain elevator, and are carried up to the floor above for the next series of operations. As the plugs are done with upstairs, they are sent back through a chute to be used again.

Rough Turning Shell Outside.

The lathes for performing this operation are situated at that end of the gallery above the drilling machines on the ground floor. They are, therefore, quite near the top of the elevator which brings the shells up to this floor. On leaving the elevator the shells travel down a chute within reach of the lathe operators. Four lathes, built by the Reed Prentice Co., Worcester, Mass, are installed for this operation, which consists of rough turning the body outside, roughing the copper band groove, and part of the base.

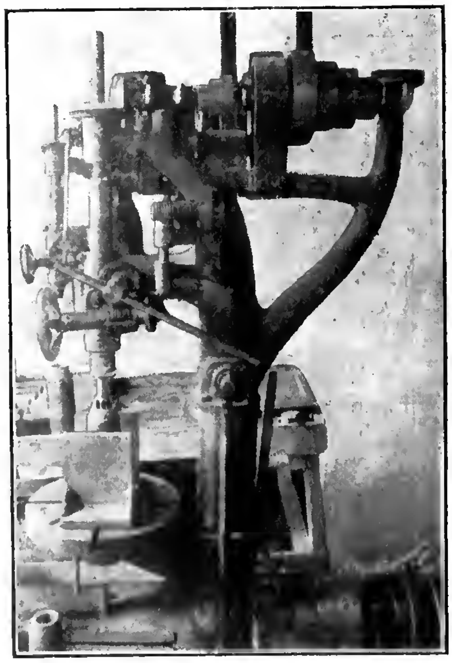
A centre plug has already been screwed into the nose of shell and fits the drive chuck. Both ends of shell are carried on the lathe centres. In front are two tool blocks mounted on separate cross slides, holding one and three tools respectively, the former for turning the nose, and the latter for the straight part of body. The tools are fed to the work by a cam device located under the cross slides, and attached to the lathe bed. A roller under the cross slide works in the cam. The left-hand tool rough turns the nose profile, the cam controlling the travel of cross slide. The three tools in the other tool block, rough turn the straight part of body.

While the front tools are working, the back arm is brought forward with its two tools and roughs the groove for the copper band, also squaring up the base of shell. Sufficient metal is left in the groove for the undercut and wave lines, which are finished at the next operation. The arm is clamped to a heavy bar at the back of the lathe, working in bearing brackets on headstock and tailstock. A projecting piece from the bottom of the arm has a roller which moves in a cam attached to a bracket on the lathe carriage at the back. The cam determines the feed of the back arm tools by moving the arm forward as the carriage travels. A stop in the bed in front controls the travel of carriage. After this operation the shells are arranged in racks.

Waving and Undercutting Copper Band Groove.

The next operation consists of forming the wave lines and undercut in the copper band groove. This is done on two "Reed-Prentice" 14-in. lathes, equipped with suitable tooling fixtures for the work. The shell has a centre plug in the nose, and is carried on the lathe centres, as in the preceding operation. Each lathe is equipped with a combination three-point cam and drive chuck, the latter having a square hole in centre to take the head of plug centre in shell nose, the same method being used in the preceding operation.

The waving tool box is in front and moves in longitudinal slides, the whole fixture being mounted on a cross slide. A bracket with a roller projects from the left-hand side of the tool holder. The roller at the end of the bracket is held up against the cam face by a spring on the opposite side of the tool holder. The cam oscillates the tool and gives the necessary motion to the waving tool. The tool has a square face with two vees for forming the wave lines. For feeding in the tool a cam is fastened on the lathe carriage under the cross slide, which has a roller underneath moving in the cam. As the carriage travels along, the cam forces in the cross slide and also the tool.



SIZING THREAD IN NOSE AND FINISHING FUSE-SEAT.

The undercutting tools are carried in two holders mounted on a fixture at the back of the lathe. They are hook-nosed,

right and left-hand, and are inverted. The holders are located close together and move in diagonal slides. The feed is taken care of by a cam fixture similar to the one which operates the waving tool. When the tools are feeding in, they are gradually forced apart, thus forming the undercut.

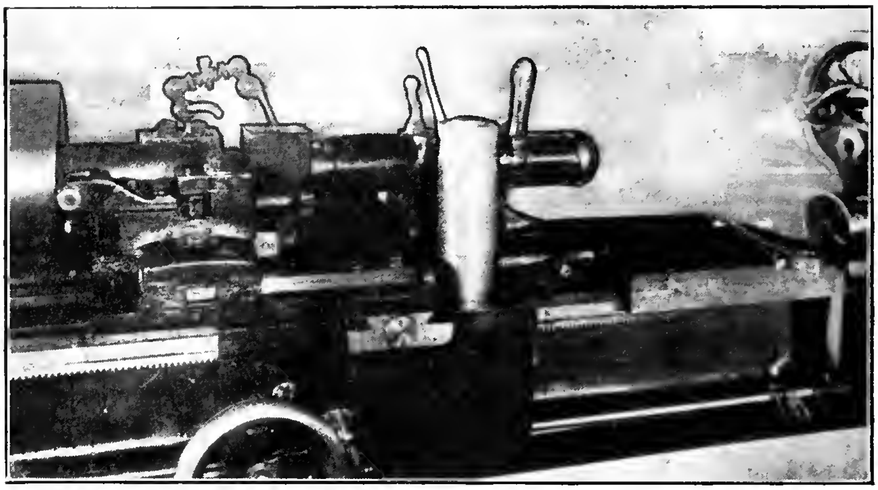
Finish Turning.

For the finish turning operation the same type of "Reed-Prentice" lathe is used as for rough turning. There are four of these lathes installed, and they are tooled up in a similar manner as the lathes used for the rough turning operation, with the exception of the back arm tools. In this case there are two arms, one having a tool for forming the corner at the base and the other for forming the fuse cap seat outside the nose. Three tools in one tool box in front finish turn the straight part of shell body, while a single tool, also in front, finishes the nose profile. The feeding-in cam is arranged in the same manner as on the roughing lathes.

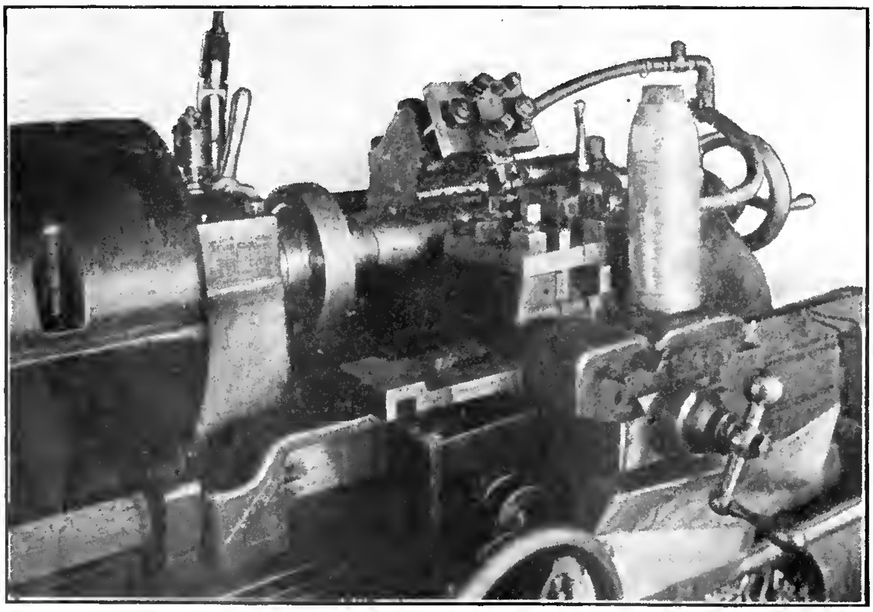
The back arms are operated, as in the roughing operation. The arm at the nose end holds a tool which forms the seat on the outside of the nose for the fuse cap, while the arm at the base end holds a tool for rounding the corner of base. These arms are brought forward when the front tools have nearly completed the travel. The shell has a plug centre in the nose, as in the two preceding operations, and is carried on the lathe centres, the same type of drive chuck being used as for the roughing operation. The lathe stops automatically when the tools have finished cutting. As the operation begins to move the carriage back, a catch on back of the carriage engages with a vertical rod connected to an attachment on the countershaft which throws over the belt. The time taken in this operation is 2 min. 15 sec. for one shell.

Driving Band Operations.

The shells now undergo the preliminary shop examination and Government inspection, when the body and wave lines are carefully examined. The wave lines are then nicked with a chisel and the shells taken over to the banding press. The latter was built by the Canadian Fairbanks-Morse Co., and is of standard design for shell work. The press is operated by hydraulic power from a belt-driven pump located close by. After the copper bands have been pressed on, the shells are taken over to a lathe for the bands to be turned.



WAVING AND UNDERCUTTING.



ROUGH TURNING BODY, NOSE PROFILE, DRIVING BAND GROOVE AND BASE.

The copper driving bands are turned on a "McDougall" engine lathe, equipped with a band-turning attachment built by Lymburner, Ltd., Montreal. The attachment is fixed to the lathe carriage. It has three tools—one in front for roughing, one under the work, also for roughing, and a tool at the back for finishing cut. The front tool and the one situated under the work are both operated by the screw under the front cross slide. The front tool feeds in towards the work, but the other feeds in a direction parallel to it. The underside tool roughs the back of the copper band, where the most metal has to be removed. The front tool then roughs the whole width of band.

The finishing tool is in a tool holder on the back of the attachment. The tool holder moves in vertical slides, and is operated by a lever. The tool passes down behind the work and is set so that it shaves off the required amount of metal while passing. The plug centre is still in the nose of shell, which is carried on the lathe centres. The lathe is equipped with a driving chuck to take end of nose plug.

Base Recess.

The base of shell up to this stage has retained the countersunk centre which was used during the various turning operations. This centre now disappears when the recess in base is formed. Before the actual work on the base recess begins, a flat 1 13-16 in. hole is drilled in the base to remove some of the metal, and so relieve the tools at the next operation. This relieving work is done on a 20-in. Canadian Buffalo Forge Co. drill press.

Four turret lathes, built by the Davis Machine Co., Rochester, N.Y., are installed for forming the base recess. The shell is held in a chuck, while on the turret are mounted the tools required for the operation. The turret is mounted on a cross slide, this feature being taken advantage of when boring out the recess and forming the undercut. The tool in the first turret face rough bores the recess. This tool is in the form of a cutter and is held in a boring bar. A stop with a roller at the end is fastened to the boring bar to regulate the depth

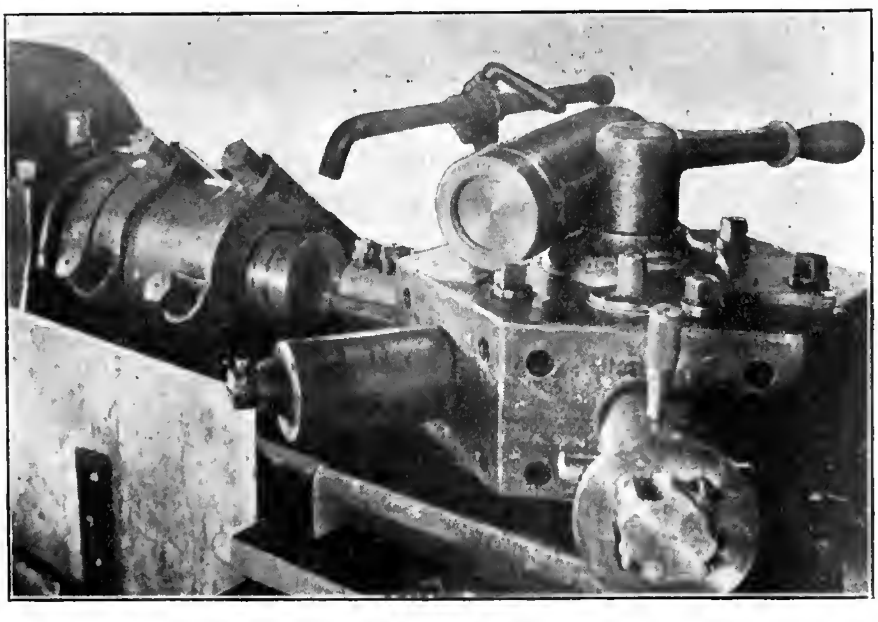
of the recess, the roller coming up against face of base, acting as a stop for cutter. The cross feed is taken care of by moving the turret. The second tool finishes the bottom of base and also the sides of recess for threading. This tool is of the same type as the roughing tool, and has a similar stop attached to the boring bar. The third turret face holds a boring bar, which has at the end a cutter for forming the undercut at the bottom of recess. In operation the tool is placed in position in the recess where the turret feeds across, thus forming the undercut. The fourth turret face holds a "Murchey" collapsible tap for threading the base recess.

Fixing Screw.

A number of minor operations now follow. The first is the sizing operation when the base is hand-tapped, the shells being moved along to a bench for this purpose. The ¼-in. fixing screw hole is then drilled and tapped. The hole is drilled on a Canadian Buffalo Forge Co. drill press, equipped with a specially-designed vise. The latter has a horizontal mandril, which is a sliding fit inside the shell, the mandril having a tightening device for holding base end of shell rigid. One end of the vise projects over nose of shell and carries a steel collar for guiding and locating the drill in the correct position. On a bench near the drill the hole is hand-tapped and sized.



FORMING BASE RECESS.

The shells are next cleaned and washed in a tank containing gasoline, afterwards undergoing another shop and Government inspection when the base recess is carefully examined.

Base Plate Operations.

The base plate operations consist of screwing the base plate into the recess, riveting the joint between base plate and base, and finishing the base. The base plate is a steel drop forging with a square head; the face has a slight camber and the periphery is threaded for about three-quarters of the width. The threads are covered with a cement composition before the base plate is screwed in, which is done by hand with a long wrench. When the base plate has bottomed in the recess the square head is twisted off.

The shells are now taken over to a power riveter to have the joint between the base plate and base closed up. The riveter was built by the Grant Mfg. & Machine Co., Bridgeport, Conn. The nose of the shell is placed on a cup-shaped block on the table while a bracket fixed to the frame above holds the shell steady. The hammer is operated by a friction pulley and is controlled by the operator by means of a foot lever. While the machine is working, the shell is turned round by hand one complete revolution.

The bases of the shells have now to be finished up, this being the last machining operation. A No. 3B "Milwaukee" miller is installed for this operation. A fixture is fastened to the table for holding 24 shells, two rows of 12 each, the shells being placed back to back with sufficient room in between for the cutter, and clamped to the fixture. The one cutter turns both rows of shells.

Marking.

After the base has been finished, the shells are taken along to a bench for the markings to be put on. The machine is fixed to the bench and was built by the Hamilton Gear & Machine Co., Toronto. This type of machine is installed in several shell plants.

Varnishing and Baking.

The shells while still on the bench have a brass ferrule screwed into the nose to prevent the varnish from coming in contact with the threads, the ferrule being taken out after the shells have been baked. The shells are filled with varnish from a tank, the tank used having been built by the Canadian Buffalo Forge Co. It consists of a double compartment, each side having a capacity of one barrel of varnish. The varnish is forced up from one compartment by compressed air. It flows up a pipe situated over the other compartment and the action is similar to a hot-

tle washer. The shell is simply slipped over the pipe, nose down, and, when lifted off, the inside is evenly coated with varnish free from air bubbles. The varnish runs down into the other compartment, and when the first compartment is empty and the other side full, the air pressure is diverted and the varnish is forced back in a similar manner.

It might be here stated that the object of the varnishing process is to protect the shell from the explosive, lyddite, which has a deleterious effect on steel. After the varnish has been poured out, the shells are placed nose down on a draining rack for a few hours preparatory to being baked.

A gas-heated oven built by the Brantford Oven & Rack Co., Brantford, Ont., is used for baking the shells. The oven is heated on the indirect system. On each side of the oven is a chamber with coils containing air which is drawn through ducts into the oven at the end by a Canadian Buffalo Forge Co. No. 2B exhauster. A gas burner is connected to each chamber and the hot gases flowing round the coils heat the air inside them. The air escapes through ducts located at the top of the oven. With this system, the gas fumes do not come in contact with the varnish in the shells, the hot air supplying the necessary heat. The shells remain in the oven eight hours, the temperature being 300 degs. Fah. The shells are arranged in racks before being placed in the oven.

Final Operations.

When the shells have cooled down, the ferrules are taken out and the shells are taken over to the Government inspector for final examination. The shells are carefully weighed, gauged and examined, and one from each series is selected for the firing test. The rest are then sent forward to the painting department where two coats of paint are applied, the priming coat being white and the second coat yellow ochre. A brass plug is then screwed into the nose, the threads being first covered with "luting." The shells next pass to the shipping room and are packed in boxes for shipment. The shell boxes used in this plant are made by the Hibner Furniture Co., Berlin, Ont., and the truck for moving the shell racks between the various operations on the gallery was supplied by the National Scale Co., Chicopee Falls, Mass.

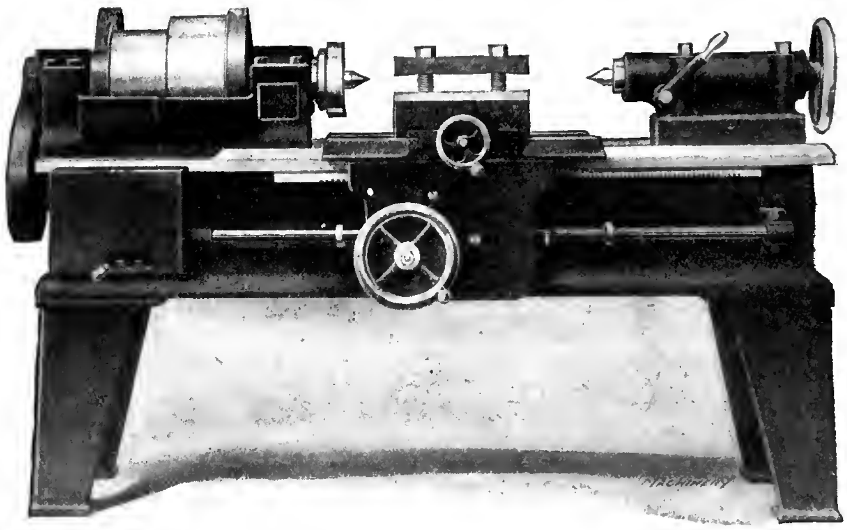
PROJECTILE MANUFACTURING LATHE.

THE opportunities afforded shell manufacture for the use of plain machines of limited capacity have been quickly recognized by machine tool builders. Among recent examples of these is the manufacturing lathe which has been put on the market by the Canadian Fairbanks-Morse Co.

It is designed to meet the demand for a plain heavy standard lathe, which can be easily handled by non-skilled labor, and in order to insure satisfactory service under severe and continuous duty, the provision of ample wearing surfaces and reliable lubrication, are distinctive features. The steel gearing is cut from the solid, and the headstock bearings are fitted with brass bushings and ring oilers. The lathe is regularly furnished with a solid spindle, having the nose bored for No. 5 "Morse" taper centre, but when desired it can be furnished with a hole 3⅛ inches diameter, and deep enough to hold a 3-inch shell.

The carriage has power longitudinal feed only. Automatic stops control this obtained by means of a shifting lever in the gear box. The feed is positively driven by gears from the spindle, all gears suitably covered. The tool box is of the European type, of ample proportions, and has hand cross-feed only. Two speeds only are furnished by the 6 in. wide cone steps, which are of 11 and 14 inches diameter respectively. The use of a two-speed countershaft provides eight speeds, the countershaft friction driving pulleys being both 16 x 6 inches.

The bed is 7 feet long and allows 21 inches between centres. A maximum swing of 16 inches diameter is available over the bed, and 10 inches over the carriage. The liberal proportions of spindle bearings—5 x 7⅜ inches front and 4½ feed in either direction; three changes of feed—⅛, 1-16 and 1-32-inch, being x 5⅜ inches rear—insure ample rigidity under severe service. When desired, this lathe can be furnished with various attachments for different operations.



16-INCH SWING, MANUFACTURING LATHE.

ENGINEERING IN GERMANY

THE Copenhagen correspondent of "Electrical Engineering" writes: "It is wrong to say that the electrical industry in Germany is disorganized. In my opinion it has never been so organized as at present, but the whole organization has been altered to meet the war requirements. The Government has taken over practically the whole supply of brass and copper and other metals useful for war purposes. A vast number of factories are working day and night on Government orders, and, as the German Government pays tremendous prices, the firms having this sort of work do not care for any other. However, in the electrical industry there are a large number of small firms, especially down in the Thuringen neighborhood. Most of these firms have no Government work, but they cannot supply the usual accessories because all their stocks of metals have been taken from them. Therefore, they have now to make lamp-holders, lamp-sockets, switches, and, in fact, all accessories, of brass-covered iron. With their usual technical thoroughness and cleverness they have succeeded in producing an article of first-class quality. The finished article looks exactly like brass, can be polished like brass, and, I believe, withstands moisture and other rough treatment. For a long time the Germans have been using insulated iron wires instead of copper wires."

Cheap Ammonia.—Ammonia, as ammonium sulphate, is produced cheaply as a by-product in the manufacture of coke in by-product ovens.

Steel and Shrapnel Bullets.—The least thickness of hardened steel that will keep out modern shrapnel bullets at fairly close range is ⅛ in. These bullets run forty-one to the lb.

Casting Steel Ingots for Production of 4.5 H.E. Shells

Staff Article

With a view to securing an increased output of 4.5 high explosive shells, cast steel billets are now being produced in our steel foundries through the medium of ingot moulds. Although in the earlier stages of the process considerable trouble and difficulty were met with, these have now been overcome and, in the particular plant under review, an output of over 4,000 shell blanks each 24-hour day is being achieved and continuously maintained.

WONDERFUL developments have been, and are still taking place in the iron and steel industry throughout the Dominion of Canada. While the manufacture of iron castings has for the most part in the past occupied the attention of foundrymen, that of steel castings is of comparatively recent date.

Prominent among Canadian concerns engaged in this production is to be noted the Canadian Steel Foundries, Ltd., of Montreal, etc. This company which was organized in 1910, have a large plant located at Longue Pointe on the outskirts of Montreal, for the express purpose of manufacturing steel castings of almost any size or shape, the meantime capacity being something over 3,000 tons per month.

The output had however been more or less restricted for some time owing to the generally prevailing industrial depression, but, on the advent of shell making, so great was the impetus imparted through the demand for shell steel billets, the plant is now running night and day to meet the new situation and at the same time do justice to its regular lines, among the latter of which may be mentioned locomotive frames, wheel centers, engine castings, high carbon rolls, dredge buckets, etc. A specialty is made of all kinds of steam and electric railway track work, such as frogs, switches, diamonds, intersections, etc. Vanadium steel is prominent in all products where great strength is desired.

The plant is located about a quarter of a mile from the St. Lawrence river and about a mile east of Montreal city boundary. The buildings are of structural steel and brick, erected on concrete foundations. A detail description of the constructional features was given in our October, 1912, issue of Canadian Foundryman.

The Steel Foundry.

This building is 436 feet long and has a width of 264 feet. It consists of five sections there being an aisle across one end of the shop.

The open hearth charging stock is brought into the shop and taken to the furnaces by a Morgan 5-ton, four motor high type charging machine. The two 25-ton acid furnaces, using oil fuel, are of the most modern design and construction, and should the oil fuel fail or be cut off a gas producer is arranged as a standby.

The first aisle on the east side is equipped with a 20-ton Dominion Bridge Co. crane and also a 30-ton "Morgan" crane, while jib cranes fitted with air hoists are on each side of every aisle for handling the flasks and moulds, all of the flasks being of heavy cast steel and in a variety of shapes and sizes.

Mould Drying and Pouring.

After the moulds are made they are taken on trucks to a battery of drying ovens equipped with "Kinnear" rolling doors. Following the drying, the moulds are removed to the casting floor and placed in readiness for pouring. Two 35-ton and three 24-ton steel ladles built by the John McDougall Caledonian Iron Works, are used in transferring the molten steel from the furnaces to the waiting moulds. One 20-ton Dominion Bridge Co., and two "Morgan" cranes of 30 and 40-ton capacity transport the above mentioned ladles.

Fettling Shop.

When the castings are sufficiently set they are shaken out and removed to the fettling shop which comprises the aisle at the end of the foundry. Here a variety of equipment prepares the casting for machining by removing all gates, fins, etc. This aisle is served by a 15-ton Dominion Bridge Co. and a 30-ton "Morgan" crane as well as by a "Whiting" electric travelling wall jib crane. A general view of this floor is shown in Fig. 1.

Billets for Shell Production.

Owing to the great difficulty on the part of many plants in obtaining rolled steel billets for the production of shrapnel and high explosive shells required

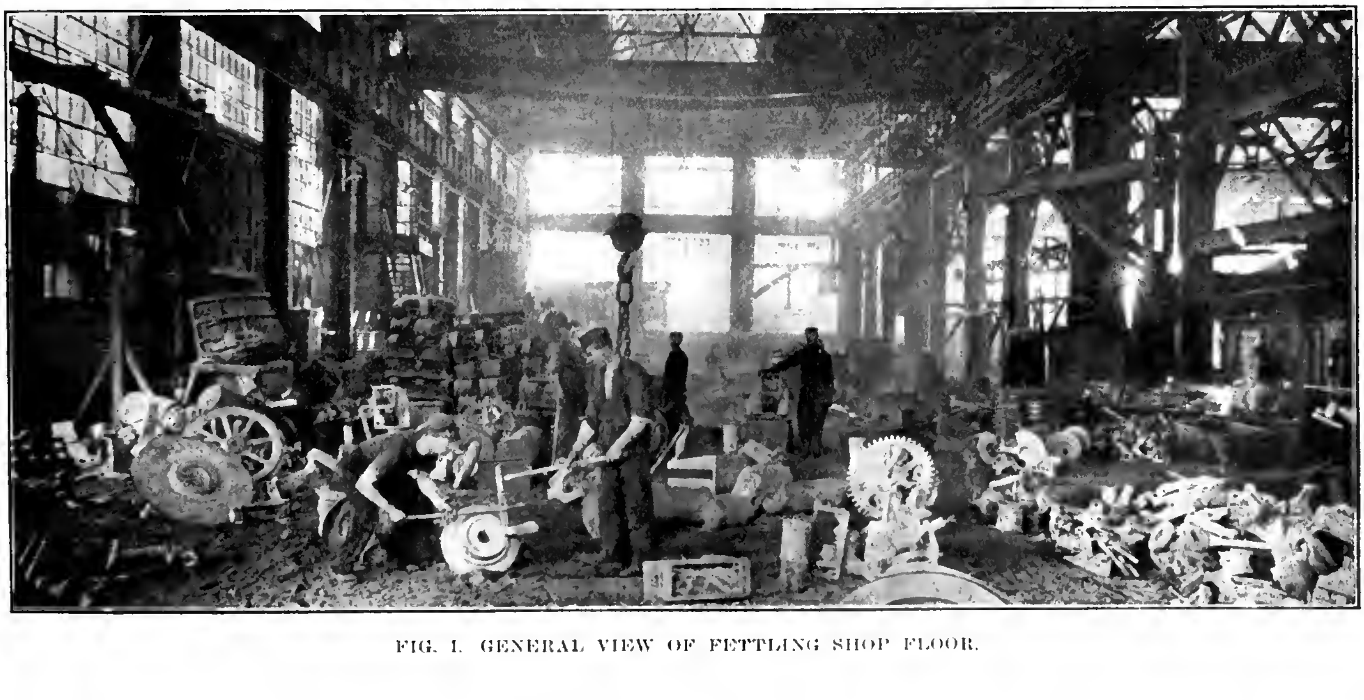


FIG. 1. GENERAL VIEW OF FETTLING SHOP FLOOR.

for the various European nations, our steel foundries have been scheming and experimenting with a varying amount of success so as to produce a grade of steel casting that would meet the requirements.

While the art of making steel in metal moulds dates back to the days when crucibles were first used in making small tool steel ingots, the more general adoption of metal moulds dates back only a few years.

On first thoughts it did not appear to be practicable to produce the desired grade of steel required for shells by the ingot moulding process, especially as the rough shell had to be forged from the cast ingot. However, after much time spent in experimenting, a stage has been reached at which almost every requirement is fulfilled. It was believed that the use of metal moulds would chill the steel and cause it to be unserviceable for shell making, but with moulds of proper proportions, results otherwise have been achieved. No annealing has been found necessary after the ingots are shaken from the moulds.

Government Specifications.

Government specification requirements for 4.5 shell steel call for the same standard of product as in the case of 15 and 18 pounder shrapnel shells. The steel must have a tensile strength of between 35 and 49 long tons, an elongation of about 20%, a percentage of carbon between 0.45 and 0.55; the quantity of nickel must not exceed 0.50, manganese to be between 0.40 and 1.00, and phosphorus not over 0.05 per cent.

A mixture that gives close results is composed of about 20 per cent. Chautauqua or a similar low phosphorus pig iron, 40 per cent. open hearth scrap steel and the balance of heavy melting steel scrap.

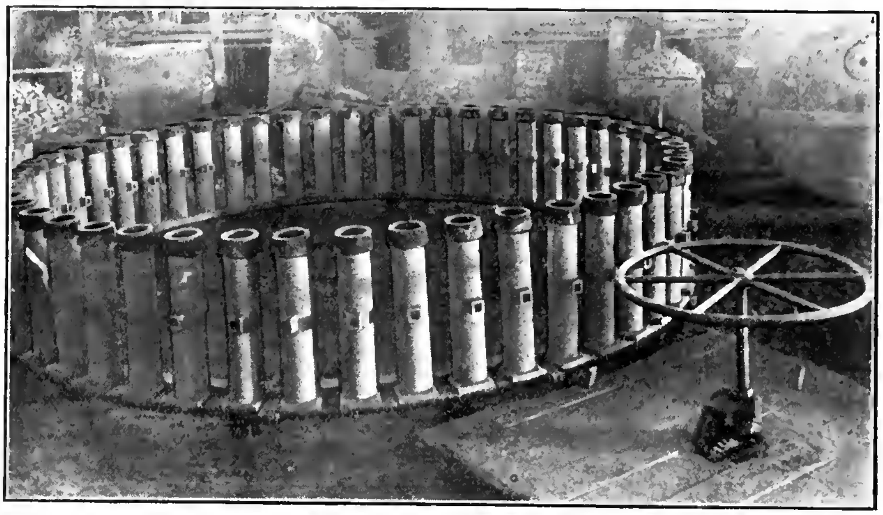

FIG. 4. BATTERY OF INGOT MOULDS READY TO BE POURED.

Melting the Mixture.

The steel is produced in two 30-ton furnaces by the open hearth process. They are fired with fuel oil at a pressure of 80 lbs. per sq. in. mixed with air at 100 lbs. per sq. in. The quantity of oil used is comparatively low, being about 3.3 or 3.4 gallons per ton of steel melted. One charge is melted in about 5 hours. The entire charge of about 25 tons is taken from the furnace by running it into a 40-ton bottom-pouring ladle shown in Fig. 2. This ladle, made by the John McDougall Caledonian Iron Works is built of heavy boiler plate lined throughout with fire-brick. The molten metal is poured from the ladle through an opening in the bottom which is stopped by a plug controlled by a series of rods and levers operated manually at some distance off. The stop plug which controls the flow of the metal from the ladle is made of graphite, the part entering the opening being conical in shape with the end somewhat rounded. This graphite plug is screwed on to a rod which extends down through the metal from the top of the ladle.

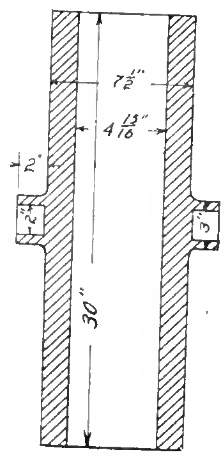

FIG. 3. INGOT MOLD.

To protect this rod from the action of the molten metal, it is covered with a series of fire-brick discs throughout its length. Owing to erosion the graphite plugs will only stand about 300 openings after which they are replaced by new ones.

FIG. 2. FILLING BOTTOM POURING LADLE AT OPEN-HEARTH FURNACE.

Shell Ingot Moulds.

A rough sketch of the moulds used for making the shell ingots is shown Fig. 3. At first the moulds were made somewhat shorter but as it was desired to get two blanks from each ingot, it became necessary to increase the length in order to get sufficient sound steel at the bottom. The trunnions are placed a little above the centre to facilitate handling with the crane, while both ends are faced off to obtain a good level surface. The caps for these moulds are made of facing sand in a core box and oven-baked. The general construction is shown in Fig. 6, the bottom end being narrowed down to facilitate removal.

Preparing the Moulds.

When the ingots were being first produced, it was the custom to stand them

in hit-and-miss fashion about the floor. This method was found unsatisfactory, however, as the crane operator had considerable difficulty in placing the opening of the ladle in the desired position. To overcome this trouble and also to facilitate the operations generally, the method shown in Fig. 4 was designed and is giving excellent results.

A rotary table with rack underneath is constructed to run on a track, and is operated by bevel gears and shafts leading to the large hand wheel shown in Figs. 4 and 5. These rotary tables are 16 ft. 8 ins. inside and 18 ft. 4 ins. outside diameter, and have flat surfaces upon which the moulds rest; the latter being held in position entirely by their own weight. At present there are four of these tables in use, each having a capacity of 50 moulds. There is also under consideration a new design which will involve a table to accommodate 2 concentric rows of 50 moulds each. This will do away with the handling of the crane after the first mould has been located.

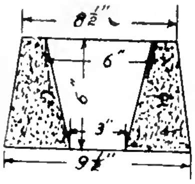

FIG. 6. INGOT MOLD CAP.

Pouring the Moulds.

After the charge has been taken from the furnace, the 40-ton ladle is picked up by the crane and taken to a position directly over the revolving table. When the proper location is found and the first mould poured, directions are given to the men at the controlling wheel and the table is revolved to the next mould. The man standing close to the ladle directs the movements of the crane operator and also the men at the wheel, his eyes being protected from the glare and heat by heavy blue glass goggles. The entire heat of around 25 tons is run off in about one hour.

FIG. 5. POURING A BATTERY OF INGOT MOLDS.

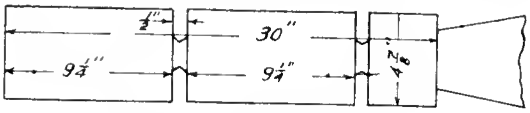

FIG. 8. SYSTEM OF CUTTING OFF BILLETS.

The magnitude of these operations can be best realized when it is known that an average of seven heats of 25 tons each, which is about 4,000 shell blanks, are run off every 24 hours.

Removing the Ingots.

When the ingots have properly set, although still quite hot, they are removed from the mould so that the latter can be prepared for the next pour. The ingots are raised by means of the crane and in most cases they drop out without any trouble, as the shrinkage, which

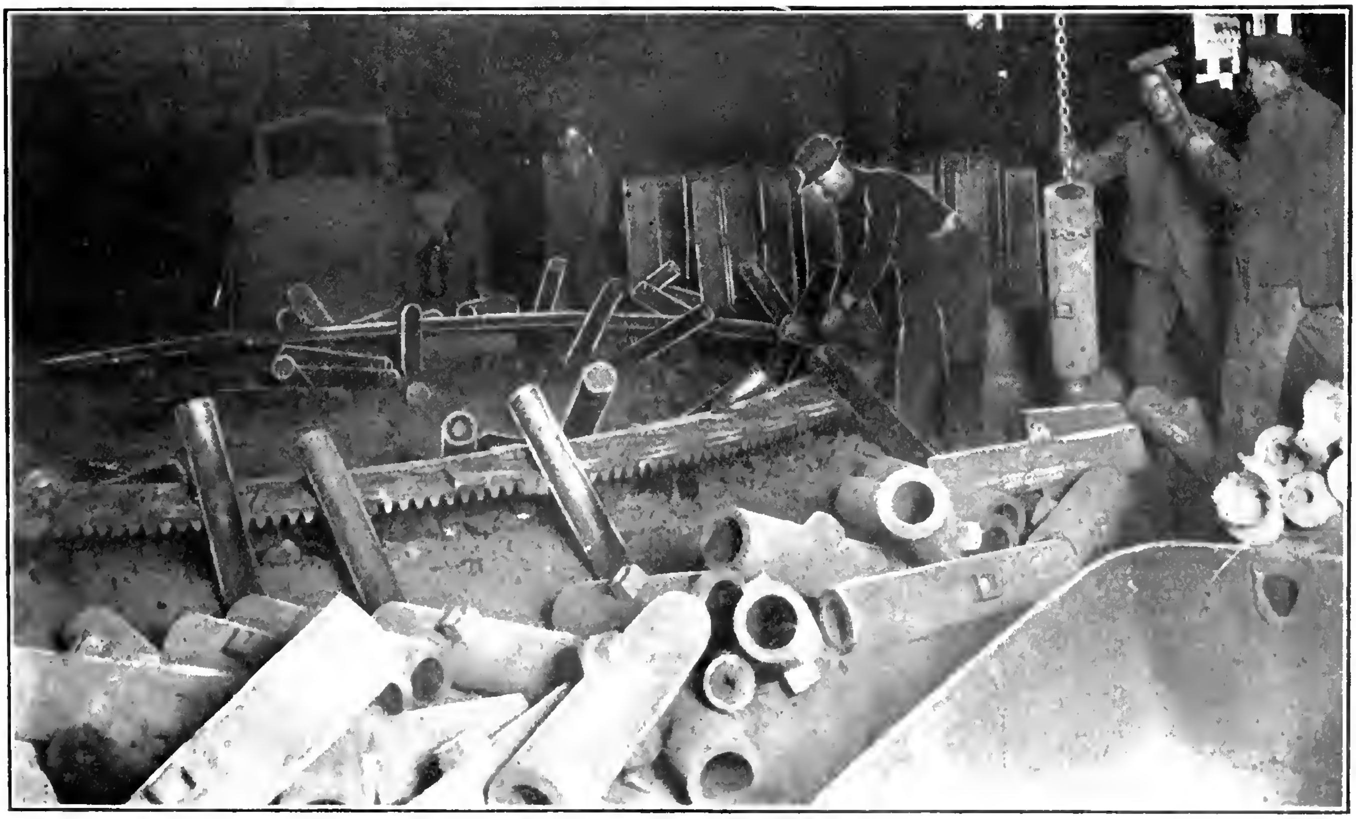

FIG. 7. SHAKING OUT THE INGOTS, SEVERAL OF WHICH MAY BE SEEN AGAINST THE TABLE.

is about 3-32 of an inch in the diameter of 5 inches, is usually sufficient to thoroughly free the ingot from the mould. Sometimes however, it is necessary to hit the ingot a blow with a sledge. If they do not come out with the sledge treatment they are taken to a "Bertram" horizontal hydraulic press and forced out.

Occasionally an ingot seizes in the mould, and when this happens the contraction will cause the metal of the mould to crack in one or more places; however, the loss in this respect is very slight, being less than 3 per cent. The walls are left thick enough to withstand the action of the heated metal, because, if too thin, the molten steel would tend to heat the mould so rapidly that the two surfaces would incline to weld together. After the ingots are shaken out, they are inspected for defects, such as fractures "piping," etc. The life of the average mould is about 200 heats. A view of the shaking out process is shown in Fig. 7.

Cutting Off the Billets.

After the ingots have passed the preliminary inspection they are cut into billets on several axle lathes; the length being 9¼ inches, and the width of cut being from ⅜ to ½ inch wide. The cutting off tools are of "Firth" high speed steel. Six lathes are employed in this operation, two of them being "Bridgeford" products and another two of "Bertram" make. The depth of cut is approximately 2 ins., the tools being fed in by hand. The average time for four cuts is twelve minutes, and about 200 billets are obtained in 10 hours. Each ingot weighs about 156 lbs. and is handled by means of a jib crane and air hoist. The Government inspection calls for a portion equal to about 1-6 of the cross sectional area to be left in the centre, so that, when broken apart it can be examined for fracture. A sketch of one of these ingots as it comes from the lathe is shown in Fig. 8.

FIG. 9. RECORD SHEET COVERING CHEMICAL TEST.

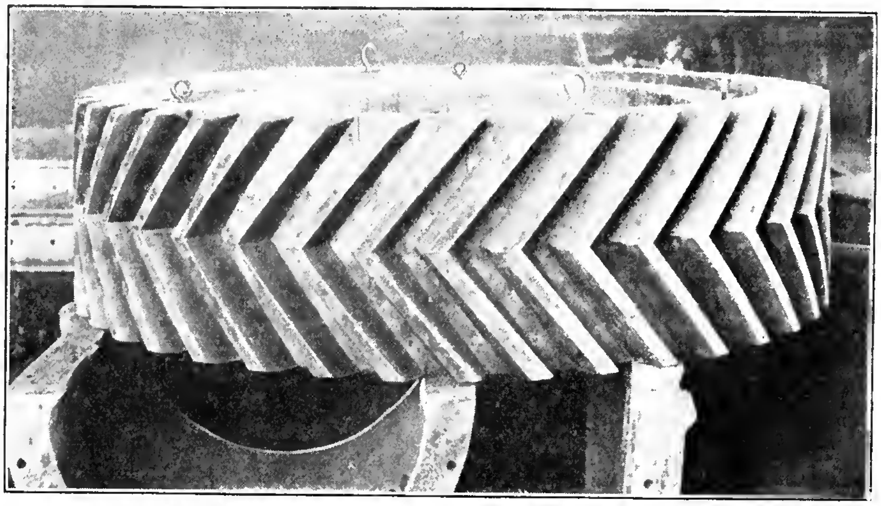

FIG. 10. PATTERN OF LARGE HERRING-BONE GEAR.

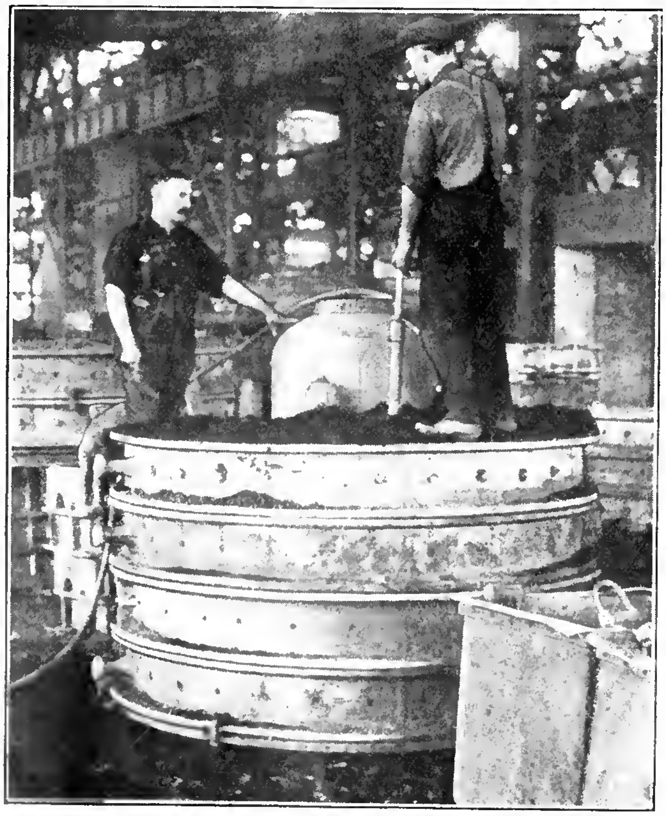

FIG. 11. PREPARING MOLD FOR LARGE STEEL HYDRAULIC CYLINDER.

Inspection.

The billets are broken apart by laying across a 3 x 4 block and striking with a sledge. The crop end is returned to the furnace for remelting and the billets again inspected for defects. If rejected at this stage they are stamped with the letter R. The buttons are removed by planing or shaping, or, if very shallow, by grinding. Two sample ingots are taken from each heat for analysis. Drillings are also taken for tests of carbon, sulphur, phosphorus and manganese. The carbon test is derived by combustion, as the color test gives only an approximation. Chemical and physical tests are made of each heat by the works chemist, also by the Government chemist, and records of these are preserved. One of these record slips is shown in Fig. 9.

General.

While this plant is busy at present supplying machine shops with steel billets for the manufacture of 4.5 high explosive shells a general line of heavy steel castings is also being turned out. An idea of these latter may be got from Fig. 10, in which is shown the pattern of a large herringbone gear of about 8 feet in diameter, and in Fig. 11, the mould for a large hydraulic press cylinder in course of preparation.

The first contingent of volunteer munitions workers left Johannesburg, South Africa, on August 5, for England.

SHRAPNEL SHELL PRODUCTION IN A SHIPBUILDING AND MARINE ENGINEERING PLANT

Staff Article

The sudden call from the manufacture of articles of a peaceful commerce to that of supplying the gods of war with provender of a prodigious amount and such as we never dreamed of producing, has been met by the administrations of our iron and steel industries in a manner that demands our whole-hearted admiration for their enterprise and resourcefulness. This particular plant is now making arrangements to manufacture 4.5 high explosive shells.

FROM building ships to making shrapnel shells represents somewhat a switching between extremes, and naturally called for changes in and additions to equipment. At the plant under review, however, little difficulty was experienced in finding room for a shell department which would not interfere with the ordinary work. A portion of the ground floor of the machine shop was taken over for the purpose and equipped with the necessary machinery. The floor or gallery above was also utilized for the making of shells. The heavier tools are installed on the ground floor and the operations up to and including the finish turning are done there.

On the gallery above, a banding press and band-turning lathe, a socket finishing lathe and a milling machine represent the machines installed, the greater part of the space being devoted to the assembling, painting and other hand operations, and to the housing of the inspection department. The entire plant is laid out so that the shells start at one end and are handled progressively until finished. "Chapman" elevating trucks distribute the shells between the various operations. Cutting compound supplied by the Cataract Refining Co., Toronto, Ont., is used exclusively on the various cutting tools. The heat treating department is located in a separate building outside of and adjoining the machine shop. This arrangement helps considerably in keeping the latter cool and free from fumes.

Although not among the first firms to undertake the manufacture of shrapnel shell, good progress has been made and little time has been lost in getting to the shipping stage. A number of "short cuts" and time-saving appliances have been introduced to increase production. The shops are equipped with electric motors using hydro power, and a spur from the G. T. R. runs through the yard to the machine shop, bringing the forgings right up to the door. The forgings are stored just outside, and the cutting-off machines are located at that end of the shop within a short distance of the pile.

Cutting Off to Length.

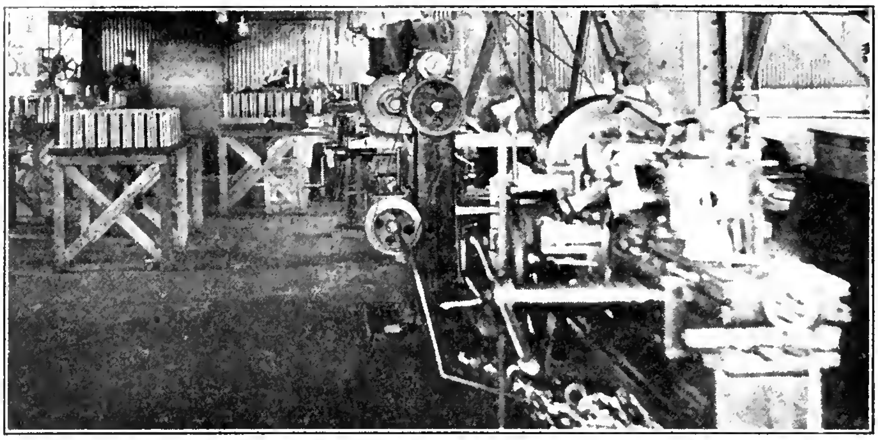
The machining of the shell forging begins at the base, which is cut to length on a cutting-off machine supplied by John H. Hall & Son, Brantford, Ont. The advantage obtained by machining the base first before cutting off the open end is that it gives a square face to work to for the later operation, and also has the advantage of keeping the length of forging in a definite relation to the thickness of base. The machine is equipped with a universal chuck for holding the shell, and a bar stop inside the headstock spindle locates the forging in the correct position. The stop, of course, comes up against the base of the shell inside. On the bed of the machine is a saddle, on which are mounted two cross slides, with holder on each, front and back. The cross slides are operated by a spindle threaded right and left-hand respectively, so that the tools always feed in when cutting. The back tool is set slightly ahead of the front,

PART OF MAIN FLOOR OF SHELL SHOP SHOWING MACHINES' LOCATION FOR FIRST SERIES OF OPERATIONS.

thus allowing a heavy cut being taken off. The hand screw at the right side traverses the saddle longitudinally.

Cutting Off Open End.

The open end of shell is cut off on the same type of machine as described above, the only difference being a shorter bar stop in the headstock and different cutting tools. The shell forging is placed in the chuck, the base end being up against the bar stop; the chuck is then tightened up. Both tool holders are used as in the previous operation, but in this case the parting tools are set in line with one another, the back tool being inverted to bring the cutting edge central. The shell forging is now the approximate length and ready for the body rough turned.

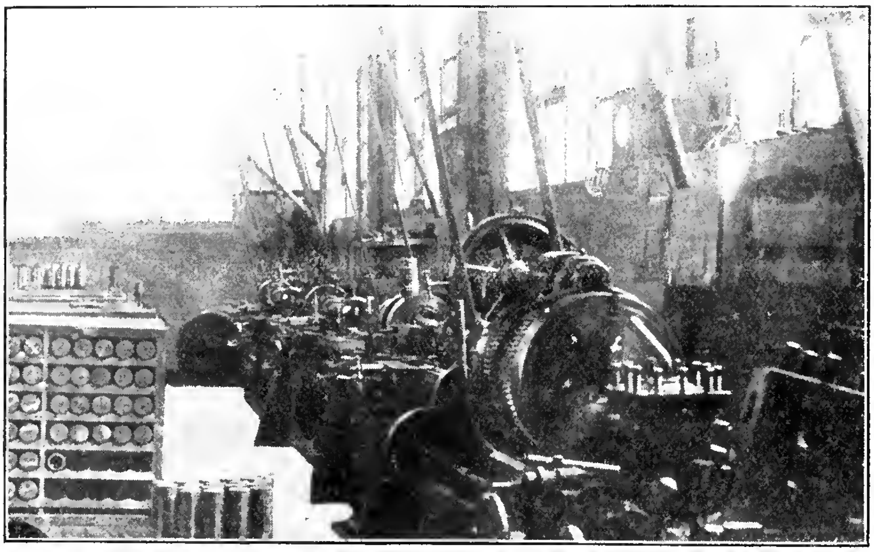


SHELL SHOP GALLERY SHOWING ASSEMBLY.

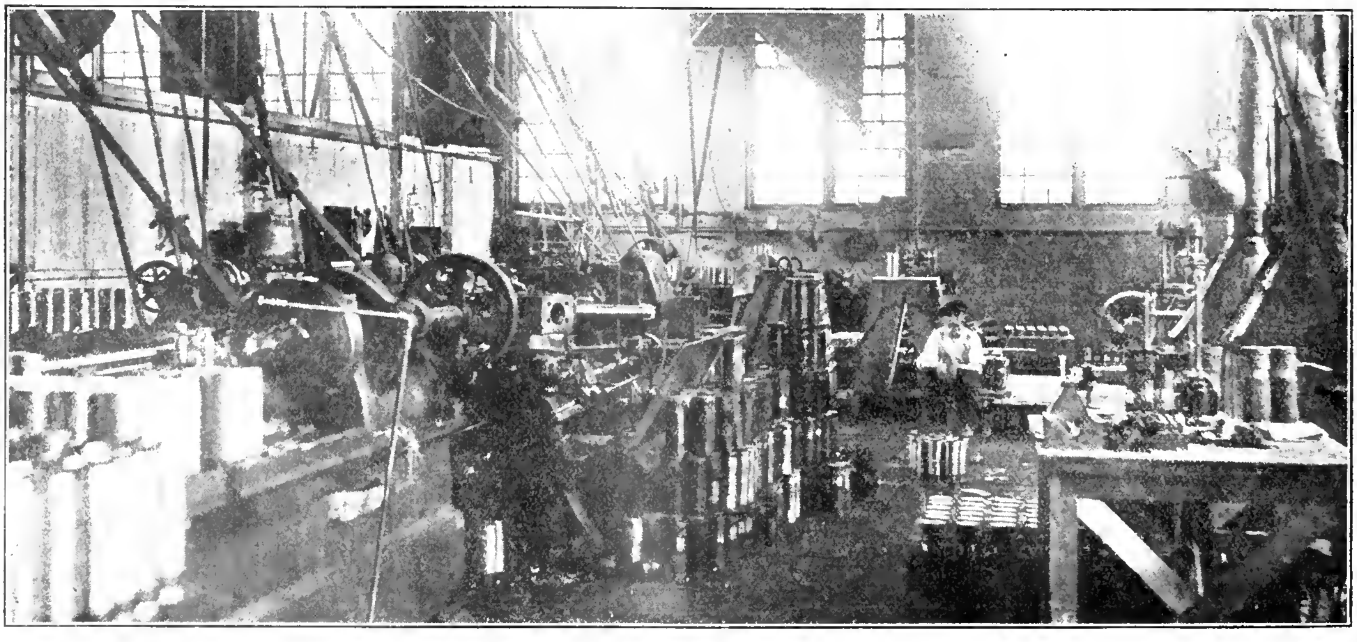
Rough Turning Body and Facing Up Base.

At the next operation the body is rough turned, the base faced up and corner rounded off, and the body up to the driving band groove finished. Two "Bertram" engine lathes are installed for this work, each being tooled up in identically the same manner. In order to have the outside of forging concentric with the inside, the shell is held on a mandril with a draw-back mechanism. The open end is also gripped in a universal chuck, which rotates the shell by means of a ring attached to the latter by three set screws.

On the cross slide is mounted a specially-designed fixture for holding the three tools for performing the operation. Two of the tools are set in line with the side of the shell and the third behind the base. The first tool held in an ordinary tool-holder rough turns the body of the shell for a distance of about 7 5/16 in. from the base, leaving the nose bevel to be machined later. The second tool, also at the side, is used for finishing the shell from the base to the driving band groove. This tool is held in a special holder, and can be moved back from the work at the end of the cut. The third tool is a broad cutter so formed that, while the base is being finished, the corner is rounded off at the same time. This tool is, as has already been stated, lo-



CORNER OF SHELL SHOP, SHOWING "WAVING" AND FINISHING LATHES.



SHELL SHOP, MAIN FLOOR, BEFORE HEAT TREATING DEPARTMENT WAS MOVED TO A SEPARATE BUILDING.

cated behind the base of shell, and is shown at the right in the illustration.

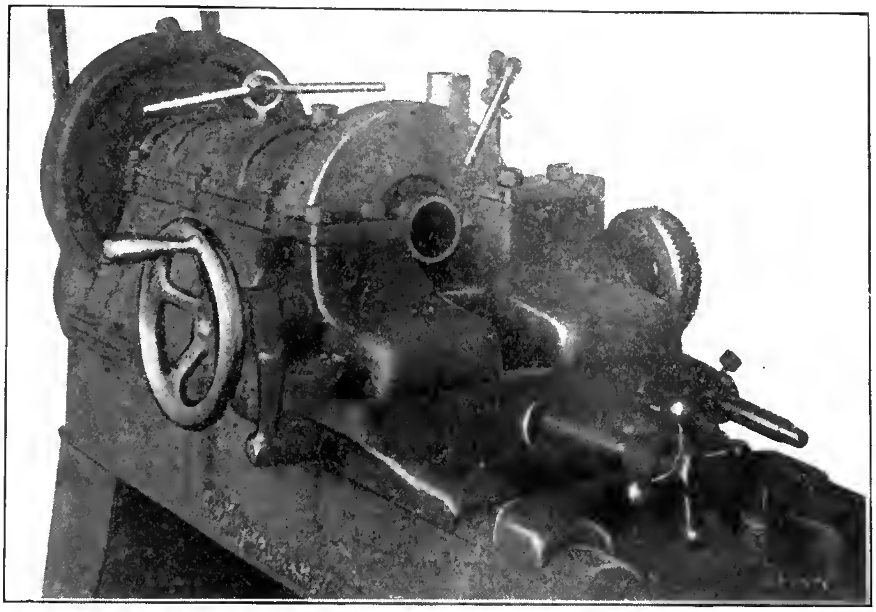
Machining Powder Pocket, Diaphragm Seat and Outside Nose Bevel.

This, the first operation on the inside of the shell, is performed on a "Warner & Swasey" turret lathe, the turret holding the tools for the inside work, while a tool holder on the cross slide contains three tools for machining the outside of nose. The shell is held in a universal chuck, which has a bush inside conforming to the shape of the shell base, and is used for locating the shell in the required position for machining. In this case it is immaterial whether the outside or inside work is done first. The usual method of procedure, and done in order to save time, is to reverse the order for each shell—that is to say, if the nose bevel was formed last on one shell it would be the first operation on the next, with the same rotation for the powder pocket, etc. By this means, one setting of the tools does for two shells. As an illustration the inside boring will be described first.

On the first turret face is a boring bar with a cutter for roughing out the powder pocket and diaphragm seat. The second boring bar has a cutter of similar shape, conforming to the profile of inside base of shell, for finishing the powder pocket and diaphragm seat. The inside work at the base is now finished and the turret is moved back out of the way to permit of the nose bevel being formed. The tool holder on the cross slide contains three tools for rough turning the nose outside and cutting to length. It should be stated that the nose at this stage must be of a certain shape or bevel so that after the closing in operation it conforms to the required profile. The first tool cuts the shell to length, not, of course, the finished length, as this is done at a later operation. The second tool is a taper cutter for forming the bevelled part of nose behind the straight section at the front. This straight part is rough turned by the third tool. This operation is now completed, and when starting on the next shell, the nose bevel is machined first, followed by the powder pocket, etc.

Waving, Grooving and Undercutting.

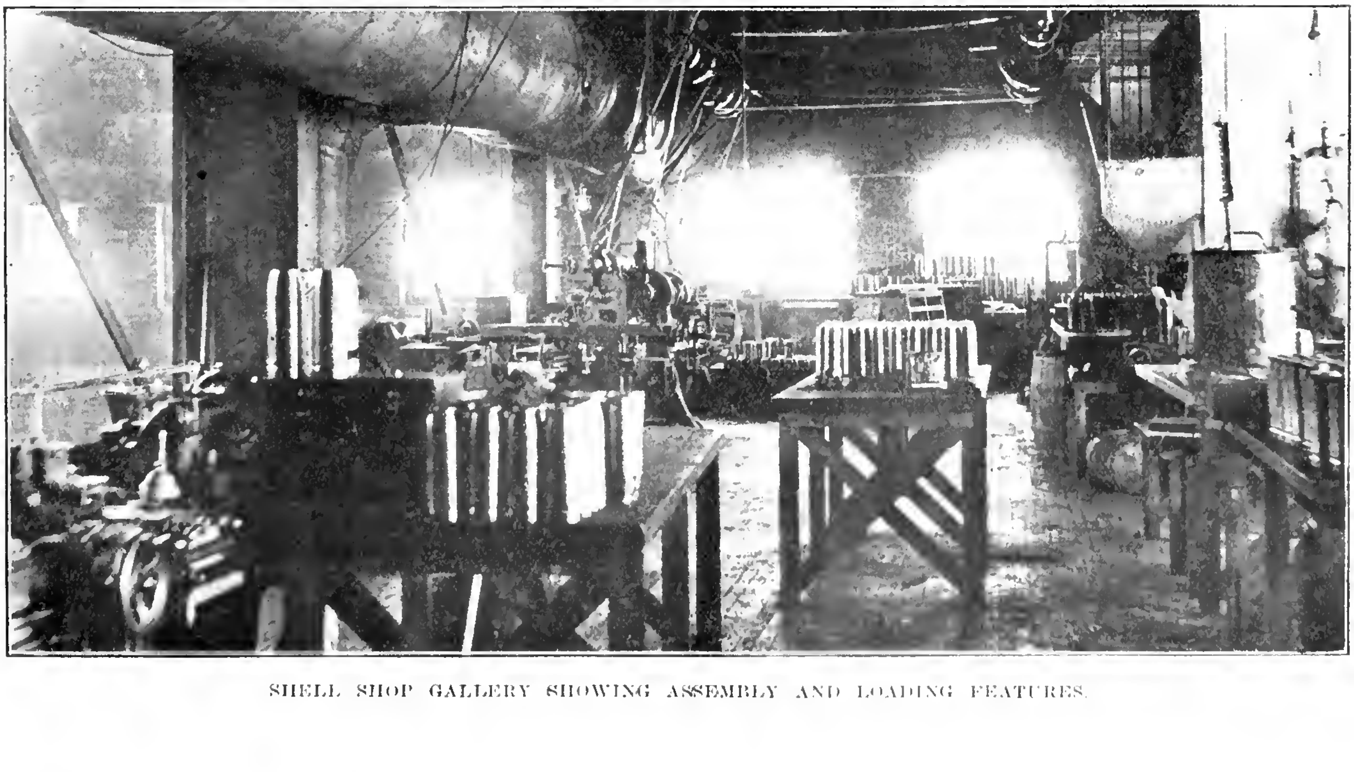
For this operation two engine lathes are installed, built respectively by the Canada Machine Corporation, Galt, Ont., and Flather & Co., Nashua, N.H. Both machines are equipped with a "Bertram" waving and undercutting attachment with a three-point cam, also a bar stop in the centre of chuck for fixing the position of the shell. The nose end of the shell is, of course, held in the chuck,



TRIMMING OPEN ENDS AND BASES OF SHELLS.

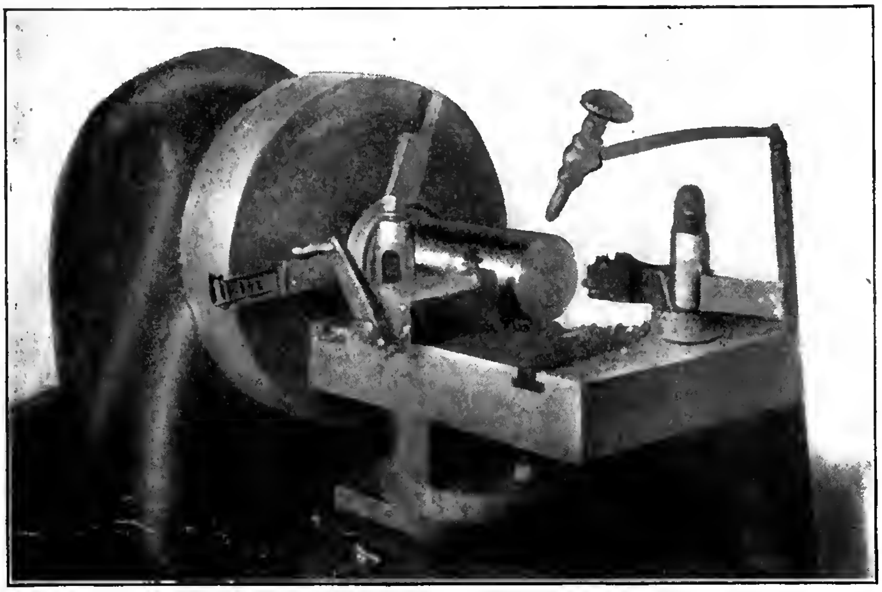
while the base is carried in a cup-shaped revolving centre on the tailstock mandril. The waving and grooving tool is situated in front, while the undercutting tools are at the back. All the tools are cutting at the same time, and the method of operation is as follows:—

The tool boxes are mounted on a fixture fastened to the lathe bed. The front tool is held in a specially-designed tool box mounted on a cross slide, the tool box working laterally in a slide. A



SHELL SHOP GALLERY SHOWING ASSEMBLY AND LOADING FEATURES.

bracket projects from the left-hand side of the tool box, and has a roller which is held up against the chuck cam by means of a strong spring at the right-hand side. The tool itself has a square face for cutting the groove with two



ROUGH TURNING SHRAPNEL SHELL BODIES.

vees for forming the wave lines. The undercutting fixture is mounted at the back, and has two tool holders, each having a hook-nosed tool. The tool holders work in diagonal slides in order to feed in at an angle to form the undercut. The tools are left and right-hand respectively and are inverted when cutting.

The feed is taken care of by cams on front and back brackets fastened to the lathe saddle. The cam on the inside of the front bracket engages with the cross slide of front tooling fixture, forcing the tool in as the saddle travels. The bracket at the back has two cams on the inside face, one for each of the undercutting tool holders. These cams also force the tools in as the saddle travels. The cam feeding in the waving tool operates on the cross slide underneath so as not to interfere with the oscillating motion of the tool box while the wave lines are being formed. This motion is imparted to the tool by the cam on chuck face.

Heat Treating.

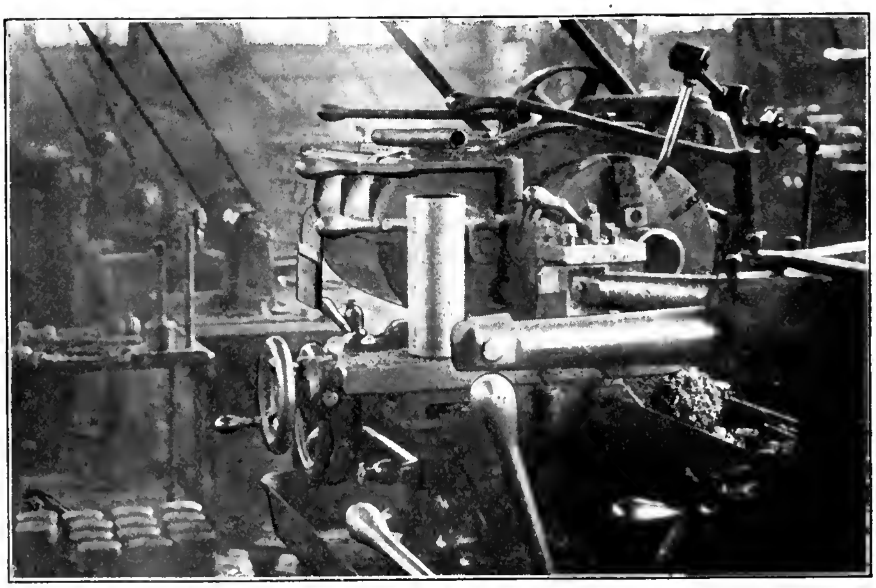
The heat-treating department is in a separate building adjoining the machine shop. In this shop is the nosing press and also the scleroscope testing bench; the furnaces are thus all together. There are four gas furnaces, not including the nosing furnaces installed—two for hardening and two for the drawing process. One furnace was supplied by the Tate-Jones Co., Pittsburgh, Pa., and the other three were built by the Collingwood Shipbuilding Co. The furnaces are heated by gas and air, no lead pot being used; the air is supplied at 2 lbs. pressure by a "Roots" rotary blower. The oil quenching tank is situated alongside the furnaces, and the oil in the tank is agitated by a belt-driven propeller to keep the oil cool. For the same purpose a number of coils with cold water circulating through them are fitted around the side of the tank on the inside.

The shells on coming from the machine shop are first of all hardened. They are heated in the furnace for about 20 minutes in a temperature of approximately 1,560 degrees Fah. They are then quenched in the oil tank and put on racks on the tank for a short time to dry. The shells are next drawn or tempered to produce the required degree of hardness. For tempering, the shells are heated in a gas furnace for about 12 minutes at a temperature around 800 degrees Fah. They are then cooled down gradually in a place free from draughts, the nose end standing in powdered lime. Previous to the drawing process, the shells are washed in a soda bath to remove the oil which clings to them after being quenched. A pyrometer, supplied by the Canadian Hoskins Co., Walkerville, Ont., is connected to all the furnaces in this department and indicates the temperature in each.

Scleroscope Test.

When sufficiently cool to handle, each shell is tested under a "Shore" scleroscope in order to ascertain the degree of hardness. By this means it is possible to tell the tensile strength of the metal, which should be approximately 80,000 pounds. The connection between the scleroscope readings and the tensile strength is that they bear a definite relation to each other, the degrees of hardness being proportional to the tensile strength of the metal. By keeping the hardness within certain limits it is possible to figure approximately what the tensile strength will be under test. This is definitely ascertained by having a test piece cut out of a shell and sent to a laboratory to be tested out on a testing machine. One shell is selected at random from each series of 120 and a suitably shaped test piece cut out of the shell at that part which has previously been tested on the scleroscope. The test piece is milled out on a milling machine supplied by the Ford-Smith Machine Co., Hamilton, Ont.

Before being tested on the scleroscope, the shells are cleaned on a polishing wheel, at the point to be tested, so that greater accuracy may be obtained in the readings. A number of the latter are taken at different points, the shell being turned round by the operator for this

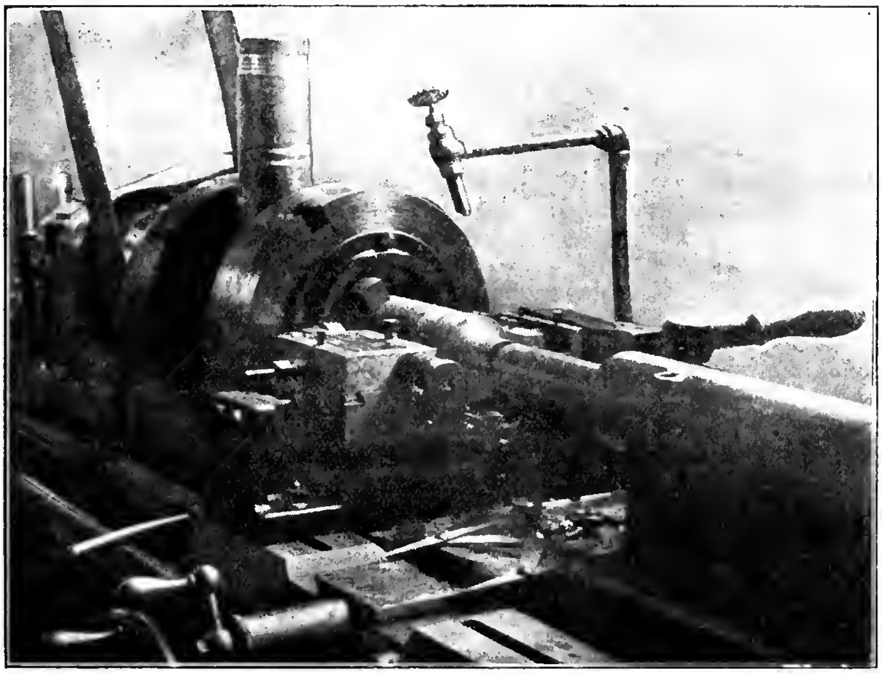


BORING POWDER POCKET AND DIAPHRAGM SEAT, FORMING OUTSIDE NOSE BEVEL.

purpose. All the shells are tested and afterwards arranged in their series.

Closing in Nose.

The nosing press is located in the heat treating department, the furnace being in line with the others and connected to the "Hoskins" pyrometer already referred to. The press was built by the Goldie & McCulloch Co., Galt, Ont., and is hydraulically operated. The lead pot is heated by gas and air, and is beside the press. The nose of the shell is heated to a dull red, then placed on the press, the steel diaphragm having been dropped in. The press is put in operation and the nose closed in by being forced up into the die at the upper end, thus closing in the nose. The shell is now taken off the press and allowed to cool slowly previous to being taken back to the machine shop.



"BERTRAM" WAVING, GROOVING AND UNDERCUTTING ATTACHMENT ON "C.M.C." LATHE.

Boring and Threading Nose, Inside and Outside Profiling.

The next operation consists of rough boring and reaming the nose preparatory to threading, forming inside profile behind the threads, rough turning nose profile outside, and cutting to length. The work is done in the foregoing order. Two engine lathes built by Flather Co., Nashua, N.H., are installed, each being equipped with a turret. After the shell is chucked, the nose is first of all rough bored by means of a cutter fixed in a boring bar held in the first turret face. A reamer now reams out the nose preparatory to threading. The third turret face holds a "Murchey" collapsible tap for threading the nose. The inside profile behind the threads is next formed by means of a forming cutter fixed to a bar held in the fourth turret face. The outside nose profile is then rough turned, a small cutter fixed in a boring bar being used. To obtain the correct profile, a roller is held in a piece projecting from the cross slide on which the turret is mounted. The roller engages with a small cam mounted on a bracket attached to the lathe bed, and, as the tool travels along, it follows the profile given by the cam. The sixth turret face holds a boring bar with a cutter for facing the shell to length.

Finish Body Turning.

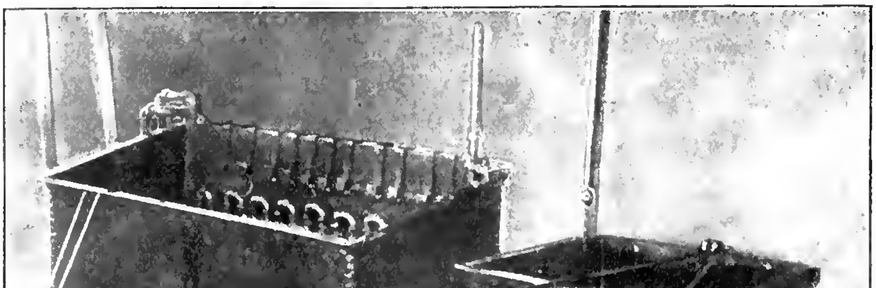
In this operation, a light cut is taken off the body and nose in a lathe and finished on a grinder. The shell is finished from the driving band groove to the end of the nose, the part behind the groove, it will be remembered, having already been finished. Three engine lathes are installed for this operation, two built by the "Canada Machinery Corporation" and one by "Flather & Co." All the lathes are fitted up in the same manner, having the same type of chuck and a forming cam under the cross slide.

The chuck is of special design and holds the base of shell behind the driving band groove. In the nose of shell is a threaded plug for the tailstock centre. A forming cam is fastened to the lathe bed under the cross slide, while a roller underneath the cross slide projects and engages with both faces of the cam. As the saddle travels, the turning tool follows the direction given by the cam, and thus forms the body of shell to the required profile.

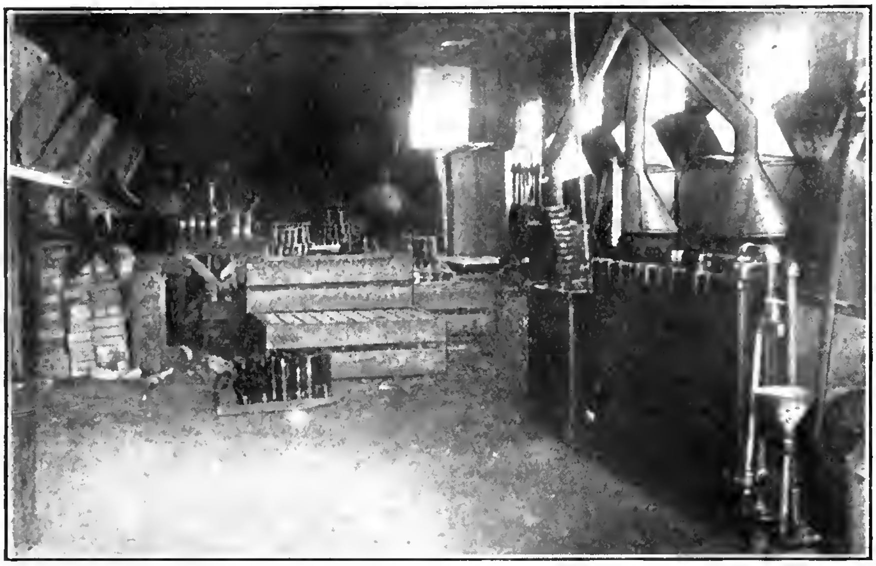
The shells are finished on a grinder built by the Ford-Smith Machine Co., Hamilton, Ont., the wheels being supplied by the Canadian Hart Wheels, Ltd., Hamilton, Ont. The base of shell is held in a chuck which has a locating stop for correct position, and the nose has the same plug screwed in as it had when being turned. The shell is ground from the driving band groove to the end of the nose at one operation, the grinding wheel being the same shape as the finished shell profile.

Copper Band Pressing and Turning.

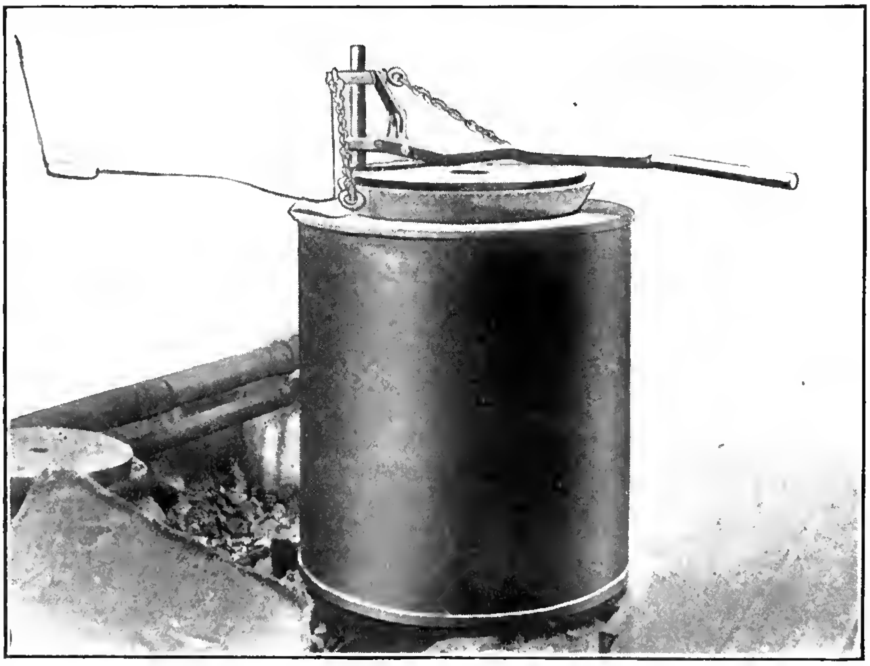
The shells now undergo a preliminary Government inspection preparatory to being taken to another department where the copper bands are pressed on and turned. The banding press was built by the "Goldie & McCulloch Co." and is operated hydraulically at a pressure of about 900 pounds per square inch. The press is of standard design, as used in many shell plants; a full description is,



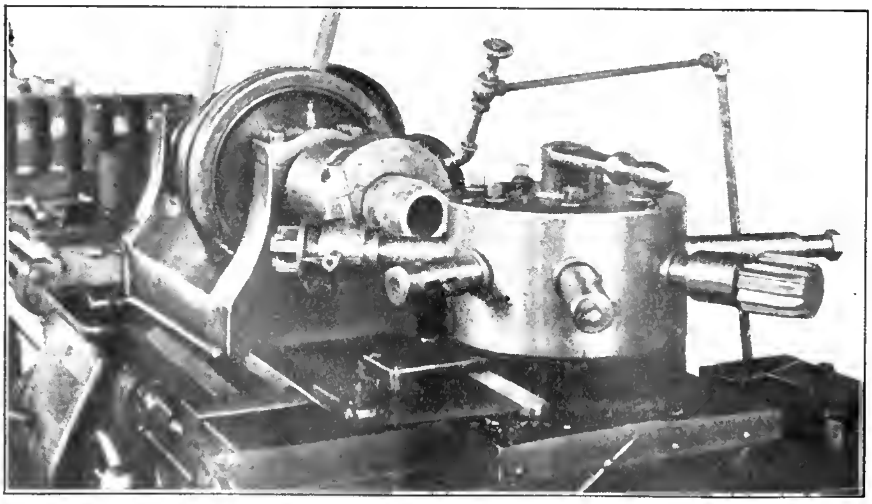
QUENCHING TANK TO LEFT AND SODA TANK ON RIGHT.



INTERIOR OF HEAT TREATING DEPARTMENT.



"TATE-JONES" GAS AND AIR FURNACE FOR SHELL-HARDENING OPERATION.



INSIDE PROFILING, THREADING AND FINISHING SHELL NOSE.

therefore, unnecessary at this juncture. In operation, the copper band is placed in the groove, the shell put on the press, and the pressure applied three times, the shell being moved around slightly after each. The band fills up the groove entirely, and is permanently in position.

The copper bands are turned on a "Warner & Swasey" turret lathe, which also has a cross slide for holding the turning tools. The turret holds a hollow centre which fits the nose of shells up to the shoulder, the centre revolving with the shell. This is the only purpose for which the turret is used. The base of shell is held securely in a collet chuck operated by a draw-back mechanism. The turning tools are mounted on the cross slide. The back tool makes the first cut, and the front tool then deepens the groove in the band, at the same time trimming the band at the edges. The back tool is set very low on the cross slide and cuts the band on the underside while travelling in a horizontal direction towards the operator, cutting the copper band as it passes underneath. This tool is of steel rolled to a special section to give the required form to the band, and only needs grinding on the cutting face to keep the cutting edge sharp. Above the back tool is mounted a gauge which projects over the work, and is used by the operator to place the back tool in the right position. The tool cannot be seen very clearly when cutting; for this reason the gauge, which is set in line with the tool, is used to place the latter in the correct position in relation to the band before beginning the cut. The front tool is set at the ordinary level, and is of special shape in order to deepen the groove in band and trim up the edges.

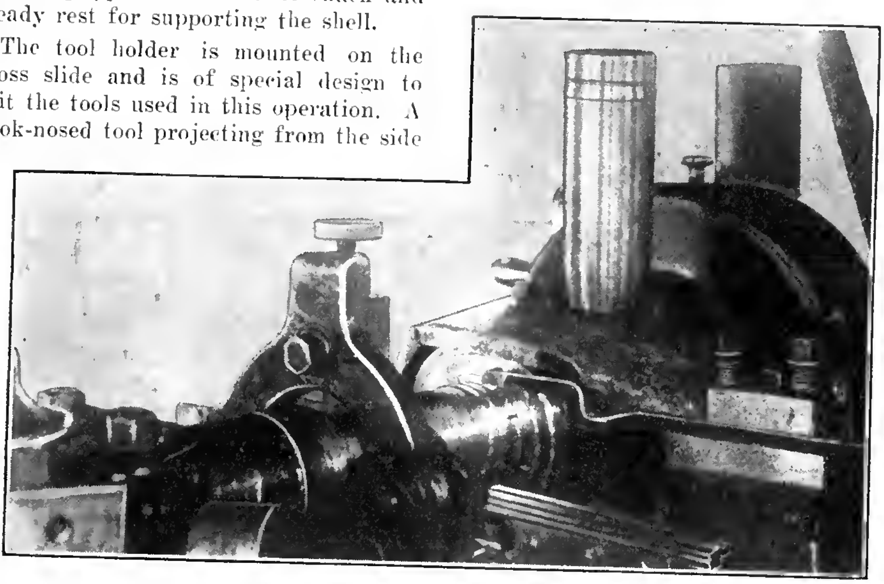
Assembling and Filling Shells.

When the shells arrive in the assembling department they are first of all hand-tapped at the nose. The tin powder cup is then slipped in past the diaphragm in the powder pocket, and the brass fuse tube screwed into the diaphragm. The shell is then placed under an overhead box or hopper containing bullets. The shell when being filled is placed on a mechanical jarring machine, which causes the bullets to settle down or consolidate. After being weighed and having had necessary adjustment made, the shells are taken over to the resin kettle and filled with hot resin, following which they are weighed again. The brass socket is then screwed into the nose, a "Chapman" ball bearing tightening nut being used for this operation. Afterwards the fuse tube is plugged with a small piece of rope, and soldered to the socket by an electric soldering iron.

Finishing Socket.

The brass socket which has been screwed into the shell nose is now finished on the outside, and the fuse seat formed. The sockets when they arrive at the plant are finished with the exception of the outside face. The fuse fixing screw hole has also been drilled and tapped. The socket finishing operation is performed on a "Flather" engine lathe, equipped with a collet chuck and steady rest for supporting the shell.

The tool holder is mounted on the cross slide and is of special design to suit the tools used in this operation. A hook-nosed tool projecting from the side of the tool holder faces up the end of the fuse tube in the socket, and at the corner of the tool holder on the front face is a small bevelled cutter which forms the socket to the same profile as nose of shell. To the right of this cutter and on the same face of tool holder is another cutter which forms the fuse seat outside the socket. After the end of fuse tube has been faced up, the tool holder is moved back into position for the other tools to be used and cross slide locked.

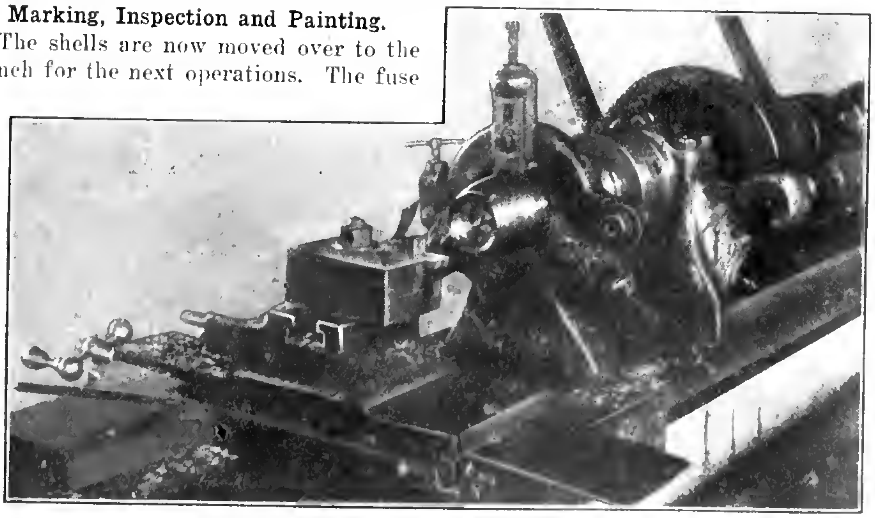


COPPER BAND TURNING.

Marking, Inspection and Painting.

The shells are now moved over to the bench for the next operations. The fuse tube hole is first reamed out with a "Hisey-Wolfe" portable air drill, and afterwards the socket and fixing screw hole are hand-tapped. The markings are put on by a "Holden-Morgan" marking machine. This is fixed on a bench, and is of the same type as is installed in several other, already described, shell plants.

After being cleaned inside with compressed air, the shells undergo the final Government inspection, during which they are weighed, gauged and carefully examined. They are then passed on to the painting department for the final operation. The painting machine consists of a cup-shaped holder on a bench attached to a vertical spindle under the bench. The spindle has a pulley attached to it, which is driven by a belt from the line shaft. While the holder is revolving, the shell is placed on it nose down and the paint applied by hand. In the centre of the holder is a spindle which goes up the fuse tube and helps to keep the shell steady while being painted. Two coats are applied, the first grey and the final coat black, the nose being painted red. When the shells are dry, a brass plug is screwed into the socket, the threads first being covered with a preparation called "luting." Packing for shipment constitutes the final operation.



FINISHING BRASS SOCKET AND FORMING FUSE SEAT.

OUR SEA POWER TRIUMPH

WRITING in the Daily Telegraph of August 18, Archibald Hurd says:

The sinking of the British transport Royal Edward in the Ægean Sea suggests not the failure but the triumph of our sea power. Not until the war is at an end will the British public realize the harassing burdens which the transport services have thrown on their Navy, which was not planned on a scale corresponding with the liabilities which were suddenly thrown on it in August, to be still further increased when it was decided to land an Expeditionary Force in the Gallipoli Peninsula

The submarine—failure as the blockade has proved—has been an embarrassment. A little over a year ago not a naval officer would, I believe, have contemplated without serious misgivings the various tasks which in the course of the war have been allotted to our naval forces.

Let no one exclaim, Why was not this particular transport better protected? That is the comment of the armchair critic, who, for his own reputation's sake, had better stick to his armchair, and not venture to sea. War consists of a series of incidents, some favorable to one side and some to the other, until the tally is complete—and then the balance is cast up, and the nation which has been the least injured is the victor.

A people which learnt in one day of the sinking of three large cruisers in the North Sea, which heard of the battleship Bulwark and the Princess Irene being reduced to nought by violent explosions, which received calmly the news of the sinking of the Ocean, Irresistible, Majestic, Triumph and Goliath, and did not lose its balance of mind when the Good Hope and Monmouth went down in honor off Coronel will not be dismayed by this latest blow.

It is a success to the enemy, but it represents no such failure to us as can exert any permanent check on our victorious movement against the foe. The ship! What does it matter? The lives? They are irreplaceable. For those who will be mourning in the next few days—after a period of anxious hopes and doubts—for the brave spirits offered up on the altar of the highest cause in which any country waged war, the sympathy not only of the nation but of the Empire will be poured out. They have died for us and those who will come after us.

The Production of Sound Ingots for Shell Requirements*

By Sir Robert A. Hadfield, F.R.S.

It is shown by the following detail of the research work carried out by the author during recent years that there is no necessity for unsound material being produced for either rail or shell purposes, slight, but highly important changes in procedure reducing losses to zero.

FIG. 1 represents two 18-in. ingots made by the Hadfield system, weighing about 2¾ tons each. These ingots were cast with the small end up, as in ordinary practice. The photograph is interesting, as it gives an excellent view of the cavity produced by the sound steel in these ingots as it settles down into the body of the ingot proper; that is, below the feeding head. In these ingots it is not necessary, in order to determine whether they are sound or not, that machining or other observation by mechanical methods should be carried out, and at least 88 per cent. to 90 per cent. of sound usable and saleable material is obtained.

Fig. 2 shows an ingot made in the present and ordinary manner; not even the most experienced expert could say whether the exterior of the ingot was sound or unsound, whereas the ingot in Fig. 1 shows the steel to have settled or sunk down. When steel so sinks it is a definite proof that the material is sound and free from blow-holes. The following results further illustrate this important advance in the production of sound steel:—

Measuring the Cavity.

To show how considerable is the cavity which forms in piping steel, nine 15-in. ingots were taken (weighing about 3,600 lbs. each), each of which had the sand head and the writer's method of feeding carried out on them. After the ingots had cooled down, the hollows or cavities in the sand heads were filled with water, then the water was poured out and carefully measured. Table I. shows the results obtained.

*Abstract of paper communicated to the Franklin Institute.

Table I.

Ingot Number.	Cubic inches.	Lbs. of Steel.	Percentage of weight of ingot.
1	457	128	3.57
2	549	154	4.30
3	457	138	3.57
4	457	128	3.57
5	472	132	3.68
6	488	137	3.82
7	518	145	3.05
8	579	162	4.52
9	488	137	3.82
Average	496	139	3.88
Maximum	579	162	4.52
Minimum	457	128	3.57

Weight of ingot, 3, 600 lbs.

The average weight for the nine 15-in. ingots showed that 139 lbs., with a minimum of 128 lbs. and a maximum of 162 lbs., passed from the head portion into the ingot itself. This percentage is represented by an average of 3.88 per cent. In other words, about 4 per cent., or 140 lbs. of of the total weight of the ingot or ingots cast passed from the upper or feeding head into the body of the ingot. Let it be assumed that the cubic capacity of each of the 15-in. ingots was approximately 12,500 cub. in. But for this feeding there would be a general want of solidity, chiefly at the upper portion of the ingot, to the extent of, say, 500 cub. in.—say, 4 per cent.—of the whole capacity. It is surely readily apparent why an ingot which is not fed must perforce be deficient in homogeneity.

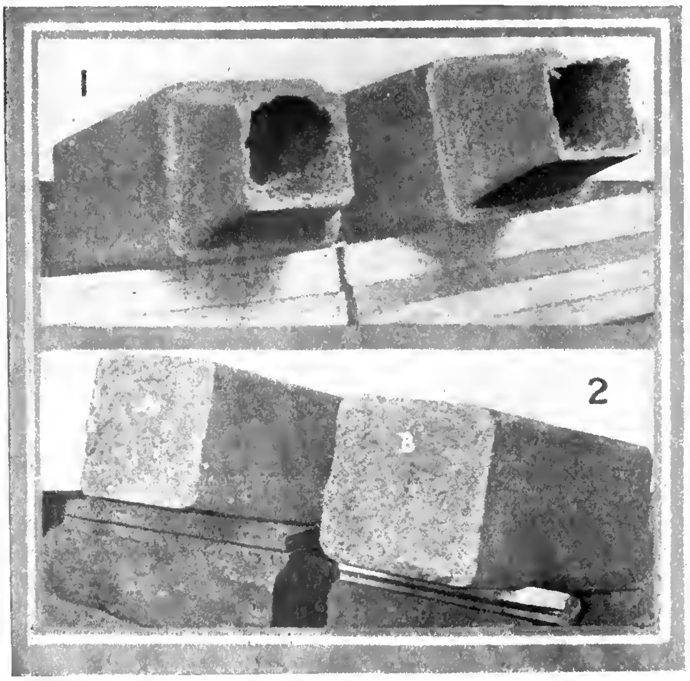


Fig. 1. 18-in. Ingots of about 2¾ tons made by the "Hadfield" process. Fig. 2. 18-in. ingots of about 2¼ tons. A—Unsound ingot. B—Piped ingot.

There is, of course, a certain amount of feeding effect from the steel in the upper portion of the ordinary ingot, but this is not done efficiently, as the steel quickly freezes on the outside of the mould and on the surface of the liquid steel exposed to the air. Moreover, there is always an uncertainty as to how good or how bad is the resulting material. In any case, as the steel solidifies in an ingot of this size, the natural law of contraction demands that about 500 cub. in. have to be dealt with on an ingot of the weight and size mentioned.

While the results necessarily vary slightly, because the sizes of the head portion nearest the top of the mould formed in sand are not always uniform in length, as the steel shrinks down slightly more on the outside in some cases than others, on the whole the maximum and minimum figures of 4½ and 3½ per cent. of the total weight of the ingot having passed from the head into the ingot itself show very uniform working; if the heads were absolutely the same depth in each case, there would be practically no difference. If not treated, the piping would have probably run down the ingot itself, requiring a discard of probably 25 to 33 per cent. Although water cannot be poured into the cavity of a red-hot ingot, yet the cavity can be determined in each ingot by a cursory examination while at a red or yellow heat, involving only a few seconds of time.

Upper Portion Defective.

While in ingots made in the ordinary way as above mentioned a certain amount of fluid steel passes from the upper portion to the lower, still in doing so, it is robbing the quality of the upper portion of the ingot itself, which has no fluid metal above it to feed or take the place and supply the deficiency thus created. It will readily be understood, therefore, why the upper portion of ingots is so seriously affected as regards their soundness, also why segregation occurs. This is shown in a remarkably clear manner by ingot B (fig. 4). The steel in the "fed" ingots being maintained fluid in the head portion continues to exercise its ferro-static pressure, whereas with ingots made in the ordinary way the ferro-static pressure on the centre portion of the ingot is so slight that it produces very little beneficial effect. Further, without the feeding head above the ingot proper, the outside of the ingot in the ordinary ingot mould becomes rapidly chilled and frozen, so that it cannot contribute its proper share to the feeding of the remaining portion of the ingot. It is not, therefore, to be wondered at that rails rolled from the A and B portions of an ingot made in the ordinary way are liable to unsoundness or piping, or both, and are also often full of impure segregated material. There would probably be more dangerous ingots but for the fact that the steel maker tries to avoid this type of steel, and aims to make steel which will not pipe when poured into the ingot. Nevertheless, he is still fighting against a natural law. If piping steel is checked or avoided, he runs the risk of producing unsound steel, especially in the upper portion of the ingot, more or less permeated with blowholes. Thus, owing to lack of feeding from the upper portion, the centre, or that portion on the axis line of the ingot, must be of inferior nature, as the piping characteristics persist for quite a long way down the ingot.

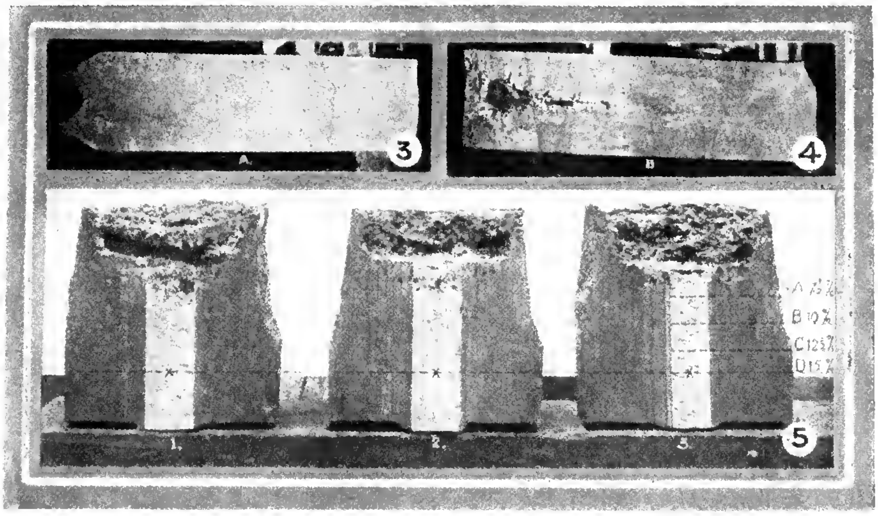

Fig. 3. Ingot made by "Hadfield" process; perfectly sound, free from blow holes, piping and segregation. Fig. 4. Ingot made in ordinary manner; unsound, having blow holes, piping and segregation. Fig. 5. Upper portions of three ingots made by the "Hadfield" process.

Ferro-Static Pressure Necessary.

This, as before mentioned, is for the reason that, owing to want of ferro-static pressure, the ingot lacks feeding from above, which, in the system of casting ingots now described, is maintained to a very late stage; that is, until or close upon actual solidification. There is always fluid steel in the upper portion of the ingot to feed the piping and shrinkage, both of which must occur, as they follow a natural law. Check or hinder ferro-static pressure, and segregation with its bad effects at once commences. In the case of "fed" ingots, the smaller amount of segregation which occurs takes place outside the ingot proper; that is, in the head.

The experiment, carried out by the writer some years ago, of pouring copper into the upper portion of an ingot 15 or 20 minutes after casting, showed how serious is this want of ferro-static pressure in the material situated on or near the centre or axis line of the ingot in ingots which have not been properly fed. The copper finds its way down to the bottom of the ingot, although added 15 minutes after casting. In any case, if there is no definite pipe at the bottom portion of such ingot, there is still material of loose or open structure, which means weak steel. Although this may not be apparent by fracture to the naked eye, nevertheless it exists, and can generally be detected by an examination of the micro-structure. In other words, notwithstanding that the product to be used may come from the lower half of the ingot, yet in unfed ingots it will be weak and not able to stand severe stresses.

It is true that some portions of the cavities in ingots have been measured, but probably not in the manner described by the writer. Although in the examination of the top of an ingot cast in the ordinary manner, and from steel which "settles" there is external evidence of some piping, this is irregular and varies considerably. Therefore, in the "best" ordinary ingot evidence is slight as to how much or how little the steel has piped.

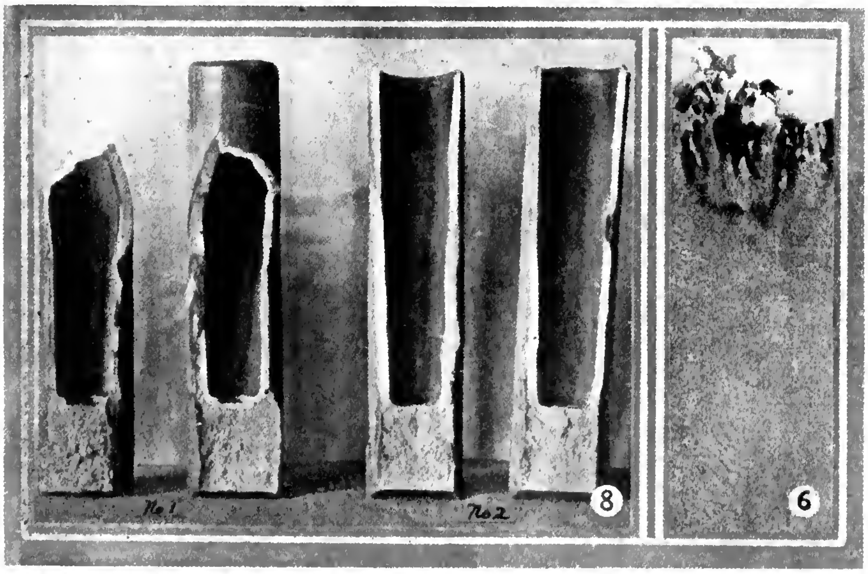

Fig. 6. Etching on axis line to determine amount of segregation. Fig. 8. Shell forgings from blanks (1) and (2) of Fig. 7, split open for inspection.

Kinds of Piping.

Dr. Dudley has pointed out that such piping is divided into two kinds: the upper, or what may be termed the visible pipe, and the lower or hidden pipe, the extent and character of which can be determined only by cutting open the ingot. In the ingots cast under the writer's system, all the cavity or pipe is open and can be rapidly inspected from

the top, its extent can be readily determined whether in the hot or cold condition. It is therefore not necessary to cut open the ingot.

Dr. G. K. Burgess, of the Bureau of Standards, Washington, is at present working with the writer on a joint research relating to this subject, and, though the full details of the work done cannot at the present time be given, it may be stated that ingots made under the writer's system were carefully cut up by the Bureau and compared with similar ingots produced at rail mills and made in the ordinary manner. The comparisons are shown in Figs. 3 and 4, in which A (Fig. 3) represents the ingot made under the writer's system, as described in the various papers, and B (Fig. 4) represents an average ingot made by one of the rail-makers.

Piping Defects Incurable.

While it is true that in unsound steel of very mild character the process of forging or rolling closes up the blowholes, and probably, if the heating temperature for rolling or forging is hot enough, the blowholes are welded together, even then it is doubtful whether such material can ever afterwards possess exactly the same tenacity and ductility as the same steel worked up from a sound ingot. In the case, however, of rail steel in which the carbon percentage is high, the same amount of welding does not take place; in fact, it is doubtful whether the blowholes are more than merely pressed together.

Sound Steel Imperative.

As large quantities of high-explosive steel shell are used by various governments, it is most necessary to obtain steel of the highest quality and yet at not too high cost. In other words, there is required steel of superior quality to that ordinarily used for rails, ship and boiler plates, angles, bars, etc. The system of manufacturing ingots of sound steel, described in the present paper, exactly meets these special requirements. Moreover, it can be used for making the comparatively lower quality of steel referred to. Several important governments, after making exhaustive tests, have been so satisfied with the Hadfield system of making sound ingots that, both for their land and sea services, they have now authorised explosive shell being made from ingots (afterwards forged into necessary billets) produced in the manner described in this paper.

As will be understood, an explosive shell, whether of small or large calibre, must be absolutely safe; that is, it must be (a) sound (that is, free from blowholes); (b) free from pipes; (c) free from segregation. Any flaw in the shell to its premature bursting would be most disastrous. In order to be absolutely certain of obtaining this combination of desirable qualities, it has been insisted upon by the user concerned that something like 40 per cent. to 50 per cent. of the ingot made in the ordinary manner—in fact sometimes more than this—must be discarded. Ingots made by the writer's method, however, are now allowed after discarding only 15 per cent.

It would also be quite possible under the system to give perfectly safe shell steel with only 10 per cent. to 12 per cent discard, and to ensure the qualities under the headings (a), (b) and (c) just referred to. This means a reduction in discard from 40 per cent. to 15 per cent. This decision has been arrived at after carefully cutting up and examining over one hundred ingots made by the Hadfield system, produced in the ordinary course of working. Each of these ingots on being cut up, was found to be perfectly sound.

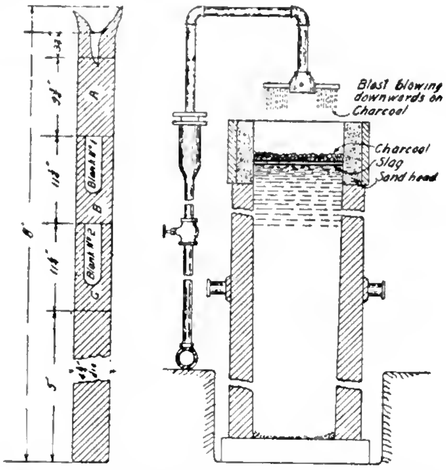

Fig. 7. Sketch showing upper portion of ingot forged and drawn out into a bar 4¾ in. diar. and about 8 ft. long. Fig. 9. Apparatus employed in producing sound ingots.

were not satisfactory the ingot would be rejected.

Ascertaining Soundness of Ingots.

The following demonstration was made to show the importance and efficiency of the system:—Fig. 5 shows the upper portion of three 15-in. ingots made under the Hadfield system. This place shows the soundness and freedom from piping of the ingots. If this is compared with the section of the ordinary rail ingot shown in B (Fig. 4), representing average and current practice, it will be seen how great is the difference. While sound material, whether rails or other articles, can be expected from ingots made as shown in Fig. 5, it can be well understood that if steel for explosive shell were made from an ordinary steel ingot cast in the usual manner, as shown in B (Fig. 4), there would have to be at least 50 per cent. discard in the ingot, and even then it is doubtful if the material could be safely used.

To further prove this, Fig. 6 shows an etching of the fractured portion of a 15-in. ingot (marked No. 3 in Fig. 5), on the centre or axis line, where segregation is usually met with to the greatest extent. This being so sound and free from segregation, it was necessary to continue the etching beyond the fractured portion. The analysis of this particular 15-in. ingot is shown in Table II. From this table it will be seen that there are no signs of segregation, unsoundness, or piping of any kind until the extraordinarily small discard of 7½ per cent. has been reached. Even in this case the difference in composition is very slight, whereas the composition of an ingot made in the ordinary manner and with only 7½ per cent. discard, to say nothing of the unsoundness, would show probably 0.60 to 0.70 per cent. carbon and 0.07 per cent. each of sulphur and phosphorus.

Table II.

	Analysis.				
	C.	Si.	S.	P.	Mn.
Original steel	0.36	0.19	0.031	0.031	0.96
A. Discard of 7½ per cent. (sand or feeding head of ingot)	0.54	—	0.056	0.031	—
B. Discard of 10 per cent.	0.46	—	0.040	0.031	—
C. Discard of 12½ per cent.	0.39	—	0.040	0.031	—
D. Discard of 15 per cent.	0.39	—	0.033	0.031	—
E. Bottom of ingot	0.38	0.19	0.031	0.031	0.96

It should be remembered that steel produce from the ingots to be used for the requirements of various governments is most critically examined by many inspectors supervising the material produced and the work done, not on the ingot only, but on each projectile, also including a considerable number of mechanical tests from each ingot, and from a certain number of projectiles made from each ingot. Moreover, each individual ingot is cut up and has to be passed on its own discard; if this

Table III. shows a number of analyses taken during the ordinary course of working) that is, they are not in any way special) from the centres of different ingots as above described, the drillings for analysis being taken exactly at the parting line where the 15-per cent. discard has been made. The figures obtained clearly show the important fact that the

steel is as pure and free from segregation at this part as it is at the bottom or at any other portion of the ingot.

As a further test, the following interesting experiment was made:—The portion of one of the ingots representing the usual 40 per cent. of the discard hitherto demanded in the manufacture of high-explosive shell was taken from an 11-in. ingot having the following analysis:—C, 0.38 per cent.; Si., 0.18 per cent.; S, 0.024 per cent.; P, 0.035 per cent.; Mn., 0.85 per cent. This was forged into bar 4¾ in. in diameter and about 8 ft. in length, as shown by Fig. 7. Projectiles were forged from this bar as indicated.

The length marked A is the portion of the material from the top part of the ingot head which, in the writer's system is cast in sand; that is, above the ingot itself. This portion, about 13 in. in length, and representing 7.1 per cent. of the discard, was cut off. Below this the projectile forging known as "Blank No. 1" was prepared, as shown by the dotted lines in Fig. 7. Below this, "Blank No. 2" was taken after 10.4 per cent. discard had been allowed. In other words, "Blank No. 1" was made from the material now not used (that is, after 7.1 per cent. of the whole ingot was discarded) and "Blank No. 2" after discarding 10.4 per cent. This is also not now used. The further and following blanks, No. 3, 4, and upwards, are not shown, because this is unnecessary, as such blanks then formed part of the current work. As will be seen, even "Blank No. 2" could also have been safely used.

It is remarkable to find that the fracture from "Blank No. 1" (that is, at the discard of only 7.1 per cent.) was perfectly sound, free from piping, and showed no signs of segregation. In the interior of the blank, after forging, there were some slight skin cracks proceeding from the hollow portion of the ingot top. The projectile from "Blank No. 2" was perfectly sound in every way, whether as regards surface fracture, freedom from segregation, piping, or any other defects; the interior was also perfectly sound. In other words, from this "Blank No. 2" (that is, with only 10.4 per cent. discard) a perfectly sound projectile was obtained.

The two projectiles from "Blanks Nos. 1 and 2" after being split open, are shown in Fig. 8. It will be seen that the fractures are sound, and that in each case, even including the blank from the portion of the ingot with only 7.1 per cent. discard, the material would have etched quite sound and free from segregation. The writer has now produced close upon 40,000 tons of ingots by the plan referred to in this paper.

Description of the Hadfield Process.

The following is a description of the author's method of casting steel ingots, castings, etc. which ensures soundness, freedom from piping, and absence of segregation: The process is illustrated in Fig. 9. As will be seen, it consists in heating the fluid steel in the upper part of the ingot or other mould, and maintaining it in a liquid condition by the combustion, in contact therewith, or in close proximity thereto, during the cooling and shrinkage of the metal in the lower part of the mould, of solid fuel, for example charcoal, by means of a blast of compressed air which is caused to impinge on the fuel while this is directly or indirectly supported by the metal below; and the interposition of a layer of fusible material, such as cupola slag, which has little or no injurious action on the metal, between the metal and the fuel. This slag largely prevents radiation of heat, the loss of which is much greater than is ordinarily supposed to be the case.

MUNITION METALS.

A PREPONDERANCE of raw material from which to manufacture munitions of war is of vital importance to a belligerent, and if, as many persons hope, the allies can maintain the advantage in this respect at the expense of the enemy, the raw material assumes a doubled value. Professor H. C. H. Carpenter, writing to "Nature," compares the resources of the different countries in munition metals, and sums up the position as follows:—

Belligerent Resources.

Of the ten munition metals, the enemy countries can certainly produce five without having resource to imports—namely, iron (the basis of the various steels used for war purposes), manganese, chromium, zinc, and lead; on the other hand, it is doubtful whether they can produce sufficient nickel, copper, aluminium, tin, and antimony from domestic ores. In view of the fact, however, that they prepared for this war with extreme care and foresight, it may safely be concluded that large stocks, either of ores or the corresponding metals or both, will have been accumulated in those countries.

However confident the higher German command may ostensibly have been of a rapid victory, they will quite certainly have laid their plans to wage a prolonged war if it should prove to be necessary, and such plans will have included the accumulation of munition ores and metal of which their countries produced an insufficient amount. There is, accordingly, no adequate reason for concluding that the enemy countries are likely—in spite of the prodigious scale upon which the war is being conducted—to run short of metals which are essential for war purposes for some time to come. Moreover, it may safely be concluded that their technical metallurgists will have been mobilized in the direction of discovering substitutes for any of the above metals of which a shortage is liable to occur in a long war.

The allies for their part can produce from their own resources all the iron, manganese, nickel, chromium, tin, and most of the aluminium they require; their command of the seas enables them to obtain, principally from the United States, their deficiencies in aluminium, copper, and lead; China furnishes the requisite antimony. Zinc is the only important munition metal of which there is a shortage, in spite of the great speed with which the American furnaces are being operated. Wherever it is possible to substitute another metal for zinc, it is of national importance that it should be done.

PROGRESS IN NEW EQUIPMENT

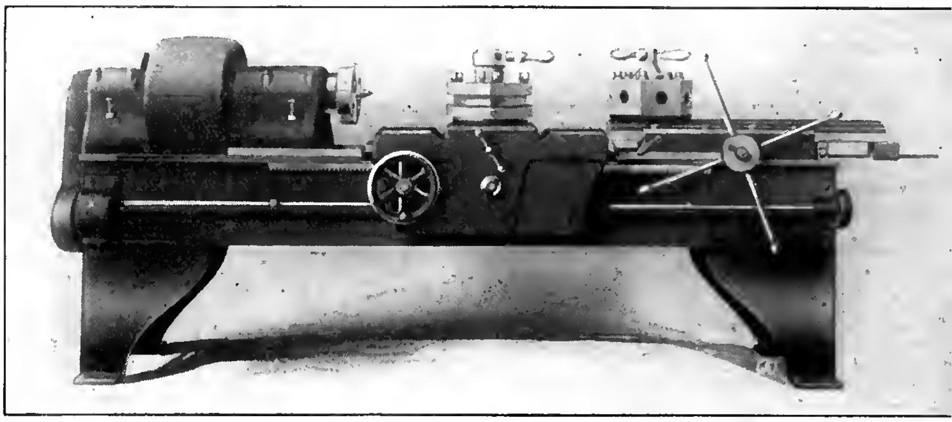
A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

SINGLE PURPOSE SHELL LATHE

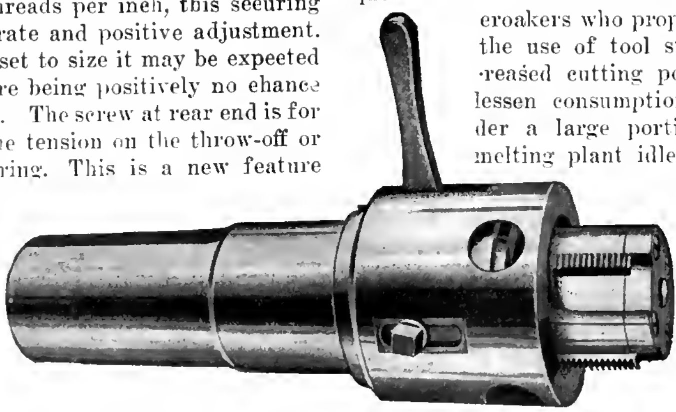
THE description and illustration refer to a new "Made in Canada" lathe which is being put on the market in response, we understand, to the demand for a heavy, sturdy tool with suitable attachments for producing the various machining operations required in shell work. This lathe is specially designed for the latter and is complete with all attachments necessary to rapid production of completely machined shells. Strength, rigidity, and weight, and a large swing just sufficient for the purpose for which it is designed, are the leading features of this product. The two sizes in which the lathe is to be built are reckoned to amply cover the requirements for machining shells up to and including 12 in., and the general scheme of manufacture is aimed to satisfy the present keen demand for quick delivery. The exclusive Canadian distributors of the lathes are Kellogg & Co., Traders Bank Building, Toronto.

COLLAPSIBLE TAP FOR SHELLS

THE accompanying cut shows the "Victor" collapsible tap which has been specially designed to tap shrapnel shells. It is made of a tough grade of machinery steel so as to stand the strain of hard usage. The tap is adjusted from the front end by means of a hardened setscrew, 32 threads per inch, this securing a fine, accurate and positive adjustment. When once set to size it may be expected to stay, there being positively no chance for slipping. The screw at rear end is for adjusting the tension on the throw-off or tripping spring. This is a new feature and a desirable one. All parts of the tap subject to wear are hardened and ground. The object in designing this tool was to make a tap that would cut threads accurately, and have sufficient strength and durability to make it an economical tool for the shell maker. The chasers are made of the best grade of high-speed steel; they are strong and heavy, and will stand the strain of threading shrapnel or high-explosive shells. This tap may be used in a turret head or attached to a live spindle, working satisfactorily in either condition. It is manufactured and sold by the Victor Tool Co., Waynesboro, Pa.



NEW SINGLE PURPOSE SHELL LATHE.



COLLAPSIBLE TAP FOR SHELLS.

THE ALLOYS OF HIGH-SPEED STEEL.

NO subject probably is receiving more attention in the steel trade of Sheffield to-day, says a correspondent of The Engineer, than that of alloys used for making high-speed steel. Since the discovery that certain rare metals gave to high-speed steel its essential property, and also the method of applying them successfully in manufacture, the trade in question has been revolutionized. The croakers who prophesied that the use of tool steels of increased cutting power would lessen consumption and render a large portion of the melting plant idle have been completely discredited. Although the modern variety of steel will do treble the work of the old, there has been a big increase of demand and output, and makers have enjoyed a measure of prosperity never dreamed of before.

Metallic Tungsten Production

With these facts in view, one can appreciate the anxiety that is felt on the subject of the supply of ingredients, without which high-speed steel cannot be produced. For metallic tungsten, the most important of them, the trade had for years relied upon the German metallurgical chemists to keep it supplied, but the war has taught it a sharp lesson in the necessity of being in a position to meet its own needs, or at any rate, not to be dependent upon a single source. Whatever happens in the future, it is certain that an adequate supply of tungsten is assured, and the question of whether Germany ever resumes its premier position in the manufacture of the alloy is of secondary importance. Germany may influence the market, but it will never again control supplies. Half a dozen works in England are engaged in its manufacture, several of them turning out the alloy in its metallic form, which is preferred by the local users.

The production of the latter is the great problem facing the trade. There is a large and ample output of ferro-tungsten, but to make the metal of the high standard of purity required in the form of metal necessitates much experiment and experience. Four firms are grappling with the problem. One of them is sending out considerable quantities. A second has supplied a small quantity of the right quality, and a steady increase is promised until a maximum of some 30 tons a month is reached. That, we believe, exceeds the output of any of the German works in the past. Hence on the completion of the experiments and developments now in hand, steel makers will be under no necessity to go outside the country to get supplied. The factor of price may, of course, arise, but there is no reason to doubt that British makers will be in a position eventually to hold their own against Germany even in this matter.

EXPLOSIVES AND GUNS.

THE establishment of factories in Canada to manufacture high explosives from raw material produced in the country, marks another step forward in the ammunition industry of this country. Cordite, which forms the propelling agency in British shells, is of special interest to thousands of Canadians engaged in shell making. This material gets its name from the form in which it is produced. It is a mixture of gun-cotton, nitro-glycerine and a mineral jelly. The jelly is employed to convert the gun-cotton into a plastic substance which can be squeezed or rolled into any form desired, but which becomes hard and horn-like when dried. When the material is in a suitable state it is put into presses which squirt it through dies of the required size suitable for any bore of rifle or gun.

Rifle cordite is produced in the form of a thin cord, and is wound on a reel; the thicker forms of cordite for guns are cut into suitable lengths. The final stage of manufacture is drying, which takes as long as two months in some cases.

John B. C. Kershaw, writing in Cassiers' Engineering Monthly, makes the following interesting statements on the subject of modern explosives:

The required muzzle velocities and pressures for rifles and guns can be obtained, with variations that are exceedingly small. Thus for rifles, the velocity prescribed is 2,380 foot-seconds with a plus or minus of only 40 feet, and a pressure of 19.5 tons with a maximum of 20 tons per square inch; for larger guns it may be 1,500 foot-seconds, and the pressure must not exceed 19 tons per square inch.

Application of Explosives in Warfare.

Great developments have occurred in the application of explosives to warfare during the last thirty years, for the introduction of elongated projectiles, rifled guns, and high explosives has practically revolutionized land and naval warfare. It is difficult to realize now that at the battle of Waterloo the effective range of cannon was less than 2-3rds of a mile, and that as solid iron balls were employed, the destructive effect of artillery fire was confined to the individual or building hit. One round from a modern field-gun firing a 3-inch shell, in fact, will do more material damage, and kill or wound more men, than twelve hours' firing with the form of cannon used in 1815. It is also a fact that when the Dardanelles were last forced by a British fleet (in 1807) the Turkish guns were firing stone shot, and that in Nelson's day, naval actions were rarely commenced at a range of more than one thousand yards.

Explosives are divided into two distinct classes known as "high" explosives and "low" explosives, the chief function of the latter in warfare being as a propellant, while that of the former is to destroy life and fortifications, by the shattering effects of the explosion, which occurs when they are detonated. "Low" explosives, as a general rule, are employed in the form of cartridges in order to generate a steadily increasing force in the chamber of the rifle or gun, sufficient to project and carry the bullet or shell to its mark. "High" explosives are employed in a casing or canister of steel, and are detonated either by a time-fuse, or by percussion on striking the ground or the object aimed at.

The weight of the shell differs according to the size of the gun; that fired from the ordinary 3-inch field-gun varies in weight from 15 to 18½ pounds. An explosive shell differs from shrapnel in that it contains no bullets, and the damage done by it to buildings and human beings, when the charge is detonated, is due to the force of the explosion and to the flying fragments of the steel case when it bursts. The detonator employed for high explosives is fulminate of mercury mixed with potassium chlorate and enclosed in a copper container.

Types of Guns.

The quick-firing 3-inch field-gun is the most important weapon used by the opposing forces, and it is estimated that Germany at one period of the war had 5,000 guns of this type in the field. The German gun is a converted breech-loader, and fires a 15-pound shell with a muzzle velocity of 1,525 feet per second. It is light and of simple construction, but possesses several disadvantages which render it a second-class gun.

The French 75-millimeter and the English 3-inch field-guns are of more modern type than the German gun; the rate of firing can be maintained at 20 rounds per minute, if desired, for a short period. The English gun fires a shell weighing 18½ pounds, whereas the French gun fires a shell of 15 pounds with a muzzle velocity of 1,740 feet per second. The Allies' 3-inch field-guns are superior, therefore, in range, accuracy and firing speed to the German guns, and it was only by their greater number that the Germans gained many of their successes in the early stages of the war.

It is reported that the Germans have developed a new type of field-gun which is fed automatically with shells on the machine-gun principle, and that this gun can fire double or treble the number of shells per minute that was possible with the older pattern. This new weapon, it is stated, will be used against the Allies on the Western battle front, and time will show how far the claims for the new gun are substantiated.

The Howitzer.

A howitzer, it may be explained, is the short, heavy type of gun used for throwing shells at a high angle in order that they may fall vertically into the enemies' lines or entrenchments with a high striking velocity. Both the Allies and the Germans have been making great use of this type of gun in their attacks in Flanders and Northern France. The British field howitzer fires a 4.5-inch 35-pound shell, and has a range of 3,400 yards. The German weapon of this class is 4 inches in diameter and fires a shell weighing 31 pounds with a muzzle velocity of 985 feet per second. The projectile fired by this latter howitzer is shrapnel charged with bullets embedded in tri-nitro-toluol, and this is the shell which has accounted for many casualties in the British and French lines.

The British army in addition to the light field-howitzer, possesses a heavier gun, throwing a 60-pound shell with a range of 9,500 yards; while opposed to this the Germans have a 6-inch howitzer throwing a 90-pound shell, and capable of firing at an elevation of 65 degrees. The range to which a shell carries is, of course, diminished as the angle of fire is increased above 45 degrees, and the object of firing at such an acute angle as 65 degrees is to obtain a steep angle of descent, and to ensure penetration of any overhead cover by the shell when it strikes the ground.

Although it is not generally recognized, it is a fact that the application of explosives to warfare in the past has tended to keep the opposing forces far apart, and to diminish the amount of hand-to-hand fighting. This tendency has resulted in diminished casualty lists in proportion to the numbers engaged in conflict, for it is only when engaged at close quarters in hand-to-hand fighting that the proportion of killed and wounded in armies can rise to fifty or more per cent.

This stage of warfare appears, however, to be passing away, and with the development of trench warfare and the use of poisonous gases, in addition to hand grenades and bombs filled with high explosives, we are once more confronted with conditions of combat which resemble those of earlier time. How far this development will proceed it is impossible to say. The powers of destruction that have been placed by the advances of science in man's hands are terribly effective, and it is quite possible that the limit has not even yet been reached.

Machinery Display at the Canadian National Exhibition

Staff Article

Machinery and supplies exhibited are particularly interesting in view of the peculiar conditions which have existed during the past year. Exhibitors are to be congratulated on their efforts to maintain the former high standard of equipment display. Progress in standard lines, and much that is new in special lines, are the two features which impress the visitor,

THE disturbing influence of the war is not so apparent as might be expected in the display of machinery and kindred equipment in the Machinery Hall and elsewhere at this year's Canadian National Exhibition in Toronto. A number of former exhibitors are unable to be present, but their places have been filled by several new comers, the variety of whose product augurs well for the future of the Canadian machinery industry.

Interesting Exhibits

The A. R. Williams Machinery Co. are to be found in their familiar location. Shell machinery and a "Williams" quick-firing field gun give quite a war-like atmosphere to the exhibit.

Cowan & Co. make their usual interesting exhibit of woodworking tools and machines, while the Preston Woodworking Machinery Co. show a tenoning machine in addition to their last year's products.

The Chapman Double Ball Bearing Co. exhibit a "Perrin" hydraulic pump and press in operation on actual shells destined for the battlefields in Europe. The Dodge Mfg. Co. are receiving visitors at their exhibit, which contains numerous examples of their widely-known products.

The Victor Saw Works, Hamilton, Ont., have two power hack saws working on shell material which make the exhibit attractive as well as instructive.

The Pratt & Whitney Co. show a special set of small tools for shell manufacture, while the Carter Welding Co. have a machine in operation, and carving armor plate quicker than the ordinary person can saw wood. L'Air Liquide Society again show the samples of work done by their apparatus in the welding and cutting metals.

At the Canadian Ice Machine Co. stand is a domestic ice box of ordinary proportions which is equipped with a complete automatic self-contained refrigerating plant of 1½ horse-power capacity in operation. A further anti-heat demonstration is in constant operation at the exhibit of the Armstrong Cork & Insulation Co., where the benefits due to the use of their "Nonpareil" Insulating Brick are made evident through the use of an electric furnace.

Belting exhibits are staged in an effective manner by the Dominion Belting Co., Hamilton, Ont., and D. K. McLaren, Ltd., Montreal, while the many excellent features of the Elliot Wood Worker are again demonstrated under actual conditions of use.

Machinery Hall

Armstrong Cork and Insulation Co., Toronto.—Electric furnace in operation, demonstrating insulating power of "Nonpareil" insulating brick, specimens of diatomaceous earth, cork products, etc.; models of insulated furnace settings. Representatives: G. C. Albertson, J. Kent.

Aylmer Pump and Scale Co., Aylmer, Ont.—Hand and power pumps, scale trucks, domestic water supply systems.

L'Air Liquide Society, Toronto.—Demonstrating oxy-acetylene welding: hand and power welding machines, acetylene generators, specimens of work, etc. Representatives: A. Turnbull, M. Harch, N. Smith.

Boiler Repair and Grate Bar Co., Toronto.—20th Century Grate Bars; "Coppus" Steam Turbo Blower for chimney draft. Representatives: C. W. Andrews, A. H. Hetts.

British Aluminum Co., Toronto.—Aluminum products, samples of bauxite, cryolite, aluminum powder for bombs, etc. Representative: E. Pannel.

Baines & Peckover, Toronto.—Exhibit of "Triumph Superb" tool steel: crucible, vanadium and cold rolled steel; expanded metal, babbitt metal, chain, wire rope, etc. Representatives: W. M. David, T. A. Steven, H. W. Marshall, A. McGregor, W. P. Williams.

The Canadian Automatic Wrench Co., Toronto.—"Dickson" automatic pipe and nut wrenches. Representatives: H. L. Dickson, J. Henderson, Fred C. Fowler.

Cowan & Co., Galt, Ont.—Two chain morticers, power feed rip saw, four side molding machine. Representatives: W. Cowan, S. F. Barrows.

Canadian Mill Supplies and Steam Specialties, Ltd., Toronto.—"Morehead" back to boiler system, United States graphite preparations, "Griscom-Russel" heaters and generators, "Everlasting" blow-off valves. Representatives: J. G. Abraham, L. O. Smith.

Cling Surface, Buffalo, N.Y. — Apparatus demonstrating the efficiency of slack belt drives when treated with "Cling Surface." Representative: J. B. Faatz.

Cleveland Pneumatic Tool Co., of Canada.—New Cleveland stope drills, portable foundry grinding machines, and a full line of pneumatic hammers, drills, riveters, Bowes and

CANADIAN NATIONAL EXHIBITION SHOWING SECTION IMMEDIATELY BEHIND MAIN ENTRANCE.

Neverleak couplings, etc. Representative: J. A. Day.

Canadian Ice Machine Co., Toronto.—Domestic refrigerating plant in operation, installed in Arctic refrigerator. Various sizes of York ice machines, apparatus and fittings, etc. Representatives: C. E. Allison, C. H. Bower.

Canadian General Fire Extinguisher Co., Toronto.—Demonstration of automatic sprinkler system in operation. Control apparatus for both wet and dry systems, sprinkler heads, fittings, etc. Representatives: W. Roos, W. Kay.

Carter Welding Co., Toronto.—Davis-Bowmanville oxy-acetylene apparatus, generators, blowpipes, armor plate cutting demonstration, etc. Representatives: H. W. Carter, P. Sorley.

Canadian Pneumatic Tool Co., Montreal — Pneumatic tools and fittings.

Geo. W. Cole Co., Torooto.—Cole heaters, boiler feeders and steam specialties. Representative: G. W. Cole.

Canada Machinery Corporation, Ltd., Galt, Ont.—Woodworking tools, viz: 48 in. band resaw, tenoning machine, 32 in. knife grinder, sash mortiser and relisher, hollow chisel mortiser, chain mortiser, New Pattern light variety saw bench, set of sample knives; ironworking tools, viz.: 36 in. vertical drill, 25 in. vertical drill, 24 in. backgeared crank shaper, No. 19 geared power press. Representatives: D. King, P. V. Burton, W. J. Irving, M. Preston.

Chapman Double Ball Bearing Co. of Canada, Ltd., Toronto.—"Chapman" elevating trucks for factories and warehouses. Shell machinery in operation. Complete line of ball bearings for all purposes. Illuminated display board. Representatives: W. J. Murray, C. M. Murray, W. C. Hockin and H. O. Edwards.

The Dodge Mfg. Co., Toronto.—Complete line of transmission machinery, including steel and wood pulleys, bearings, hangers, etc. Representative: J. F. Haas.

Dominion Belting Co., Hamilton, Ont. — Maple Leaf stitched cotton duck belting for power transmission and conveyors. Representative: J. Scott.

Len Edmonds, Smiths Falls, Ont. Maple sugar evaporators and supplies for the industry made by Small Brothers.

Elliot Wood Worker, Ltd., Toronto.—No. 3 machine with tilting table and graduated index plate for revolving, wood drilling machine, scroll saw and shaper. Representative: W. A. Elliot.

General Machinery Co., Toronto.—G.M.C. automatic water systems; demonstration of Luitweiler pumps. Representative: W. McLachlan.

G. Walter Green Co., Peterborough, Ont.—Woodworking machinery and saws.

The Holden Co., Montreal.—Complete line of portable electric and air tools, rock drills and railway supplies. Representative: J. B. Wilson.

The Hare Engineering Co., Toronto.—Full size installation, demonstrating the operation of the Fulton water-cooled mechanical stoker. Terry steam turbines, and Swartwout steam separators. Representative: J. F. Wood.

Jones & Glassco, Ltd., Montreal.—One 150 horsepower "Renold" silent chain drive, one 60 horsepower "Renold" roller chain drive.

Jones & Moore, Toronto.—Full line of electric motors, for 1, 2 and 3 phase and direct current. Shoe finishing machinery in operation. Representative: W. Dalton.

D. K. McLaren, Ltd., Montreal.—British oak tanned belting, D.K. balata belting, Philips pressed steel pulleys, D.K. wood pulleys, etc. Representative: W. S. Hamilton.

J. L. Morrison Co., Toronto.—Full line of bookbinders' and paper machinery. Representative: W. Doldring.

The Massey-Harris Co., Toronto.—Portable saw outfits, gasoline engines in operation, 1 No. 15 self governing grinder driven by gasoline engine. Representatives: B. Graham, N. A. McIntosh, A. Verity.

Pratt & Whitney Co., of Canada, Ltd., Dundas, Ont.—Special exhibit of small tools for high explosive and shrapnel shells, full line of milling cutters, taps, dies, drills, and reamers. Representatives: T. R. Whitehead, A. Webb.

Preston Woodworking Machine Co., Preston, Ont. Tenoning machine, power feed saw, 12 in. molder, 36 in. band saw, 24 in. panel planer, 36 in. high speed ball bearing shaper and Newport attachment for molding machines. Representatives: W. J. Murray, W. E. Near, A. M. Kerr.

Tallman Brass & Metal Co., Hamilton, Ont. Arctic antifriction metal, brass and aluminum ware and castings.

Twin City Oil Co., Berlin, Ont. Feed crushers in operation. Manzel oil pumps, and compressors. Representative: A. V. Phillips.

Victor Saw Works, Hamilton, Ont. Power hack saws operating on shell material, Victor saw blades. Representatives: W. F. Pollock, A. V. Wilson.

A. R. Williams Machinery Co., Toronto.—Boyd boring machine for high explosive shells, Chapman transfer truck, Holden Morgan thread milling machines, 14 inch Le Blond engine lathe, Reeves wood pulleys, marine gasoline engines, rowboat motors, etc. Representatives: Messrs. Cronk, Kiechel and McDonald.

GENERAL SECTION.

The Canadian Fairbanks-Morse Co., Toronto, are exhibiting in the agricultural machinery section oil and gasoline engines for electric lighting, pumping and general purposes, also marine engines. A 25-barrel "Midget" mill is in operation. Representative, G. Wheeler.

The Dennis Wire & Iron Works Co., London, Ont., located in the Process Building, have an interesting line of "Dennisteel" clothes lockers, filing cabinets, safe cabinets and steel stools. Representative, M. B. MacNeely.

Consumers Gas Co., Toronto, have two exhibits in the Process Building, one being devoted to a display of gas-hardening furnaces for tool room, also forging and soft metal furnaces. "Tyco" and "Taylor" recording pyrometers are also to be seen. Representative, H. E. G. Watson.

The International Time Recording Co. of Canada, Ltd., Toronto, are demonstrating in the Process Building cost systems and time clocks. Representatives, F. Mutton, L. B. Morton, H. B. Lukens and J. F. MacBride.

The W. S. Mahaffy Co., Toronto, are exhibiting in the Grand Stand Section the "Lifton" transporting truck, also a number of warehouse and factory trucks of various types. Representative, F. G. Mahaffy.

CANADIAN NATIONAL EXHIBITION SHOWING SECTION OF THE GROUNDS AND LAKE FRONT.

The James Morrison Brass Mfg. Co., Toronto, are exhibiting in the Process Building a full line of brass steam goods, including safety and reducing valves, gauges, locomotive injectors and valves, etc. Representatives, A. Betton and W. Dobbin.

W. A. Drummond & Co. are showing in the Grand Stand Section an extensive line of dairy and refrigerating machinery and supplies, including a 2 ton and $\frac{1}{4}$-ton machine, the latter being in operation. Representative, A. P. MacDonald.

S. F. Bowser & Co., Inc., Toronto, have exhibits in the Transportation and Process Buildings. These include gasoline and lubricating oil systems, "Red Sentry" pump for automobile and curb filling stations. Representatives, R. W. Williams, H. T. Stern and A. E. Moffatt.

A. H. Wynter-Joiner, Ltd., Toronto, are showing in the Transportation Building a full line of the well-known "Weston" portable electrical instruments. Representative, S. E. File.

The Tygard Rotary Engine Co., Toronto, are demonstrating in the Agricultural Machinery Section the "Tygard" rotary engine. Two units, 22 h.p. and 30 h.p., are being shown. Representatives, Professor James W. Tygard and F. G. Moore.

WAR EFFECT ON MACHINE SHOP METHODS AND EQUIPMENT

IN the midst of numerous speculations as to the future of Canada's manufacturing industry, it may not be amiss to draw attention to the changed conditions under which in the coming time business problems will have to be approached and solved.

In a number of ways, the shell industry has been an eye-opener to us. Many firms which a year ago did but a limited business in machine work—iron founders, tinsmiths, structural workers and others, are now running a modern machine shop on most modern lines.

The requirements of a shop which must produce accurate work at a given figure, and also in a quantity, are understood more thoroughly now than ever before. Toolmakers are no longer frowned upon, the tool-room being recognized as something more than a mere luxury. The necessity for employing skilled help in maintaining output has been so borne in upon us that the application of scientific methods and labor-saving devices will be prosecuted with increased vigour when our manufacturing resources are again normally operated.

When such a time comes, there will doubtless be many who, having been fortunate in their selection of machines, will be able to adapt them to the more economical production of their various specialties. Plants which have installed automatic and semi-automatic machines, turret lathes, screw machines, etc., may be classed in this reckoning.

In competition with these, however, will be found others, and they may constitute a substantial majority, who, having a more varied assortment of equipment, evidenced their ingenuity in converting, adapting, and utilizing in numberless fearful and wonderful ways, anything that happened to be available. Regarding such, instances have come to light where machines by standard makers have been put to work on shell operations, the proper performance of which required, according to existent ideas, the utilization of complex machinery of ten times the value. Further, and as if to add insult to injury, the amount of tooling necessary was cut in half as a result of judicious experiment in methods and selection of materials, until the output of obscure machines became many times greater and was obtainable at a trifling cost.

When shells are a thing of the past, the activities of our plants will diverge and radiate in many directions. There will be a parting of the ways, and only balanced judgment will decide between success and failure—between a continued activity, rich in progress and development, and a helpless floundering in the mire of misdirected effort and inexperience. While naturally proud of our new, modern tool equipped plants, we must bear in mind that not a few other people have been using these same machines for years past, earning their living through them, and know just what they can do, and how much it costs to do it. Shell work may pay a fair return on the investment, but it offers no wide field of experience on different classes of work, either as regards materials or labor. The results obtained in shell manufacture indicate in moderate degree what may be accomplished in the direction of specialization of operations rather than of machines.

Specialization of equipment is exemplified by some recent productions in the United States where machines of the multiple type have been developed to a marked degree. The use of such machines, or even a tendency in that direction can, however, be justified only by a demand which would keep a sufficient number of them busy, and warrant the employment of the expert help necessary for maintaining their operation reliability and up-keep expense.

Our Manufacturers' Honor Roll

Representative of Canadian manufacturers, their families and administrative staffs who have heeded the call of Empire for active service on our various overseas contingents.

LIEUT. W. S. DREWRY,
E. L. Drewry, Ltd., Winnipeg.

MUNITIONS WORKER AND SOLDIER

SPEAKING recently at a meeting of emp loyees of Swan, Hunter & Wigham Richardson, Wallsend-on-Tyne, Dr. Hunter challenged the accuracy of the oft-repeated assertion that men in the factory were as useful as those at the front, and declared: "It is not true. A man at the front is twice as good as a man in the factory. These men are making sacrifices, and it will be a shame and a crime if, through any slackness on our part, even one of these brave lives is lost."

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., Aug. 30, 1915.—There is a firmer tone in the metal market, due to the fact that the demand is increasing without definite assurances of increased supplies. A general increase of $1 a ton is announced on pig iron and an increase of $1 a hundred on spelter. The demand for pig iron is fairly quiet, there being supplies available for all requirements.

High Speed Steel.

The high speed steel situation has reached a point that is looked upon by many as serious. It is becoming daily more difficult for dealers to fill orders, although some firms are fortunate in having a fairly large stock on hand. The representatives of one British firm are feeling very optimistic over the fact that they have a shipment on the ocean which will be due here shortly, but in this respect they seem to be entirely alone. It is freely prophesied that owing to the embargo against shipping steel from the Old Country containing tungsten or molybdenum the high speed steel situation here will become more and more acute, and two dollars a pound steel is looked for at a quite early date. In some cases larger-sized bars and unusual sizes have been re-rolled, but the amount of this additional supply of stock will not affect the situation to any extent. It would be wise for manufacturers to look into the future a little as far as their stock of high speed steel is concerned, and assure themselves that they will not have to suspend operations owing to the possible inability of securing a suitable supply.

A notable feature at present is that antimony which has been quoted around 40 cents has been steadily declining. There is little British antimony on the market, but recently it has become apparent that it is possible to secure fairly large quantities of Chinese and Japanese material. While 30 cents has been the figure quoted in the United States, this is even shaded at present by Montreal dealers. Another factor is also apparently affecting the situation, it being rumored that shrapnel bullets will be made in the near future without the use of antimony. A gentleman in close connection with the Government informed your representative that shrapnel bullets which were being tested by the Government were apparently giving most satisfactory results, and if these are adopted, the use of antimony will be eliminated from the manufacture of shrapnel shells altogether. This will have a tendency to depress the market still further. British antimony is scarce at 40 cents a pound, and Chinese and Japanese is quoted at from 27 to 29 cents.

Machine Tools and Supplies.

A striking indication of the scarcity of machine tools is illustrated by the fact that a Montreal firm have a large order for Canadian-made machine tools from Great Britain. Although they have made a special effort to fill it, so far they have been unable to get any quotations representing what would be considered a reasonable time for delivery. As far as the Montreal market is concerned, Canadian-made machine tools, except an occasional second-hand unit, are not to be had, and it is apparent that this condition will continue for some months to come. Some Montreal dealers are well supplied with second-hand tools, and a fair amount of new American machines; for these a good demand is reported.

Leather belting manufacturers report that the great scarcity of raw material has made it next to impossible to secure enough leather to enable them to fill orders. At the beginning of the war the saddlery manufacturers and boot and shoe dealers secured practically all the available stock, and in some instances were helped out by the leather belting manufacturers, who could now use large quantities to advantage, but are unable to secure same. There is demand for all kinds of small belting in connection with the manufacture of war munitions; in fact, this market is extremely active. The demand for small-sized belts is greater in Montreal than it has been for a great many years, and there seems no sign of a diminished activity along this line.

ALLIES' PURCHASING AGENTS.

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:—

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendance Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Attache, Russian Embassy, Washington, D.C.

Toronto, Ont., Aug. 31.—It is generally believed that the British Government will continue to place orders for war equipment in Canada while the need lasts. The prospects for further improvement in business are therefore bright, more particularly with regard to the export trade. The indications point, especially in the West, to a heavy crop, which will have an exceedingly beneficial effect on business generally. There have been no developments of importance in the shell industry recently, but there appears to be little doubt that further orders will be placed, particularly for high explosive shells as soon as Canadian plants are in a position to turn out fixed ammunition. It is understood that David A. Thomas, the representative of the British Government, is favorably impressed with what he has seen during his investigations as to what can be done in Canada towards making shells.

With regard to domestic trade, conditions generally speaking are quiet, but considerably better than earlier in the year. The large increase in the export trade will no doubt in time have a stimulating effect in the domestic business. There has lately been a more active demand for agricultural implements and consequently a few iron foundries have been doing better business; the majority of plants, however, are feeling the effects of the depression. The building trade locally has picked up a little, but is still considerably below normal. Municipal work all over Canada has been very light this season on account of the difficulty in financing improvements.

Steel Market.

Conditions in the steel trade continue favorable, due to the increase in the export business and the large demand for bars and forgings for shells. The recent orders for railway cars have also created a demand for steel. It is announced that the Nova Seotia Steel & Coal Co. are working day and night on shell orders and are also making a large number of forgings for Clyde shipbuilders. Prices on all steel products are holding very firm although there are no changes to note this week.

The recent strength in the spelter market has had an unsettling effect on the sheet market, and prices are irregular. Following the decline in the spelter market, prices of sheets weakened, but are

now firmer, and some mills are refusing to quote for contract delivery because of the uncertainty of the price for spelter.

The high-speed tool steel situation shows no improvement and prices for the finer grades of tool steel have advanced again due to the increasing cost of tungsten and scarcity of supplies.

Conditions in the steel trade in the States continue very active. The heavy demand for steel rounds for shells is the leading feature, and specifications are coming in so fast that the mills are getting further behind on deliveries, notwithstanding the heavy shipments. Prices on bars and shapes are firmer, and some business is being done at 1.35c Pittsburgh.

Pig Iron.

Pig iron prices in the States have advanced in all markets, grey forge being now quoted at $14.45 Pittsburgh. The situation locally has not changed materially and the demand for foundry iron is light. Hamilton and Victoria brands are unchanged at $19.

Scrap Metals.

Prices on various scrap metals are unchanged with the exception of heavy melting steel, which has declined and is now quoted at $7; this is accounted for by an excess of supply over demand. Copper and brass scrap are in good demand and the market is firm.

Machine Tools.

There is no change in the situation, the demand for new tools is less active, but deliveries are no better. Prospective shell manufacturers are in many cases keeping out of the market until more orders for shells are distributed. Some firms already engaged in producing shells are buying tools from time to time to readjust their plants, or for extensions. There is a good demand for second-hand tools, and deliveries are better on this class of equipment, especially for lathes.

Supplies.

A brisk demand for small tools such as cutters, dies, taps, etc., is reported, and good business is being done in almost all lines of machine shop supplies. An advance in the prices of waste has been made, varying from ¼c to ¾c per pound. The new prices are given in the selected market quotations. The increased cost of raw stock is the reason for higher prices.

Metals.

The feature of the market this week is the recovery of spelter following heavy buying. Although there is a good demand, indications point to an attempt by sellers to advance the market. The tin market is unsettled with a weak tendency. The copper market is unsettled, and prices are slightly higher. Lead is stronger and aluminum are quiet and firm at unchanged quotations. There is a good demand for metal for munitions, but ordinary business is only moderate.

Tin.—The New York market is dull and unsettled with a weak tendency. This dullness is caused by the failure of the London market to advance in this metal in proportion to copper and spelter. Local quotations are unchanged at 19c per pound.

Copper.—The market is unsettled and the situation uncertain owing to prices being advanced for no apparent reason. Copper consumers have been out of the market for some time and a buying movement may follow as a result. The market has advanced ½c locally, and lake copper is being quoted at 19c per pound.

Spelter.—The market has re-acted and prices are higher, some large orders having been placed in New York for prompt and early delivery. The market is excited and indications point to manipulation. The advance is 3c locally at a nominal quotation of 19c per pound.

Lead.—The market is more active and lighter. The Trust has advanced their price to 4.90c New York. Locally lead has advanced ¼c and is quoted at 6¼c per pound.

Antimony.—The market is quiet but firm for future, and unsettled for spot delivery. Quotations are unchanged at 40c per pound.

Aluminum.—The market is quiet but firm and unchanged at 40c per pound.

CANADIAN GOVERNMENT PURCHASING COMMISSION.

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George Gault, Winnipeg; Henry Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

OCEAN TONNAGE SHORTAGE.

IT is said that an agreement has been reached between the Governments of Great Britain and Canada whereby the former will recognize the urgency of the situation and refrain as much as possible from commandeering ships that are needed for grain. So far as the ocean tonnage is concerned, however, the shortage is by no means so serious as has been claimed in some quarters; but while the passenger service has in some cases vanished, and in general has been reduced to a minimum, there has sprung up in its place a freight service that far surpasses any that Canada has owned in the past. The big liners have been replaced by large freighters.

Investigation has shown that at the present time the Cunard Company has four of these vessels, two of which have already visited the port of Montreal, although under changed names. This fact is also testified to by officials of Lloyds. In this way the absent passenger boats have to a considerable extent been replaced. That the available tonnage to carry grain will compare not altogether unfavorably with past years is illustrated by the fact that while the Victorian, one of the largest of the passenger boats (an Allan liner) could carry only about 4,000 tons of grain, the Monarch (one of the freighters replacing passenger ships) can accommodate between 8,000 and 9,000 tons. So, while the number of ships may be less, the carrying capacity will be much greater than has generally been believed.

MACHINE TOOL OPENING IN RUSSIA.

THE Department of Trade and Commerce, Ottawa is in receipt of a communication from the office of the High Commissioner for Canada at London, enclosing the name of an English firm, with connections in a number of the important centres of Europe, who desire to get into touch with a reliable Canadian merchant firm or manufacturing house to act as purchasing agents for machine tools and other plants. The firm in question has recently sold some machine tools to Russia for the manufacture of ammunition and have received additional inquiries for shell-making plant, but on account of the taking over of the English tool-makers by the English Government, it is not possible at present to offer English-made machines for some types of shells.

This English firm therefore would like to communicate with one large manufacturing house in Canada, which could supply the major part of the plant itself and get tenders for the remaining part, or else with a merchant house in Canada, who are thoroughly acquainted with the machine tool business and who could give them tenders for plant, getting the machines from the various manufacturers, with whom they are acquainted. Canadian firms, who may be interested in supplying the equipment that is asked for, will obtain the name and address of the firm in question, who are making the inquiry on behalf of their Russian clients, by applying to the Department of Trade and Commerce, Ottawa.

S. S. "ONTARIO NO. 2" TRIAL TRIP.

CAR ferry Ontario No. 2, which will ply between Cobourg and Port Charlotte in connection with the Grand Trunk Railway, made her initial trip, the builders' trial, on Saturday, Aug. 28, with about 200 guests aboard. The behavior of the new vessel was most satisfactory in every respect. The Ontario No. 2 was built and engined in Toronto at the yards of the Polson Iron Works, Ltd.

The new ferry is 318 feet long; beam moulded 54 feet; depth to main deck, 20 ft. 6 in.; draft loaded, 16 ft. 3 in.; tonnage, 5,400; horse-power, 4,500. She has two propellers, each driven by a jet condensing triple-expansion engine having cylinders 20½ in., 30 in. and 54 in. by 36-in. stroke, and making 110 r.p.m. The boilers are Scotch type, four in number, each being 14 ft. diameter by 12 ft. long, and giving a working pressure of 180 lbs. per sq. in.

Captain F. D. Forrest, Commodore of the Ontario Car Company's fleet, was at the helm, and W. H. Smith, manager of the company, represented Vice-President Kelly of Chicago, who was unable to be present. The new ferry will go into commission on October 1, taking the place of the car ferry Ontario No. 1, which will be laid up for the winter.

The new vessel has accommodation for thirty cars, each carrying seventy tons, also accommodation for one thousand passengers. The guests were entertained to a buffet luncheon. A Boy Scouts' pipe band provided music as the visitors inspected the various sections of the new vessel. Upon the return of the ferry to her moorings at the Polson Iron Works, Ltd., yards, a vote of thanks was tendered Col. J. B. Miller, president and general manager of the latter company.

Guests.

Among those on board, which included a large number of ladies, were: Col. J. B. Miller, W. H. Smith, J. W. Griemer, fleet engineer of the Ontario Car Ferry Co., and W. F. Crawford, the chief steward; Captain Harry Polson; William Newman, naval architect and works manager of the Polson Company, who superintended the construction of the new vessel; A. H. Jeffrey, A. E. Matthews, Captain W. J. Bassett, J. T. Mathews, Captain M. Corcoran, Mayor Church, Alderman Ramsden, Alderman Ryding, J. W. Somers, George Stevenson, Captain Evans, John Dodds; H. E. Wittenberg, General Superintendent, G. T. R.; W. H. Farrell, Superintendent of G. T. R. Terminals; E. C. Horning, District Passenger Agent, G. T. R.; Edmund Bristol, M.P.; W. C. Seeley, Master Mechanic of the Middle Division, G. T. R.; J. R. Leckie, Assistant Master Mechanic, G. T. R.; W. S. Wilson, Superintendent of Transportation, G. T. R.; W. Hamilton, L. Grabbel, Assistant General Baggage Agent, G. T. R.; J. D. O'Connor, J. W. McClintock, James Stewart, ex-Alderman James McCausland, Frank Ryding, Jack Edmunds, A. G. Webster, "Marine Engineering of Canada," etc.

Production of Shells in a Plant Specializing in Cut Gears

Staff Article

Resourcefulness in gripping and mastering the details of shrapnel shell manufacture has not, as will have been noticed from our leading articles in this and recent issues, been confined to any particular section of Canadian mechanical engineering enterprise. The plant here featured, although not a leader in point of size, earns that distinction in its output.

PREVIOUS to taking up the manufacture of shells, the plant described in this article had been devoted exclusively to the production of cut gears. While the gear-cutting machines themselves were of no use in shrapnel work, the larger part of the shop equipment fitted in very closely with the new requirements. Considerable additional machinery was installed, but it was almost all of the same kind as that already in use, and merely represented such extensions as an ambitious factory manager might hope to add to such a plant during the next two or three years. The hardening room, which department has given so many shell makers a full measure of trouble, did not in this case require any changes except the addition of a larger soda water boiler and a larger quenching tank with circulating coils for cooling water.

The organization of this plant is based on a production of one completed shell every three minutes. The exact sequence of operations on 18-pounder shrapnel varies somewhat according to available facilities, but in a broad sense the general grouping of operations is similar in most plants.

The preponderance of Jones & Lamson flat turret lathes in this shop will be noted, as well as the fact that a number of these are of the double spindle variety, finishing two shells at each revolution of the turret.

Referring to operation 1—cutting off—the machine in which this is done was designed and built by the Hamilton Gear & Machine Co., Toronto, and has been in demand from other shops since the shell business began to assume its present importance. The shell is encircled by an annular chuck with automatic jaws, which grip the shell body and leave both ends exposed. The shell is located by a stop rod, positioning from the inside of the base of the shell. Excess metal on the base of the forging is removed by one tool, while the open end is trimmed to the correct length by a cutting off tool. These tools are located on two separate slides, one on each side of the chuck, with different rates of feed (ratio about four to one) to suit their work. They thus automatically size the overall dimensions of the forgings. Owing to the great variation in the thickness of the bases of the rough forgings, it is sometimes necessary to take a very heavy cut, as much as five-eighths of an inch having been encountered. As indicated by the illustration, Fig. 1, ample belt power has been provided for this heavy work.

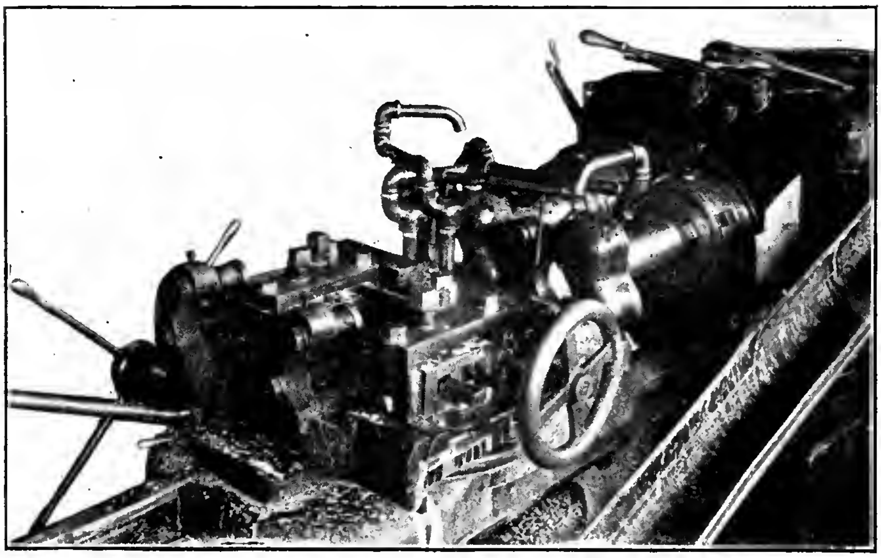

FIG. 2. DOUBLE SPINDLE LATHES EQUIPPED WITH UNIT TOOL BLOCKS.

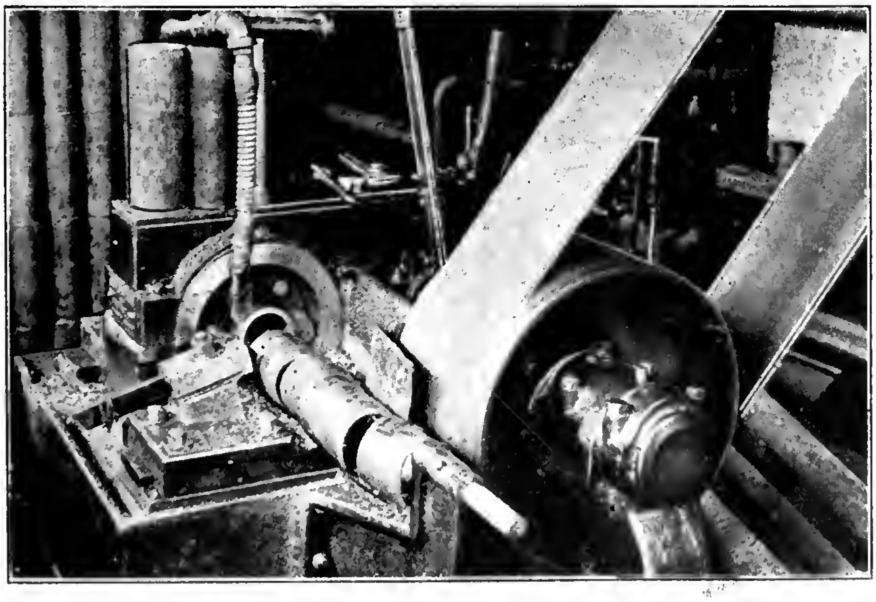

FIG. 1. "HAMILTON" CUTTING-OFF MACHINE.

Operation 2 includes rough turning the outside, finish face base, round off corner and machining groove. It is handled on two double spindle and one single spindle J. & L. flat turret lathes, size 3 in. x 36 in. The tool arrangement on these machines is decidedly interesting. That supplied by the machine builders was found capable of improvement, and a complete revision of the equipment resulted, as shown in Figs. 2 and 3.

The work of waving and undercutting the band groove has been concentrated on one single spindle machine, and the balance of the operations left to the other three machines of the battery, as mentioned above.

Unique Tooling

The gang tooling and the interchangeable unit tool blocks used on these machines are particularly interesting points, and are shown in Fig. 3. The three separate tools for finishing base,

rounding corner, and machining groove are shown in place, while on the right of the illustration the block is dismantled, showing separate rocking plates under each tool. These cutting tools are all maintained at standard angles and dimensions, and are kept in the tool room along with the tool-setting jig shown in the illustration. This jig is so constructed as to hold the tool block in the same relation to a dummy shell A (which is part of the jig), as it will bear to the work on the lathe. Spare blocks with the tools already set up are kept in the tool room ready for the lathe hands.

FIG. 3. UNIT TOOL BLOCK, ASSEMBLING JIG, AND COMPONENT PARTS.

The fixture used for cutting the dovetail in the band groove is rather unusual. It is shown in Fig. 4, from which it will be noted that both tools work from the same side and operate simultaneously. The shape of the tool holders is such that straight bars of square ready-hardened high-speed steel can be used, being ground only on the front end. The cutting edges are well supported, and the tools cheap and of such size that they readily conduct the heat away from the cut. It is, therefore, possible to work dry.

There is nothing very unusual about the boring operation except that it is split betwen two machines. The roughing is done on a 25-in. "Gisholt" big bore turret lathe, and the finishing on a double spindle Jones & Lamson machine, Fig. 5. The shells at this point are ready for the furnace room.

Coal Fired Furnace

The heat treatment is a particular feature of shrapnel manufacture, and the principles involved have been frequently discussed. As mentioned above, the equipment used is the same practically without alteration as that used for heat-treating and case-hardening

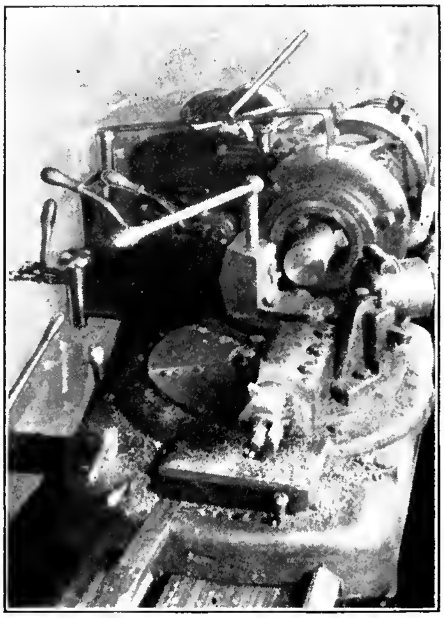

FIG. 4. UNDERCUTTING BAND GROOVE ON J. AND L. FLAT TURRET LATHE.

gears. In heating the shells for hardening, a large Brown & Sharpe oven furnace is used, and the fact that anthracite is the fuel renders this operation worthy of note. This is especially so in view of there being no sealing from the exposure to the direct heat of the fire. There are reasons for this.

First, the heavy bed of incandescent fuel, with only a moderate blast, maintains a reducing atmosphere in the furnace. Second, the base and band groove of the shell are painted before insertion in the furnace with a mixture of boracic acid and animal charcoal (bone black), mixed to a creamy consistency with quenching oil. Any slight amount of oxygen in the furnace would, therefore, have to consume the carbon before attacking the steel, and the boracic acid makes the cleaning of the surface with a rotary wire brush quite easy. No sand blast is used.

The shells are quenched at a suitable temperature in a tank of soluble quenching oil, a copious stream of oil being introduced inside the shell at the same time. Subsequent tempering to a suitable scleroscope reading brings the strength of the shell to the desired degree. The only subsequent cleaning required consists in washing in boiling soda water, rinsing off in clean water, and brushing with an "Economy" wire brush on buffing stand.

In the next operation, the nose of the shell is heated in a lead pot (gas fired) for about two inches, and crimped to shape in a hydraulic press. The shell is then reheated in the same furnace to relieve strains in the steel and afterwards placed muzzle downwards in a tray of ground mica to anneal.

The succeeding operation is done on two single spindle flat turret lathes, Fig. 6. This operation consists in trimming the shell to exact length, boring the nose, forming the inside curve, tapping the nose with a "Geometric" collapsible tap, and rough forming the outside curve of the nose. Both inside and outside curves are formed with flat cutters, brought into operation by cross traversing the head of the machine. All the operations on flat turret lathes are controlled by stops, both for length and diameter movements.

Noiseless Grinding

Finishing of the parallel portion of the body on a "Ford-Smith" grinder constitutes the next operation. The nose profile is not ground. The holding arrangement used on this machine is somewhat different from that in other shops, in that the shell is mounted on centres, using a cup over the base, and is driven by gripping the nose end on the rough shell about where the shoulder is to be finished. (See Fig. 7.) This method of driving relieves the chuck of all strain due to the pressure of the grinding wheel. The live centre offers a much firmer support for the shell, and conveys

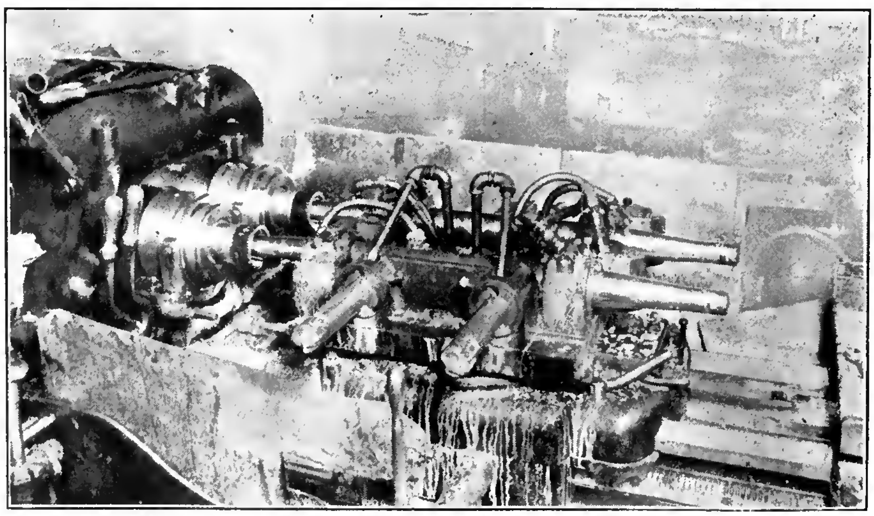

FIG. 5. BORING EQUIPMENT ON DOUBLE SPINDLE J. AND L. FLAT TURRET LATHE.

the grinding vibration directly into the frame of the machine, where it is absorbed. The reduction of noise due to this arrangement is remarkable, the shrill whistle, which is so objectionable when using a chuck, being almost eliminated.

The shells are then passed on, with the plug centres still screwed into the muzzle end, to the engine lathes (two in number), which finish the balance of the profile.

The profiling attachment used varies somewhat from the usual arrangement. The templet, Fig. 8, is mounted on a rigid bar, which is securely fastened to the tailstock instead of the headstock, as in some cases, or the lathe bed in others. The adoption of this principle overcomes the necessity for locating the shell accurately in the chuck in relation to the templet, and also enables full advantage to be taken of the allowable variation in the overall length of the shell, so that when a shell comes through which is a little long, it is not necessary to remove any more metal than is necessary to come below the high limit; whereas when the profile copy is fixed rigidly to headstock or lathe bed, the tool will cut to the same point every time, unless the shell be adjusted in the chuck, which takes time, and is not so easily controlled as the method described.

Unusual Profile Attachment

In the present case the shell is chucked without any unusual care, and the tailstock centre brought up to position. This is done by sliding the tailstock a trifle nearer the shell than necessary. The shell, previously trimmed to size on the end, and being now fitted with a centre plug, the machined surface on the end of the shell is used as a point from which to gauge the position of the tailstock, a suitably prepared point on the end of the tailstock casting being used. As the profile copy is rigidly fastened to the tailstock casting, its position in relation to the nose of the shell is determined accurately and individually for each shell.

After a thorough cleaning, the shells are carefully gone over by a shop inspector and submitted to the Government inspectors for the preliminary inspection of the completed steel shell case. On leaving the Government inspection room, the shells travel in a circular path from one machine or bench position to another around three sides of the loading room without any halt or backward motions. By this means a great saving is effected in the handling and in storage space. The first operation in the loading room is the pressing on of the copper driving bands, which is performed in the conventional manner, using a six-cylinder hydraulic press of the tire-setting type. From this machine the bands pass to a 3-in. x 36-in. Jones & Lamson flat turret lathe, where the bands are turned. Two forming tools, a roughing and finishing, are used, the former feeding radially and the latter being drawn through under the work in a direction tangent to the surface.

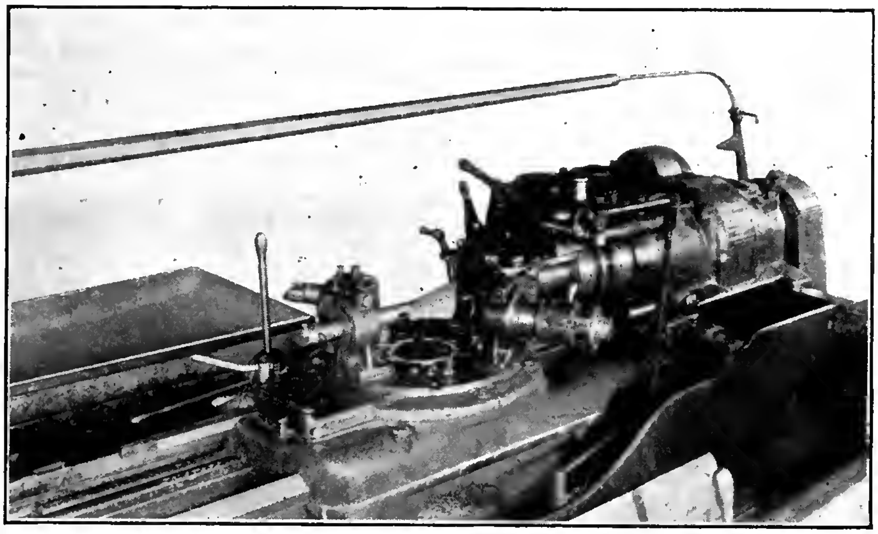

FIG. 6. MACHINING AND THREADING NOSE OF 18-PR. SHRAPNEL SHELL.

Assembling

The copper band inspector picks up the work from the tray on the rear of the lathe and, after examining the band, lays the shell on the assembling bench close by the man who puts in the tin powder cup and brass firing tube. This cuts out two handlings. The shell is then filled with lead bullets and the total weight checked. The remaining space is then filled with melted rosin, which, on cooling, acts as a matrix and prevents any loosening of the internal parts under the shock of being fired from the gun. An additional object of the rosin is to generate a cloud of smoke when the shell is exploded so that the accuracy of aim and range may be observed and controlled by noting the smoke clouds.

The weight of the shell, including the rosin, is again accurately checked, and the brass socket is screwed home in the threaded nose. The end of the firing tube projects through the central hole in the socket and the joint between these two is now securely soldered. An electric soldering bolt with hollow point is used for this operation. The shell is now ready for the last machine operation.

A Simple Lathe

The outside form of the socket is turned and the excess solder removed from the inside in a special lathe built by the Hamilton Gear and Machine Co. for the purpose. It is purely a single operation machine, being a lathe reduced to its lowest terms. It consists of a heavy spindle mounted in two generous

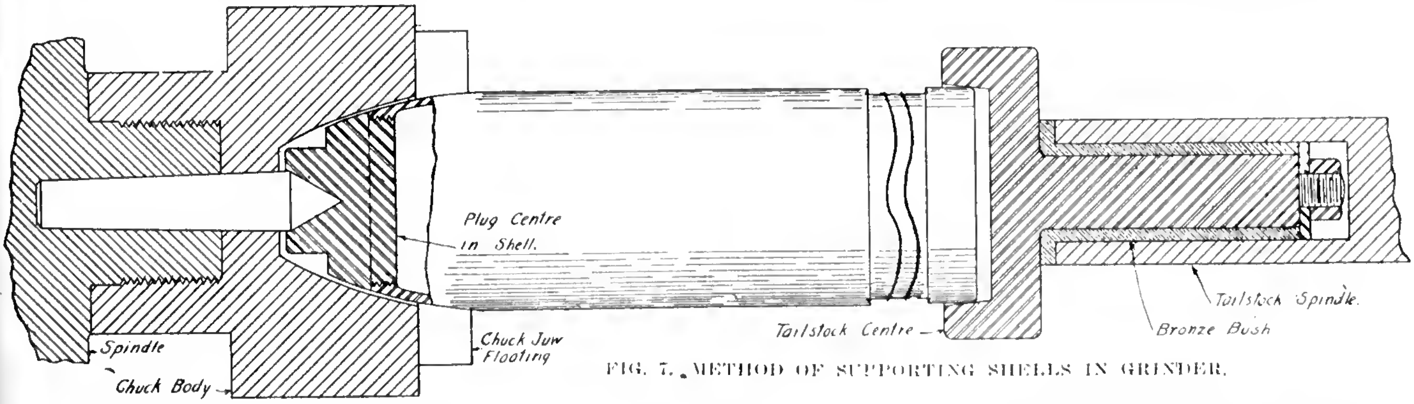

FIG. 7. METHOD OF SUPPORTING SHELLS IN GRINDER.

ring-oiling bearings and driven by tight and loose pulleys and a wide belt. The shell is mounted in a simple chuck of the hinged type, which grasps it back of the shoulder. Fig. 9 shows a plan of the tool carriage in which three tools are used—front forming tool for the curve of the profile, back forming tool for the recess or check, and a boring or facing tool for trimming the inside of the socket and removing the excess solder. The hand wheel on the cross-feed screw is large, being about 9 in. diameter, and graduated on the rim to read in thousandths of an inch. Easy reading and rapid work are facilitated by the large circle and wide graduations. Of course, simplicity of the tooling is also a factor in the quick production which is obtained with this equipment.

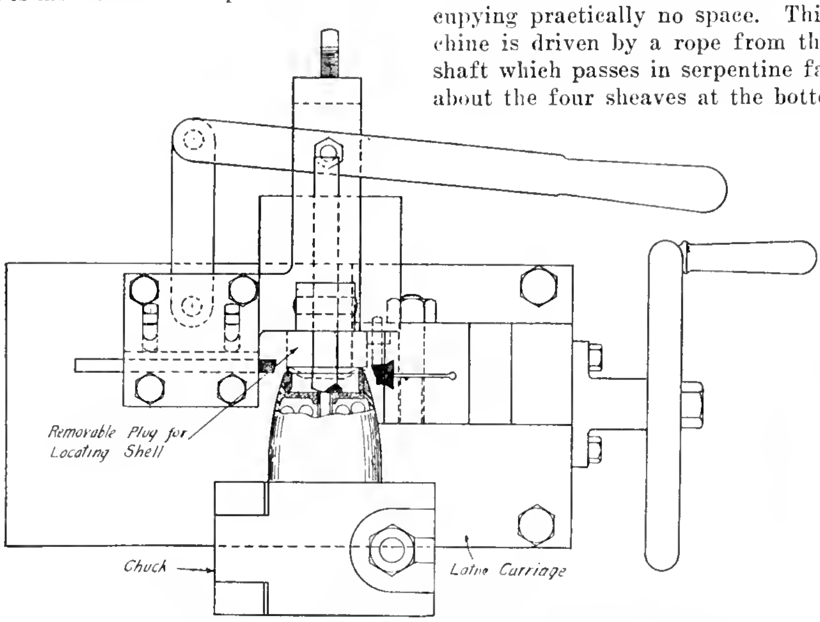

FIG. 9. PLAN OF TOOL CARRIAGE ON SOCKET TURNING LATHE.

Flat Die Marking Machine

The sockets are next hand-tapped with an expanding adjustable tap, which is kept in accurate agreement with the Government gauges, then passed to an inspector and afterwards to the marking machine. The latter handles the shell in the usual oscillating manner, supporting it on rollers, but differs from the usual type, in having the letters in a flat die holder, which is traversed back and forward under pressure by a rack and gear segment. This form of construction has a number of advantages, chief of which is the cheapness of type and the readiness with which they can be changed when single letters become damaged or worn out.

After marking, the shells are carefully blown out with compressed air and again checked for weight before passing to the Government inspector for the final inspection and marking with the official acceptance stamp.

The last operation is the painting, which is done on a four-spindle machine let into a slot in the bench top and occupying practically no space. This machine is driven by a rope from the line shaft which passes in serpentine fashion about the four sheaves at the bottom of the spindles. After painting, plugs are screwed into the sockets to protect them from damage in shipping, and the shells are packed in the regular six-round boxes supplied by the Government.

The main feature of this plant, aside from some very ingenious examples of tooling, is the demonstration of how much can be done with very limited floor space in the way of eliminating storage intervals and handling between operations. The machines are set very close, and at each operation where possible the shifting from one machine to another is done by an inspector, who picks up the work from the previous machine and, after examination, places it ready for the next operator. In many cases he can do this without taking more than one step. On some operations, galvanized iron chutes are used to carry the shells between inspectors' and operators' positions.

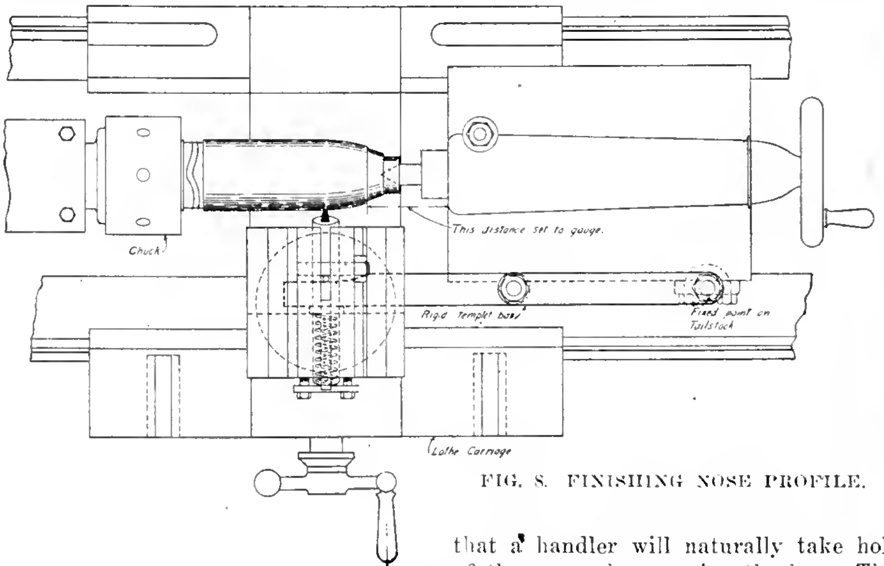

FIG. 8. FINISHING NOSE PROFILE.

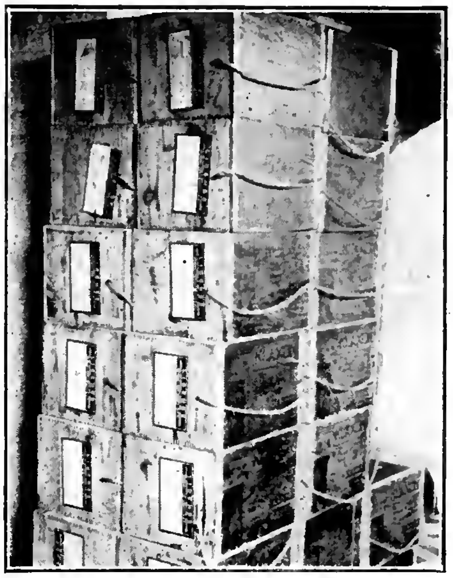
A SHIPPING KINK.

By A. E. G.

THE Lovell-McConnell Mfg. Co., Newark, N. J., makers of Klaxon automobile signal horns, had considerable difficulty in packing the latter so that the bell of the horn would not be dented in transit. The trouble was principally caused by the handlers dropping the box in which the horn was packed with more or less force, and if the bell of the horn happened to be



A SHIPPING KINK.

downward, the result was almost sure to be a dented or crushed bell.

Someone in the shipping department finally hit on the plan of putting rope handles on all the shipping boxes, so that a handler will naturally take hold of the rope when moving the box. This keeps the boxes top up in almost every instance, and as the horns are packed accordingly, the result has been very satisfactory.

PRODUCTION METHODS AND DEVICES

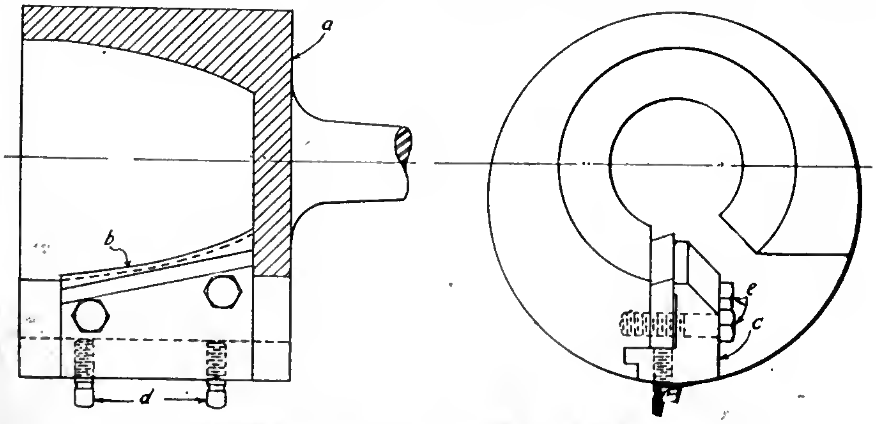
A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

HOLLOW PROFILE MILL FOR SHELL NOSES.

A SIMPLE design of hollow mill with single inserted cutter for finishing the nose profile of 3.3-inch H.E. shells is shown in Fig. 1. The cast iron body (a) is provided with a suitable taper shank to fit drill spindle, and is bored out, as shown, to fit the finished shape of the shell. This hole is concentric with the shank, but the outside diameter of the mill is made considerably eccentric. In the end view it will be observed that this heavy side is partly cut away to allow of the blade (b) being secured in the proper position. Clamping plate (c) is formed with a heel which fits into check shown, and provides suitable support for the adjusting screws (d) which are used in setting the blade (b).

Clamping screws (e) pass through clearance holes in the plate, and into tapped holes in the body (a). Blade (b) has two oval holes with ample clearance, so as to allow of considerable wear on the cutter being taken up without fouling screws (e).

Suitable clearance space for chips, etc., is provided by this design. This tool is used only for the finishing cut or scrape, and enables the desired profile to be obtained easily by means of adjusting screws (d).



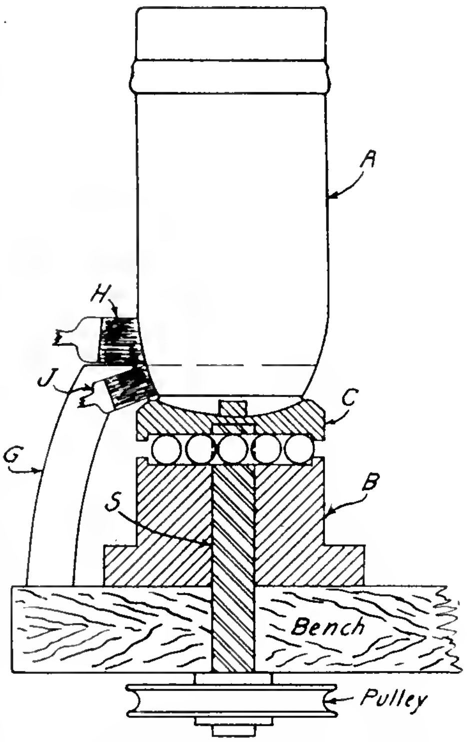
FINISHING CUTTER FOR SHELL NOSE.

BALL-BEARING SHELL PAINTING DEVICE

By J. H. R.

SHELL manufacturers throughout the Dominion are employing several different methods for painting shells. The device here shown is used in one of our smaller plants, and while the output is somewhat less than with other painting machines, it meets the requirements of the shop production.

The cast iron base B which is secured to the bench, has a ball-race of suitable size machined on the top. Through the centre of base B a hole is drilled to fit



BALL-BEARING PAINTING DEVICE.

the shaft S, the latter being fastened into the head C which is also made of cast iron. A ball-race of the same dimensions as that in the base is machined on the bottom of C and on the top is formed a cup-shaped recess with a square pin projecting upwards to engage the square hole of the plug in the shell nose. Several balls of a suitable standard size are placed in the ball-race, and the head C is placed in the position as shown in the drawing. The operation is as follows:

The shell is placed in the head C, the latter being revolved slowly by means of a small grooved pulley placed on the shaft S, beneath the bench. In painting, the brush H is held against the revolving shell and is moved along the body as far as the limit set by the gauge G. This gauge is of the correct height and is fastened to the bench. Above this gauge the shell is painted dull grey and below by means of the smaller brush, J, the nose of the shell is colored red also to the required distance.

SUGGESTION FOR CUTTING SPIRALS.

By G. Miller.

THE following rule or idea may not be new; in fact, may be known to a large number of mechanics, for, as a certain wise man once said, "there is nothing new under the sun," yet as the writer has never seen it mentioned in any mechanical paper, and as it may be of assistance to some worried mechanic and help him out of a "hole" some time, its uses and advantages are here set forth.

The printed tables accompanying universal milling machines do not give all possible combinations of gears for cutting spirals, and to "figure out" the right gears to cut a special spiral for which the printed table does not make provision, requires, in some cases, a considerable amount of mathematical knowledge. Suppose we wish to cut a groove in a one inch piece—a one inch twist drill blank for example,—so that this groove makes one complete turn around the piece in a length of six inches. If we were able to unroll this piece into a flat surface, we would have a rectangular piece of 6in. long by 3. 1416 in. wide with a groove diagonally across its face from one corner to the other as shown by Fig. 1, or if we wish to cut a spiral 1 in. in diameter, the groove to have one complete turn in 3 in., its unrolled surface would be represented by a rectangle 3 in. by 3. 1416 in. with a groove diagonally across its face from corner to corner as shown by Fig. 2.

From this it can be easily seen that to cut any spiral it is only necessary to know the diameter of the piece and the lead of the spiral, that is the length of piece required for the groove to make one complete circle around it. From these dimensions a rectangle can be easily drawn. The difference in the length of the base line and the upright line is the ratio between the turning gears and the feeding gears. If the

piece to be cut has a circumference of 4 in. and the groove is to make one complete turn in 2 in. this would be represented by an angle with a base line of 4 in. and an upright line of 2 in., which would show that the revolution of the piece to be machined would be double the speed of the feed of the machine, the base line in all cases representing the revolution of the blank and the upright line representing the feed.

The writer is reminded in this connection of a certain case where some thousands of spirals were to be cut in a cer-

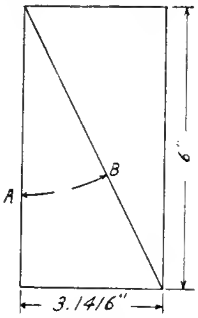


FIG. 1.

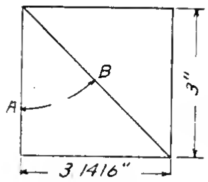

FIG. 2.

tain shop on one of the best makes of American milling machines. In this particular instance the printed rules accompanying the milling machine had to be cast aside as utterly useless and the rule herein given was successfully applied. There is another application of this rule that the writer has found useful.

It may not be generally known that the printed tables accompanying universal milling machines do not always and in all cases give the correct number of degrees and minutes to set over the table when cutting spirals. This statement will probably be discredited by some people, especially makers of milling machines, but the writer knows it to be true, not only by years of observation, but by actual experience.

All mechanics when cutting spirals know that if the "set over" of the table of a milling machine is not parallel with the proposed groove in the blank, the cutter will "drag" more or less on one side or the other, and raise a burr that is detrimental to good work. The writer has seen burrs raised on spirals by a too faithful adherence to the printed tables that would set one's teeth on edge, mechanically speaking. By use of the rule given in the first part of this article and a very slight knowledge of trigonometry, the correct position for the milling machine table can be quickly found. All that is necessary being to know what angle it is from A to B, Fig. 1 or 2, the unrolled diagram of the proposed spiral being the correct angle to set over the table. By making a very careful diagram of the angle and using a good bevel protractor a very close approximation to correct measurements can be found. It may be objected that it is not necessary to go to all this trouble as the correct angle for the table may be found by marking across the blank with the milling cutter and then using a straight edge, but this method can be used only with spirals of very little lead, and only in some cases, and can never be used with any assurance of success when cutting spiral gears with larger lead.

OIL-GROOVING ON A PLANER

By A. E. Granville.

MANY firms building machine tools still chisel out the oil grooves in their machine beds and tables by hand, using a round-nosed gouging chisel. This is a slow process and, as a rule, looks amateurish, except on machines that are too large to have the work done in any other way. The oil-grooving of gibs or other small pieces by hand, however, has little excuse where the parts are used in any reasonable quantity, as there are numerous ways of doing the work quickly and cheaply on a planer.

A planer rigged up for grooving gibs is shown in Fig. 1. Here the gib is placed in a holder, which is bolted to the planer table. The gib is butted against one end of the holder, and is held in place by two set screws and clamping pieces A and B. The oil groove cut is plainly shown at C. In placing the attachment on the planer, the cross-fed screw is loosened so that the saddle will move freely on the cross-rail. The bracket D is then clamped to the rail as shown. This bracket carries the bell-

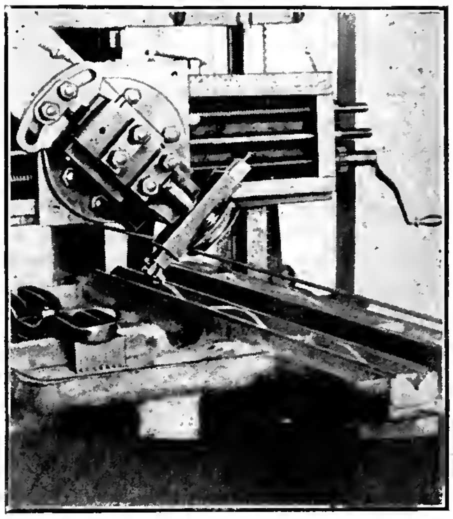

FIG. 3. HEAD SET FOR BEVEL WORK.

crank E, which is connected to the saddle by the link F, while a connecting rod G connects the other arm of the bell-crank to the crank disc H.

A ball-and-socket joint is used at each end of the rod G in order to allow for the movement as the mechanism operates. The crank-disc is geared to the main driving shaft, so that the saddle is given a rather slow reciprocating movement, as the planer table travels beneath it. The amount of stroke can be varied considerably by adjusting the end of the rod G in the slot of the crank-disc, and also by sliding the bell-crank up or down in the slot of the bracket. The gearing may also be changed when needed. When

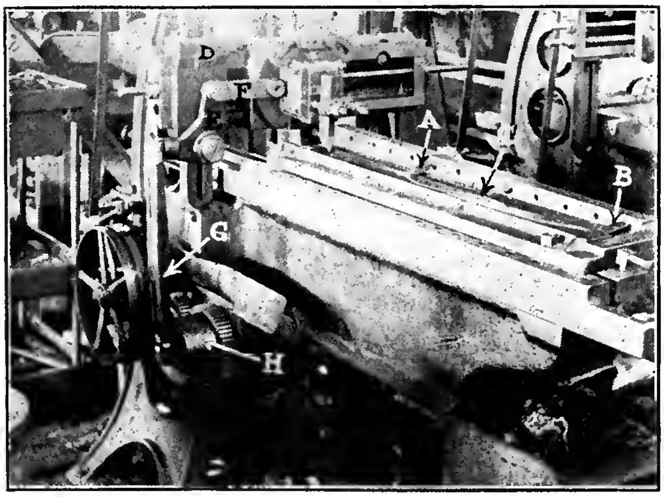

FIG. 1. ATTACHMENT FOR GROOVING GIBS.

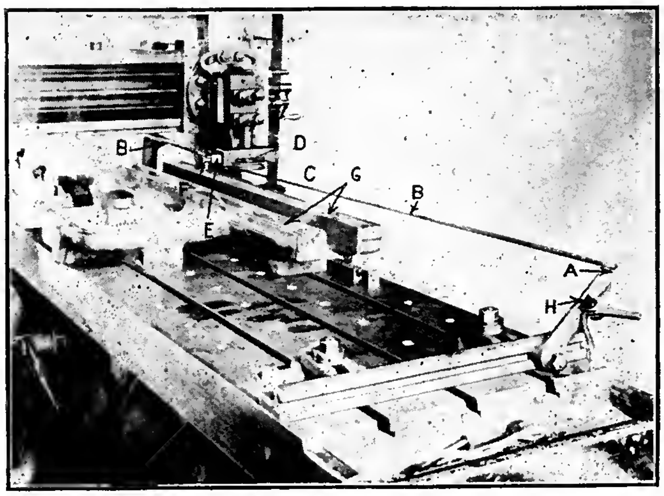

FIG. 2. ATTACHMENT FOR GROOVING FLATS OR BEVELS.

not in use, the whole apparatus may be detached and the planer employed as usual.

Another somewhat simpler device is shown in Fig. 2. An arm A is fastened to the planer table, as shown. A piece of window cord is run from this arm, wrapped once around the grooved pulley C, and then fastened to another arm at the back. The hub of the grooved pulley is turned eccentric at D, so that as it turns the slide E, carrying the tool F, is given a reciprocating motion. Now it will be plain to the reader that as the planer table travels back and forth the cord will cause the pulley to revolve, and when properly set, the tool will cut oil grooves, as shown at G. This device has the merit, that while not as workman-like as the first described, it is easily made, and can be placed on any planer without altering the mechanism in any way.

When grooving V's the head is tilted, as shown in Fig. 3, but otherwise the parts are left as for flat work. This is an advantage not possessed by the other device.

FUSIBLE PLUGS FOR BOILERS.

AN investigation of fusible tin boiler plugs, just completed for the Bureau of Standards by Dr. G. K. Burgess and P. D. Merica, will probably result, says the Iron Age, in the substitution of a new series of specifications for those heretofore employed by the Steamboat Inspection Service, the American Society of Mechanical Engineers and the Interstate Commerce Commission. The results of the investigation indicate that through the lack of technical knowledge on the part of manufacturers and users of the behavior of tin plugs containing relatively small percentages of impurities this safety device has been rendered practically valueless in the average boiler. By the use of simple precautions suggested by the Bureau's experts, it will be entirely practicable to produce plugs that may be relied upon to fulfill their functions under all conditions.

Fusible Plugs and Their Function.

The fusible boiler plug in its usual form consists of a brass or bronze casing with external pipe thread, filled from end to end with a fusible metal or metal composition which has a melting point around 480 deg. F. These plugs are fitted at various places into the boiler, in the flues, tubes or combustion chamber, in such a position that they are about 1 in. or more above the dangerous low water level, with one end on the fire and one end on the water side. As long as the water level in the boiler is above these plugs, the temperature of the latter remains below the melting point of the filling, but if the water falls much below the level of the plug, opportunity is given for local overheating and the filling of the plug then melts and is blown out.

Tin of Plug Changed to Tin Oxide.

Tin seems to be the metal used at present almost exclusively as the fusible constituent of such plugs and is required by all standard specifications. It would seem to be in this respect a desirable metal, having a low melting point, being only slightly corrodible and easily obtained pure. Its desirability in this respect is nevertheless to some extent called in question by the results of the investigation which has just been completed by the Bureau of Standards. This inquiry was undertaken to determine why certain plugs have been found intact in boilers which have exploded as the result of low water and consequent overheating of the boiler plates.

Heavy loss of life occurred as a result of one of these explosions. The plug in this case was sawed open longitudinally and was found to contain traces only of the original tin, imbedded in a dirty, greenish matrix, which was ascertained to be largely tin oxide, and which upon test showed a melting point about 2,900 deg. F. This oxide was distributed in such a form and quantity that it held the pressure of the boiler and would not have melted until the bronze of the casing and even the steel of the boiler had melted. It is obvious from this examination that when reliance is placed upon such a plug to give warning of dangerous boiler conditions it is looked upon as an actual source of danger instead of safety.

Plugs of Faulty Manufacture.

The question thereupon arose as to the source of the tin oxide, as to whether it was there originally, or had been formed by corrosion, and if so, is the cause for its comparatively rare occurrence in such plugs to be sought wholly in the different operating conditions of the boilers, or is it a fault in the method of manufacture?

A request was made of the Steamboat Inspection Service that more plugs be sent in to the Bureau for test, including both new plugs and those which had been removed by inspectors. About 1,050 plugs were subsequently received, of which about a hundred had been in service varying from 4 to 12 months. The entire collection represented the products of 105 firms of manufacturers. After these plugs were tested for dimensions, they were sawed open axially through the centre, and the form and condition of filling observed. Particular attention was paid to the presence of oxide, scoriae, blow holes and other faults originating either in the manufacture of the plugs or during their service.

The Bureau's investigation demonstrated that the correct design of a fusible plug is of more importance than might be supposed. Owing to the difference in the coefficients of expansion of the casing and of the filling of such a plug and to the existence of an allotropic change in tin at 320 deg. F., there will be interplay between casing and filling unless the design is such as to support the filling rigidly in the casing and the adhesion between the two is excellent. A smooth bore "tapering evenly from end to end" is, therefore, not to be recommended, and it is noted that the Steamboat Inspection Service has recently allowed a fine inside thread. In the opinion of the Bureau's experts, however, there is no reason why a thread should be allowed and not other types of recess or projecting shoulder to keep the tin filling rigidly in place.

As a result of the examination of the sample plugs and an investigation of the reported failures and of certain tests made at the Bureau, it appears that the failures of tin plugs are of two types; first, those in which the oxide forms as an interlocking "network" throughout the tin of the filling and, second, those in which the oxide forms as a solid, hard mass at the fire end of the plug. An explanation of the formation of the network was found in the presence of zinc in amounts varying from 0.3 to 4.0 per cent. The experts also reached the conclusion that plugs containing zinc in quantities mentioned were apparently in good condition when inserted, but subsequently underwent a progressive change, becoming no longer fusible in the sense that they would melt below a temperature sufficient to fuse the steel plates of the boiler.

Zinc Should Not be Used With the Tin.

"The fact that stands out most strongly throughout this investigation," says the report in conclusion, "is that zinc should not be present in the tin fillings of fusible plugs. The lowest zinc content actually found in any of the plugs analyzed, which displayed the network type of oxidation, was 0.3 per cent., but this cannot be accepted as the actual lowest value of the zinc content at which oxidation can take place. Furthermore, although zinc is, because of its greater corrodibility, most dangerous when coalesced into a network of structure such as is developed upon heating to about 180 deg. C., other metals which do not form solid solution with tin may also cause the formation of this structure, as, for instance, lead.

It seems then that in such plugs tin must be used which is as free as possible from zinc and lead. This statement is made notwithstanding the apparent fact that if zinc is present a small content of lead is actually beneficial. It is better to prevent this oxidation by using pure tin than by using lead with tin containing zinc."

Principles of Laying-Off Cylindrical Intersections--V.

By J. W. Ross

The more or less special nature of the work involved in the making of sheet metal piping has caused many manufacturers to avoid this class of work, with the result that when a job has to be handled, there is frequently considerable unnecessary loss incurred through errors in laying off material. The examples treated by the writer of this article should form a valuable reference to many manufacturers on ordinary as well as special occasions.

RECTANGLE INTERSECTING A CYLINDER.

THE same principles are adopted in this or similar problems as was adopted in the preceding problems of intersections. Fig. 38 shows the perspective, Figs. 39 and 40 the elevation views. Enough information can be obtained from the drawings without any explanation. Develop the patterns, Figs. 41 and 42, in precisely

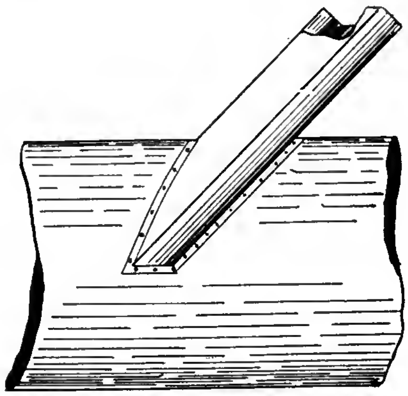

FIG. 38.

the same manner as the problem shown in Figs. 34 and 35.

Connecting Pipe Between Two Circular Tanks.

The perspective view, Fig. 43, and the elevation, Figs. 44 and 45, show a connecting pipe between two circular tanks. This problem deals with heavy plate. The patterns are developed in accordance with the instructions given on heavy plate in development of the problem shown by the Figs. 18 and 19.

Y or Three-way Pipe.

The intersection of three pipes forming a Y is shown in the perspective drawing, Fig. 49, and the elevation view, Fig. 50.

Construction.

Draw the horizontal line, 7° 1°, Fig. 50, equal to 1 inch. Bisect at 4° and erect the perpendicular 4° 7^1. Locate the point 4^x, $\frac{7}{8}$ in. from 4°. At an angle of 45 degrees to the horizontal line draw the inclined line 4^x 10. Also line 4^x 4, each equal to $1\frac{5}{8}$ inches. At right angles draw the line 7 4 1 equal to 7° 4° 1°. Draw the line 7 7^1 parallel to 4^x 10—to the intersection of the vertical

*Note: The reference letters and numerals in the text, i.e., G^2, 7^2, etc., correspond with those of the illustrations indicated as G'', 7'', etc.

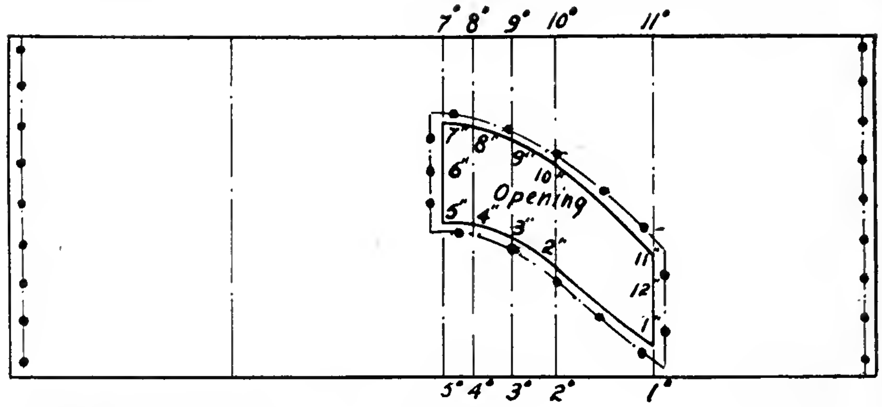

FIG. 42.

line 4° 7'. Also parallel to 4^x 10 draw the line 1 1^x to the intersection of the vertical line 1° 1^x. Connect 4^x to 1^x. Construct the left-hand side of Fig. 50 in a similar manner. Then 7^2 4^x 1^x defines the

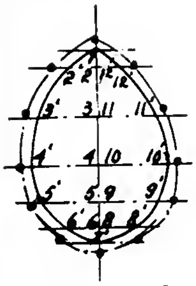

FIG. 47.

FIG. 48.

mitre line for the lower course, and 1^x 4^x 7^1 for the inclined course. With O as centre describe the plan view, 1 4 7 10. Divide into 12 equal spaces. Project these points to the mitre line, 7^2 4^x 1^x. Again, with X as centre describe the plan view of the inclined pipe as shown by the circle 1 4 7 10. Divide into 12 equal spaces. Project these points —parallel to 10 4^x—to the mitre line

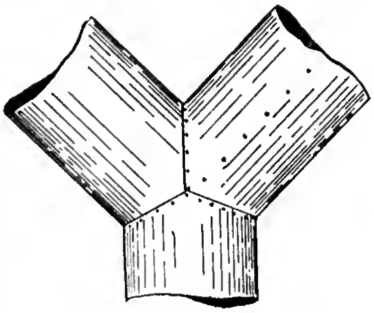

FIG. 49.

7^1 4^x 1^x. Draw the stretchout 1° 1°, Fig. 52. Divide into 12 equal spaces. Transfer the measurements 1° 1^x, 2° 2^x, 3° 3^x, etc., Fig. 50, to their similar lines in Fig. 52. Draw a curve to define the mitre or flange line; add the laps. Space in the rivet holes. Similarly transfer all the

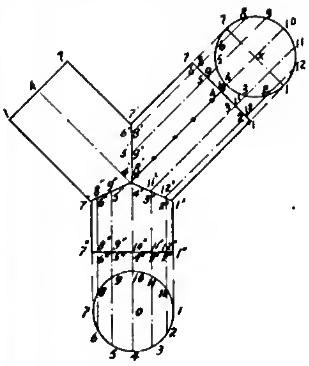

FIG. 50.

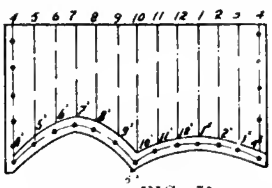

FIG. 51.

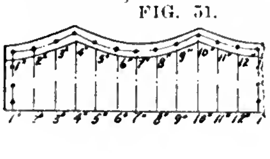

FIG. 52.

element lengths of the inclined cylinder to their respective points on the calculated stretchout, Fig. 51. Fig. 51 will be the templet for both the inclined cylinders. The preceding problems cover fairly well the various intersections developed by parallel lines. In the next article conic intersections will be dealt with, showing the radial method.

GRINDING AS A MANUFACTURING PROCESS.

By Howard W. Dunbar.

GRINDING for manufacturing operations, as distinguished from grinding simply for accuracy, such as tool room grinding, requires that the work in hand be given intelligent thought by the manufacturer. The grinding machine, alone, without the aid or intelligence of the engineer, superintendent and manager, can never be successful.

It is not the intention of the grinding machine manufacturer of to-day to depreciate the value of the lathe, milling machine, planer or any of the other more commonly known forms of machine tools, but rather, owing to the presence of the modern grinding machine, the value of these other forms of machine tools is enhanced; the only change in the conditions to-day being that the modern grinding machine calls for a greater effort on the part of the makers of lathes, milling machines, planers, etc., to make good, heavy, well-built machines with which to assist the grinding machine in the production of work more quickly and economically. A great many of the differences of opinion are purely psychological, and because tradition has said, do so and so.

Importance of Turning.

In the manufacture and use of the grinding machine the question of turning is of the greatest importance, and in turning is the greatest of all savings, when we have the modern grinding machine to grind accurately to size and with good finish. Here is made possible the cheapening of the turning operation, but to do this we must have good, heavy lathes, capable of performing the work in the manner best suited for the grinding machine operations. As a rule, most machine tool users do not consider this.

The proper relation of turning to grinding (and by this is meant the way and manner in which the operation is performed, the amount of stock removed by the lathe, the amount of stock removed in the grinding machine, the number and depth of the cuts, etc.) can only be determined after scientific investigation of each piece to be finished. No rule can be laid down whereby it becomes an established fact. Sometimes it is most profitable to grind without turning at all; more times it is not. The statement of this fact generally starts every one to grinding from the rough, whereas each piece should be studied, and the proper operations applied, if you wish to determine the cheapest way of producing your parts.

Economical Production of Cylindrical Work.

This brings us to one of the points for consideration—the most economical method of producing cylindrical work. To start with, let us make a radical departure from the now common form of organization in most all machine shops. It is our firm belief that the turning department and the grinding department should come under the same foremanship, as the finished part requiring grinding is only produced at least cost when the proper relationship of the turning operation to the grinding operation has been determined. So, by placing the responsibility of the final cost with one man we are working towards the end which must result in the most economical production of round work.

The grinding machine to be successful requires that all tradition be thrown to the winds. To illustrate: Tradition tells a lathe operator that he will save time in turning by taking one cut, and that a deep one, if his lathe is powerful enough. Investigation of the proper use of the grinding machine shows that in many cases the work can be produced for less cost if two or even three cuts are taken in the lathe, for the reason that sometimes the work is too frail to stand the rapid traverse feed with one deep cut. In such cases two cuts, even three, will sometimes prepare the piece properly for the grinding machine in less time than the single cut with slower traverse feed.

Again—tradition tells the lathe operator that if he turns his work very close to size it will require less time for grinding. This is true, but it may not be true that the work will cost less thereby.

In the case of long, frail work like countershafts, etc., tradition tells us they must first be turned and then ground, and it is true that in producing such a piece, 1-16 in. in diameter can be removed in less time in the lathe than it can be done in the grinding machine, but it is not true in all cases that it will cost less, for the reason that when such pieces are turned rapidly with one single cut in the lathe, although only 1-16 in. is removed, they must be straightened before they can be ground.

We have in mind a piece of work that required six minutes for turning the roughing cut and nine minutes for grinding the roughing cut, but the straightening of this work after turning required nine minutes. So in this

case the turning was literally thrown away. These pieces were afterwards rough ground, taking off the 1-16 in. in nine minutes, requiring no straightening after the rough grinding operation and the workman then had simply to finish grind in the usual manner.

It must not be understood that we recommend grinding without turning in all cases; we do not. The reverse is usually true, but it is also true that thousands of dollars are thrown away every year because shops follow tradition and turn everything before grinding and thousands more are lost because shops following tradition, turn work too nicely and too expensively and too close to size.—Grits and Grinds.

COAL-TAR PRODUCTS USED IN MAKING EXPLOSIVES

By C. G. Storm.

MONONITROBENZENE, commonly known as "oil of mirbane," is little used in the explosives industry because of its volatility, although it is sometimes used as a minor constituent of certain low-freezing dynamites and other types of explosives. It is used much more extensively in soaps, lubricating greases, etc., mainly for the purpose of imparting a more or less agreeable odour. Furthermore, it forms an intermediate product in the preparation of aniline and its many derivatives.

Among the aniline derivatives of importance are tetranitroaniline and tetranitromethylaniline, both of which have in the past few years assumed prominence as detonating explosives for projectiles, mines, and torpedoes. Many other derivatives of aniline have been found to be applicable as stabilizers or as gelatinizing agents in nitrocellulose smokeless powders. Among such substances are methyl or ethyl phenyl urea, phenyl benzyl ether, phenylacetanilide, formanilide, and diphenylamine. The latter is, however, the only one which has been used in this country. The nitrotoluenes are more extensively used in the explosives industry than any other nitrosubstitution compounds, being employed chiefly for sensitizing certain types of ammonium-nitrate explosives and for lowering the freezing point of the low-freezing dynamites.

In the absence of exact statistics, a rough estimate places the amount of the various grades of nitrotoluenes used in the low-freezing dynamites manufactured in this country in 1913 at about 2,000,000 lb., while in the "permissible" explosives employed in coal mining probably 250,000 lb. of the same materials were used during the same year.

Pure crystalline trinitrotoluene has proved one of the most efficient explosives for use in explosive shells, torpedoes, and mines, and is extensively used by almost every important military service, including that of this country. In recent years it has also come into use as a substitute for a large proportion of the mercury fulminate in detonators (blasting caps) and as a charge for detonating fuse.

The nitronaphthalenes are used to some extent, chiefly as sensitizers, in the "short-flame" permissible explosives of the ammonium-nitrate type. Certain derivatives of these compounds, the alkaline salts of nitronaphthalene sulphonic acids, produce, when mixed with sodium nitrate and other ingredients, explosives suitable for coal mining.

Picric acid (trinitrophenol) and certain of the picrates are highly important as military shell explosives; the acid is also employed in surgical dressings for burns and wounds. The manufacture of these compounds depends entirely on phenol (carbolic acid) as a raw material.

The possibilities of the use of the nitroderivatives of coal-tar products in explosives are far greater than is indicated by the above brief summary. Much investigative work on such compounds is being carried on in this country as well as abroad, from which important developments in the explosives art may result. The Bureau of Mines has instituted a systematic research into the preparations and properties of these nitrosubstitution compounds with a view to studying their possibilities in the explosives industry. — From Technical Paper 89, the Department of Interior, U.S. Bureau of Mines.

GERMANS TRY TO GET SHEFFIELD STEEL

IT is reported that the Sheffield Chamber of Commerce has recently investigated some ingenious attempts to obtain high-speed steel and high-class tool steel from Sheffield manufacturers for the use of alien enemies. These special tool steels are necessary in all shops making munitions of war, and as Germany in peace time imported considerable quantities from Sheffield it is probable that she is feeling the necessity of new supplies. The attempts to place orders have been made with great circumspection and it was only the special knowledge of the president of the Sheffield Chamber that brought about the exposure in one case. The Chamber has issued a notice to manufacturers warning them that all inquiries should be carefully scrutinized "in view of attempts now being made to secure high-speed and high-class tool steels for the use of alien enemies. Manufacturers are asked to exercise the same caution even where orders are offered by London agents.

CUSTOMS RECEIPTS SATISFACTORY

CUSTOMS receipts for the month of August, according to official figures issued by the Department of Customs, Ottawa, amounted to $8,330,604.04. This total is very slightly under that of August, 1914-15, when the receipts showed the result of heavy ex-warehousing of bonded liquors in anticipation of the tariff increase. Very large quantities of imported liquors, it will be remembered, were taken out of bond in an effort to escape the heavier duties which, it was expected, would be imposed in the Finance Minister's war budget. Even with this abnormal collection of duty on liquors, the receipts for August last year exceeded those of last month by only $53,202.50.

The statement for this year is accordingly regarded by officials of the Customs Department as in every way satisfactory. The same is true of the statement for the five months of the fiscal year, as compared with ante-bellum months of last year, and making the same allowance for the ex-warehousing which took place in August. The receipts for the five months of the present fiscal year amounted to $36,731,165.01, as against $37,125,639.92 for the corresponding period of 1914-15.

LACHINE CANAL TRAFFIC.

DURING the month of August just closed, the amount of grain brought through the Lachine Canal was 4,651,079 bushels less than what came through in August, 1914. Returns made public yesterday afternoon by the canal authorities indicate a falling off in practically every line of activity connected with the waterway. Coal shipments decreased by 36,661 tons, while not a single sack of flour came down the canal last month, as compared with 102,972 recorded twelve months ago.

Tonnage Lower

There were 1,116 trips through the canal last month, fewer by 347 than last year. The tonnage operated was 589,317 as against 780,352 tons in 1914. The passengers carried through the canal and down the Rapids were 20,453, or 8,206 less than in August, 1914. This last total showed an improvement, however, over the previous month. The cargo tonnage last month was 470,930, a decrease of 190,382. The number of trips light in August, 1915, was 369, as compared with 515 in August, 1914.

For the whole season to August 31 the total grain coming through the canal has amounted to 25,008,924 bushels, just 17,222,206 bushels less than for the same period in 1914.

The propeller efficiency of aeroplanes in practice is about 60 per cent.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

BAND TURNING LATHE FOR 4.5 H.E. SHELLS

THE Jenckes Machine Co., Sherbrooke, Que., have placed on the market a new band turning lathe for 4.5 high explosive shells, particulars and illustration of which are as follows:—

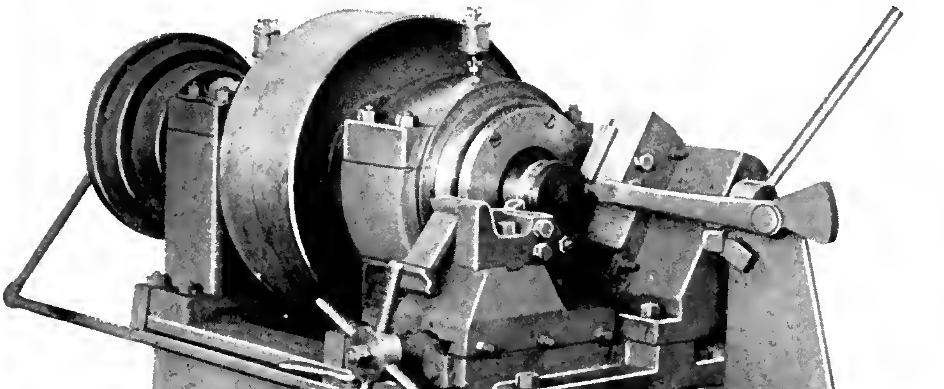
The bed is of the heavily ribbed flat top type, and is mounted on legs of standard type. In place of the regular headstock, two substantial capped bearings are used, each being secured to the bed by four suitable bolts. The bearing caps are machined, and are held by four studs. The bearing is 6 in. diameter by 7 in. long, being babbitted, bored, and finally scraped to the spindle. The spindle is a hollow steel casting, turned all over and finished by grinding. The drive is through a 22-in. by 8-in. clutch pulley mounted on the spindle and bronze bushed.

The clutch is of hard maple, cone type, and the full size of inside of pulley. It is operated by a compressed air piston controlled by a valve easily within reach of the operator's left hand. The clutch mechanism is all built into the spindle, and when in use has no tendency to move the latter endwise or cause end friction. Means are provided, however, for taking up end play of the spindle should wear occur. The chuck is operated by compressed air and is of the draw-in type. It is bolted into the large end of the steel spindle and controlled by the same valve mechanism as operates clutch.

The tool slide base is heavy and is clamped immovably to the lathe bed. The front or roughing tool is fed in by screw and hand wheel to a dead stop, and leaves a light cut for the finishing tool, while the finishing tool is mounted to the rear and above the work. The tool can be adjusted to pass down behind the shell, and in passing shave the band to size. The feed is by lever and pinion.

The tools can be removed for grinding, and be replaced with precision. They are held in steel blocks by a clamp gripping the dovetailed portion of the tool. The tools are formed of "Novo Superior" steel, $4\frac{1}{2}$ in. long. The shell is located by a swinging finger on front tool block before the chuck is tightened.

A hinged scraper rest is provided on front tool block for removing the ragged edge at each side of band after tooling. No countershaft is required, the lathe being driven direct from the main line shaft of motor. About 10 horse-power is required to operate the machine, together with a small quantity of compressed air at available pressures.



COPPER BAND TURNING LATHE FOR 4.5 HIGH EXPLOSIVE SHELLS.

A NEW "GARDNER" GRINDER

IN bringing out this new machine, the manufacturers, the Gardner Machine Co., Beloit, Wisconsin, claim to have developed a disc grinder which has immeasurably broadened the possibilities of the disc wheel; a disc grinder which will not only handle with greater speed and accuracy all the work that their earlier types do, but a great number of additional operations which heretofore had been proven unsuited to this manner of machinery. It is a complete grinding unit, each machine being equipped with dust exhauster, water system and cast iron hood.

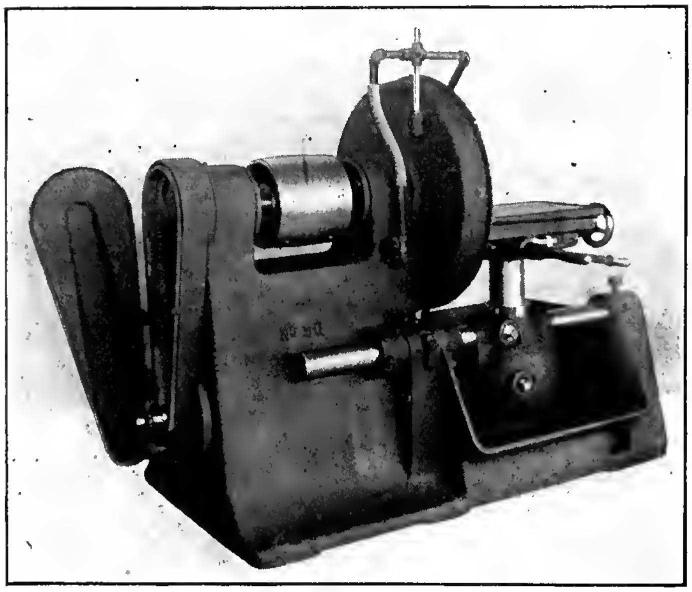
The machine is of unusual weight and rigidity. The total weight, without skids or crating, is 5,000 pounds. The spindle is made from the best crucible steel, turned and accurately ground to 3 inches in diameter. It is mounted in S.K.F. radial ball bearings of larger size than recommended by the manufacturers. The end play is also taken on thrust ball bearings of the same make. The spindle pulley is 12 inches in diameter, with a face for 10-inch double belt. The complete spindle is perfectly balanced and runs without sign of vibration.

The 4-inch diameter rocker shaft and counter weight are a one-piece casting, and weigh in the rough approximately 500 pounds. It is of particular importance to note that the rocker shaft has a

bearing at each end, and that it oscillates in the bearings when the table is rocked back and forth across the grinding wheel. This style of construction results in surpassing stiffness and rigidness, all of which make for greater accuracy and output. When the work being ground is forced against the grinding wheel, it will be understood there would be a tendency for the rocker shaft to move to right in its bearings. The heavy clamp collar just outside of the left bearing prevents this action. The other collar at the right serves two purposes: It is locked to the shaft against the end of the bearing, preventing the shaft from working to the left. The ledge on the under side of this collar and forming a part of it is provided with a curved, elongated slot, which acts around the stop screw. By adjusting this collar on the shaft and locking with the set screw, the limits of the oscillating motion of the table may be regulated.

The table column and top are solidly and rigidly constructed. The column is 5 inches in diameter, and when raised or lowered works within the counterweight, directly over the centre of the rocker shaft. When raised to the required height, it is held in position by the two locking screws passing through the left side of the counterweight. The graduated clamp collar, situated above the counterweight on the column, is employed when it is desired to set the table at an angle with the grinding wheel.

The finished top of the table has three ½-inch T-slots and measures 18 inches long by 10 inches wide. It is surrounded by a depressed channel, with the bottom cast on a down pitch, so that when wet grinding is done the water will rapidly drain into the basin below. The feed mechanism of the table—that is, the travel towards the grinding wheel, is a feature of this machine. Provision is made for either lever, screw or spring feed. When the lever feed is desired, the screw wheel is disengaged by removing a taper pin through its hub, and travel is accomplished by a pinion on the inner end of the lever shaft working in a rack attached to the under side of the table top. By lifting on the lever, a leverage of 56 to 5 is secured. The other handle mounted on the lever shaft, and which projects towards the front is used to assist in rocking the table. The positive screw feed is obtained by replacing the taper pin and turning the hand wheel to the right. A spring pressure of from 1 to 300 pounds can be had by turning up on the screw hand wheel when the latter is disengaged. When the spring feed is employed, the hand lever is used for giving any additional pressure wanted and for locking the table away from the grinding wheel. The micrometer stop screw in front accurately governs the forward movement of the table. The ways for the table top are formed by two heavy, flat gibs, and are thoroughly protected from grit or dust.



A NEW "GARDNER" GRINDER.

It should here be mentioned that this machine carries either a 30-inch diameter by 1¼-inch steel disc wheel or a 20-inch "Perfection" ring wheel chuck. The abrasive ring wheel is used when it is desired to do wet grinding and the disc wheel when dry grinding is done. The cast iron hood terminates at the extreme bottom with two openings, one for water and one for dust. When one of these openings is in use, the other is closed with hinged covers provided. When water is used, it falls into the main basin, from which it overflows into the removable reservoir shown at the rear of the machine. From here it is pumped up through the machine base and out at the adjustable nozzle directly on the work at the point of grinding contact. This water pump is of the gear type, and is driven from the machine spindle by sprockets and chain. The dust exhauster is contained within the machine base and is driven by belt. It is connected to the bottom of hood and discharges at the lower back of the machine. Here a thimble is provided for attaching to pipe. The front of the hood is enclosed with cast iron sections, one or more of which can be removed or inserted, making the opening adjustable for different sizes of work. The chain and belt driving the water pump and exhauster respectively are encased with a cast iron guard having a hinged door.

EFFICIENT USE OF LABOR IN THE FOUNDRY

By J. S.

SINCE the war began the writer has worked in four foundries, all of which have experienced the so-called shortage of labor. In such cases the employer's first thought should be as to whether he could increase the output of the men without overtaxing their strength, by supplying the materials to enable them to work quickly, but how many firms give their moulders or coremakers even all the tackle that should be regarded as necessary?

There are some, but very few founders who realize that a man cannot make his work safe and sound without the necessary tackle, and, moreover, they ignore the fact that tackle needs overhauling and repairing or replacing at times. There are few firms who keep a man to attend to the latter. The foreman or charge hand is perhaps supposed to do this, but the numerous other duties that keep him fully occupied, such as loading and unloading moulding boxes off the stove carriage, finding places to drop them so that they can be cored up and cast, giving jobs out, getting castings out, finding the defects and cause of bad ones, pouring metal when casting time comes round, and other items too numerous to mention that do not come under the heading of moulding or core-making, allow him little time for systematic attention to the men's tackle.

As an instance, two moulders were given employment in a certain foundry and were brought to the foreman or charge hand by a clerk from the office. They were given a pattern to mould, told to "get down here," and shown the box the casting had to be moulded in. The foreman then walked away.

Now, no doubt, these men were entire strangers to the place, and perhaps had not made a casting so heavy for five, ten or twenty years; or, on the other hand, they may have just come from a shop

where they had been on that class of work for years. They rammed the bottom part, turned the box over and proceeded to ram the cores up in green sand. The pattern was for a bed plate of 3 to 4 tons weight, made as a shell pattern to leave its own cores. This system needs a good, strong cast-iron grid to carry the body of sand in the lift, but the men had to make shift with any old cast-iron grid that they could find or make suitable, and these were mostly in halves or with prods off, staples missing, etc., all of which entailed more loose wrought irons.

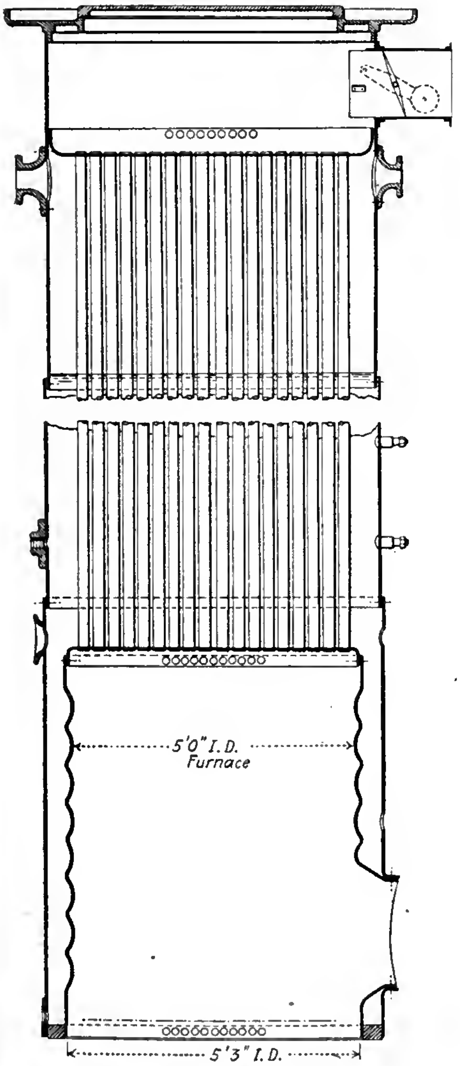


FIG. 1. SIMPLE DESIGN OF VERTICAL BOILER WITH CORRUGATED FURNACE.

In cases like this, where the proper tackle is missing, the moulders often "risk it," and frequently there is a mishap, but who is to blame, the moulder for not using tackle which he had not, and although probably using his best endeavors to make the best of a bad job?

A moulder or core-maker who has acquired the methods of one firm is often not allowed to try them in another shop. In many jobs there is an alternative way that could well be adopted; but it makes a sensible man very cautious in following methods he considers best when the foreman, after the job is well started, pounces down upon him with "have you done this," or "don't do that," and finally orders the job to be started all over again on the customary methods of the firm (which, as a rule, are the foreman's methods), though there may perhaps be no better way than that followed by the new hand.—Foundry Trade Journal.

CORRUGATED FURNACES FOR VERTICAL FIRE TUBE BOILERS.

By F. W. Dean, Boston, Mass.

I HAVE been impressed for many years with the value of corrugated furnaces for vertical boilers, but only recently have actually used them. By the use of such furnaces, staybolts are done away with, and as there appear to be no disadvantages in the furnace this is a most important feature. As many hundreds of staybolts are avoided in each boiler there are just so many less opportunities for breakage and needed repairs. In the staybolted firebox it is necessary for safety to drill holes in the ends of the staybolts in order to know when they are broken.

The simplicity of vertical boilers with corrugated fireboxes must commend them to owners and makers. In the boiler shop the operations of building are of the simplest and most rapid kind. Again this type of firebox provides for expansion and contraction of the tubes in a safe manner, but on account of its somewhat flexible character it should be assumed that it is advisable to support the lower tube plate as near the edge as practicable. The ordinary firebox is rigid vertically and supports the edge of the lower tube plate, but as the corrugated firebox has slight elasticity it is best to hold up as much of the tube plate as practicable by the tubes and provide little or no elasticity in the tube plates. The flat and unstayed portions of the upper and lower tube plates should be made equal in diameter in order to balance.

The flanging of the fire door presents no difficulty, but it should be done so that the corrugations coalesce with the conical part. The behavior of the firebox end of the boiler when under pressure led to some speculation, for the area of the fire door opening theoretically unbalances it. When under hydrostatic pressure, various gauges were used for showing distortion, but none could be discovered.

In regard to sizes of such furnaces the catalogue of an American maker gives 60 in. as the maximum inside diameter, but, as a matter of fact, this concern can make them up to 72 in. diameter, and almost 1 in. thick. They have been made slightly larger in Germany and the furnace of the larger boiler illustrated was obtained in that country. If the inside diameter is 72 in., the grate will be 3 in. larger or 75 in. and the grate area 30.68 sq. ft. It is easy enough to generate 200 h.p. on a grate of this size with considerable capacity for forcing beyond that, and there is no difficulty in providing the heating surface for such horsepower.

In the matter of pressure, a furnace 72 in. in diameter and 0.95 in. thick will carry 200 lb. If there were sufficient demand for larger furnaces they would probably be forthcoming. The theory of heat transmission through plates, and experience, show that thick furnaces, especially if without riveted joints, are objectionable.

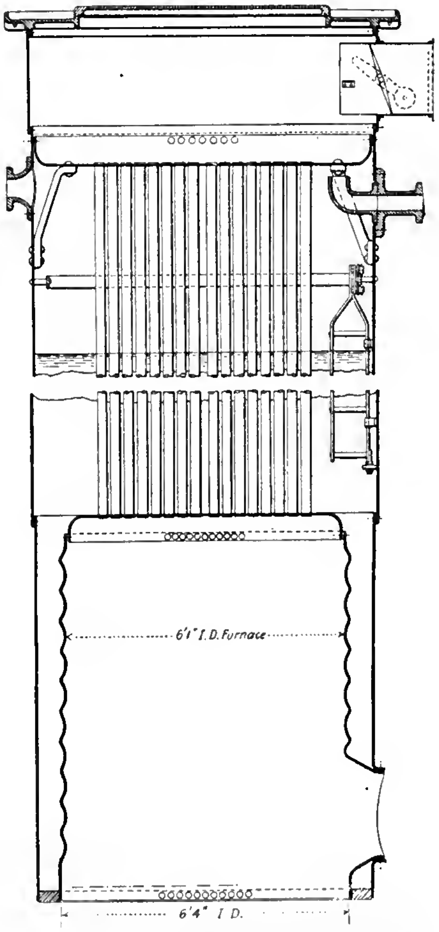

FIG. 2. LARGER BOILER OF THIS DESIGN WITH INTERIOR ACCESSIBLE FOR INSPECTION.

The introduction of corrugated furnaces for the fire boxes of the vertical type of boiler is, I think, a real improvement in steam boilers. The type possesses the important qualities of giving maximum and permanent economy, superheating the steam from 20 deg. to 40 deg., being free from brickwork and requiring small floor space per horsepower.

Fig. 1 shows a boiler of the simplest possible design, two of which have been in use for a year and a half, and Fig. 2 shows one with the interior accessible for inspection and cleaning which has been in use a few months only.

PEACE-TIME PURSUITS DUE FOR DEVELOPMENT

THE much heralded visit to Canada of D. A. Thomas, the representative of the British Ministry of Munitions did ultimately materialize. Its duration was brief, its programme commonplace and its value problematical. What Mr. Thomas did not know concerning our munitions output and facilities to maintain and enlarge same previous to his advent here were, we should say, comparatively easy of acquirement during his sojourn in our midst. Appearances are rather favorable to a quite generally developing impression that the Thomas visit bears on its face the sole purpose construction—to find out our minimum—with—contentment, so far as the placing of further shell contracts are concerned.

The war is now over thirteen months old and for the major portion of this period Canadian engineering and metal-working plants have been contributing their called-for quota of various type shells. Further, we have organized and equipped to maintain an indefinite quantity supply and have said so earnestly and often. It has, however, seemed to us that compared with the huge orders for war munitions placed in the United States, we were merely crumb gatherers. Organization of interests engaged in shell production gives at once concrete expression to the dissatisfaction felt and to the desire to have opportunity to supplement Empire service by placing increased shell manufacturing capacity at headquarter's disposal. At least two such organizations are in existence, one being representative of our larger engineering and metal-working plants and another of several of our smaller and medium-size plants.

On more than one occasion we have hinted at the probability of shell manufacture in Canada being in the nature of a stop-gap, basing our opinion on the fact of the unpreparedness of British plants to cope with the then demand for shells. The position in Britain, however, is no longer one of unpreparedness. She is nothing short of being one huge ammunition and war supplies factory, equipped with men and machines drawn from every possible source, home and abroad, and organized to ensure an almost self-contained output which will not only last the war, but settle it as she and the worth-while world desires it settled.

Canada and the United States may both take to heart this fact of the war situation, not only as it refers to Great Britain, but to her Allies as well. Men and munitions have been piling up prodigiously these past months, and outputs have been increasing by leaps and bounds. Lloyd George, Britain's Minister of Munitions, is reported to have given out the following statement relative to the latter: Taking the figure 1 as representing the munitions output of British factories in September, 1914, the figure for July, 1915, is 50 times greater. In August, 1915, it will have been 100 times greater and from there onwards the output curve will continue its upward course.

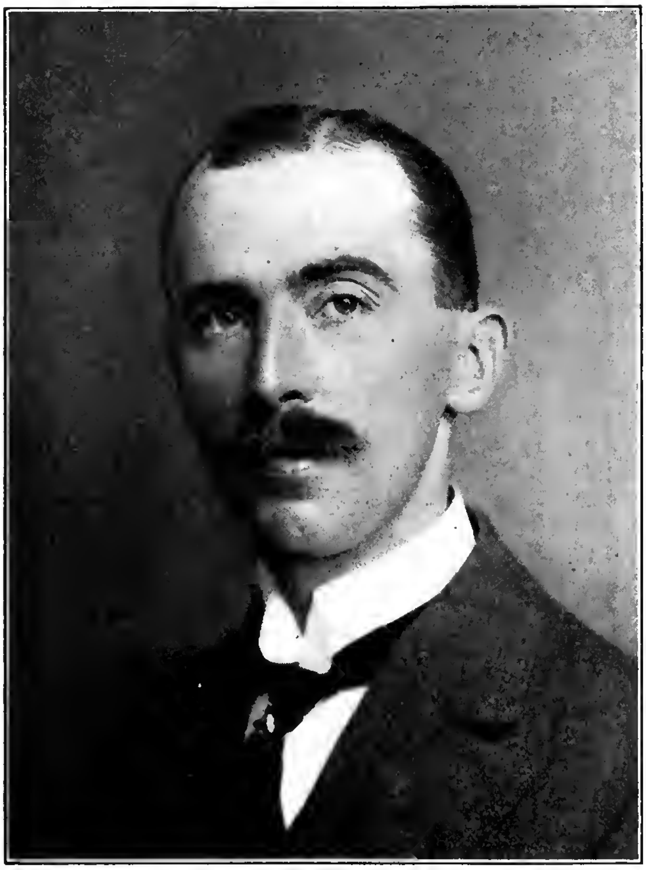
In the past few weeks quite a full realization of the munitions production position in Britain has dawned on the administrations of American financial houses, hence the gallery display of a favorable trade balance while the opportunity is still available. The mission of D. A. Thomas, both here and in the United States, has, we are inclined to believe, been so far as munitions are concerned of a contract-cancelling, stop-order or closing-out nature, and although orders may continue to be placed in both countries while the war lasts, they will be more or less supplemental and comparatively small. In view of this we offer the opinion that contracts will be divided for the most part among the larger and specially equipped Canadian establishments.

Authorities are generally agreed and uncertainty no longer cuts any figure, that an all along the line Canadian crop record has been established. Such a happening in peace or normal times would be the signal for an impetus to every form of industrial and manufacturing development within our borders. A little loosening up here, and a display of old-time enterprise there will easily get good times off to a fair start again. Our engineering and metal-working plant capacity and equipment was never in such shape for handling business—war and peace-time, new and old, home and foreign, and it only needs our big spenders—the railroads to make a beginning, there being the absolute assurance that the little fellows all the way down will quickly join in.

CANADIAN SHIPBUILDERS

THE Collingwood Shipbuilding Co., Ltd., Collingwood, Ont., of which Mr. John S. Leitch is general manager, is one of the most important shipbuilding, engineering and repair plants in Canada, possessing, as it does, two excellent drydocks, commodious building berths with overhead electric crane equipment, engine and boiler shops, foundry and other customary buildings necessary for an up-to-date establishment of its kind. In addition, work is now being carried on night and day producing shells, the company having installed equipment for the manufacture of both shrapnel and high explosive shells.

Mr. Leitch, who is 35 years of age, has been with the Collingwood Company for over three years, and is responsible to the directors for the management of the entire plant. Under his guidance an interesting variety of vessels, with their propelling machinery, has been successfully produced, including such widely different types as 550-foot bulk freighters, powerful bucket ladder dredges for service in the St. Lawrence ship channel, lighthouse and buoy vessels, hopper barges for the Dominion Government services, passenger vessels, etc. Recently an order for two large bulk oil steamers has been secured. It will therefore be seen that the company is enterprising and progressive.



JOHN S. LEITCH.

In addition to new construction, a considerable quantity of repair work is overtaken, the most interesting of the later jobs being the straightening and reconstructing of the large freighter "Howard M. Hanna, Jr.," which came to grief in the memorable gale of November, 1913.

Mr. Leitch, who hails from Portpatrick, in the south of Scotland, gained his technical and practical experience in the three largest British shipbuilding centres, viz., the Clyde, Tyne, and Belfast, having been successively employed by the late firm of Robert Napier & Sons, Glasgow; Swan, Hunter & Wigham Richardson, Neptune Works, Walker-on-Tyne, and Workman, Clark & Co., Ltd., Belfast.

Starting in the shops as an ordinary apprentice, Mr. Leitch has risen rapidly to the highest position in the shipbuilding profession. He resigned from the position of assistant manager with Workman, Clark & Co. in order to take up his appointment in Collingwood

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Toronto, Ont., September 7, 1915.—The Canadian National Exhibition now being held here is exciting considerable interest as usual, and the exhibits in the Machinery Hall are quite up to the standard of previous years, notwithstanding the war. A number of exhibits, as might be expected, feature machinery or materials used in connection with the manufacture of munitions.

The general industrial situation continues to improve, and the large crop which is now practically assured will have a bracing effect in business circles and stimulate domestic trade. The principal development, however, has been recently, and will continue to be in export trade. The expectation of improvement in transportation facilities by increase of tonnage will benefit export trade considerably, it having been handicapped in this respect of late.

Steel Market.

The mills continue working to capacity and the situation in the steel trade is very favorable. This year promises to be a record one for those steel plants who are producing shell forgings and other war material. The business is almost entirely for export, the output being very light for ordinary domestic trade.

The high-speed tool steel situation, is becoming increasingly serious as the demand continues to increase without any corresponding improvement in the supply. Stocks of the sizes most called for are getting very low, and dealers are having the greatest difficulty in filling orders to satisfy everybody as some firms are asking for comparatively large quantities.

Galvanized sheets are firmer following the advance in spelter, but no price changes have been made meanwhile. Makers of galvanized sheets with few exceptions, have either withdrawn from the market or are only quoting on specific tonnages for immediate shipment. The galvanized market is unsettled, and there is little hope of any stability until spelter prices attain fixed level. Prices of galvanized pipe have been reduced following the weakness in the spelter market. The new prices which are given in the selected market quotations represent a reduction of about 10 per cent. The pipe market, however, is unsettled, as the change was decided upon before the recent advance in spelter. If spelter remains at the present level or advances further, higher prices for galvanized pipe may be expected.

Increasing activity prevails in the steel trade in the States and most steel works are now pretty well sold up on their production until the end of the year. The demand for steel rounds for shells is constantly assuming greater proportions, and there is also a heavy demand for barb wire. Prices on bars, plates, and shapes are firmer, and some business has been closed at 1.35c Pittsburgh. Prices on billets are higher, Bessemer being quoted at $23.50, open hearth billets at $24 and forging billets at $30 f.o.b. Pittsburgh. Wire rods have advanced, and are now quoted at $28 Pittsburgh.

Pig Iron.

The market is firm but the general situation is unchanged. There is a good demand for steel-making pig iron, but foundry grades are quieter. Prices are unchanged but firm.

Machine Tools.

The situation in the machine tool market, is much the same as has prevailed during the last few weeks. Many builders of machine tools are in a sold-up condition and deliveries are very backward. There is a fair demand for new tools, and builders of special machines are doing good business. The demand for second-hand tools continues active, principally on account of the difficulty in obtaining quick delivery on new tools.

Supplies.

There is apparently no falling off in the demand for machine supplies and small tools. Prices generally are unchanged but very firm, with the exception of turpentine which has declined two cents and is now quoted at 62 cents per gallon. Prices of leather belting are very firm on account of the scarcity of raw material.

Metals.

There are no important price changes to note this week, and the metal market is steady and firmer. Lead has made a slight advance but prices of all other metals are unchanged. The extraordinary fluctuation in sterling exchange has unsettled the metal market and is having a tendency to restrict business. The general situation, however, is unchanged and business continues good for metals for munitions. The New York Metal Exchange was closed yesterday, being Labor Day.

Tin.—The London Market has advanced slightly, but New York is steady and firm. The fluctuations in sterling exchange are affecting the market and importers are shy at committing themselves to dollar equivalents, and prefer to sell in sterling. Locally tin is unchanged but firm at 39 cents per pound.

Copper.—The market is extremely dull at unchanged prices and there is little of importance to note. The sharp recovery in sterling exchange has greatly improved prospects of export sales. Copper is quoted locally at 19½ cents per pound.

Spelter.—The market for spelter has been restored and good export sales are reported. The market is holding firm, and gives every indication of an advance. Local quotations are unchanged and nominal at 19 cents per pound.

Lead.—The market is firm at the "Trust" price of 4.90c. New York, but domestic enquiry is light. The London market is strong and advancing. Lead has advanced ¼ cent locally, and is now quoted at 6½ cents per pound.

Antimony.—The situation is much the same and the market is quiet. Quotations are unchanged at 40 cents per pound.

Aluminum.—The market is firm and quotations are nominal at 40 cents per pound.

Building Notes

Quebec, Que.—The foundation stone of the new Union Station, was laid by Mayor Drouin, on Aug. 12. H. E. Pringle of Montreal, is the architect.

Vancouver, B.C.—The Department of Public Works, Ottawa, will call tenders shortly on the construction of two large sheds on the new wharf. Approximate cost will be $250,000.

Toronto, Ont.—The Toronto Hydro Electric Commission, 226 Yonge street, are having plans prepared for a sub-station to be erected at St. Lawrence Market, at an estimated cost of $5,000.

Kerrobert, Sask.—Messrs. Badger and Son, of the Badger Flour Mills and Elevator Co., have started work on the construction of a new elevator at this point.

Hamilton, Ont.—Laing & Sons, manufacturing confectioners, have secured a permit for the erection of a factory at 169 and 171 King William street, to cost $8,000. Ground has already been broken for the building.

Winnipeg, Man.—Contractors Hazelton & Webb have been instructed to begin work on the reconstruction of the Scott Block on Main street. Pratt & Ross are the architects and the cost is estimated at $125,000.

Tavistock, Ont.—The Carnegie Library Corporation has agreed to furnish $7,500 for a library in Tavistock, and at the meeting of the council recently it was agreed to provide a site and support the institution to the extent of $750 a year.

From Elevator Manufacture to High Explosive Shells

Staff Article

An outstanding feature of the series of articles being published in these columns on "Shell Manufacture in Canada," and one which is emphasized on each succeeding occasion is that no sphere of mechanical engineering enterprise however far removed its particular product may have been from that of shell making has held aloof from or hesitated to grip the opportunity offered by the latter in all of its variety features. The plant here described is eminently typical of what has been accomplished in the direction above indicated.

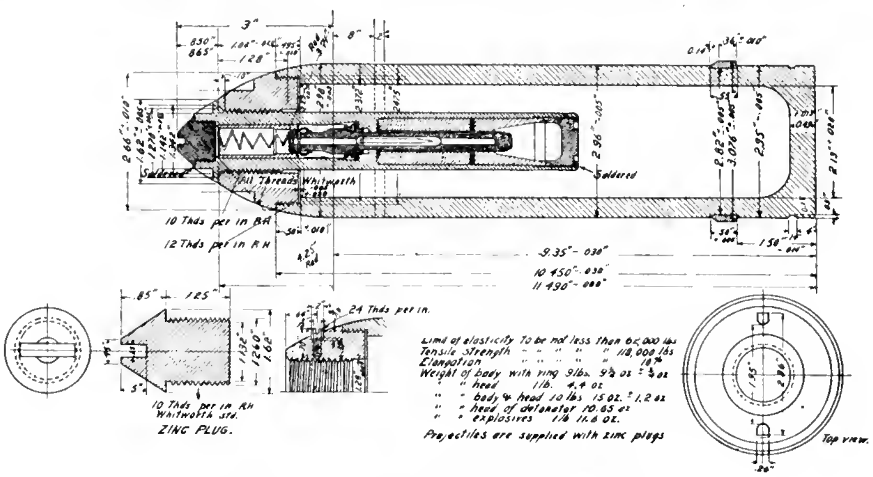
ONE of the chief essentials to maximum output of almost any manufactured article is the employment of special machinery and tools. To meet the requirements of many products the manufacturer, in most cases, must equip his plant with modern, up-to date machinery in order to compete with others, who may be employed in making the same or a similar commodity. In the equipping and perfecting of a plant that is to be used in making some permanent line of manufactured product the need of special machinery is not only an advantage but essentially a necessity.

In the manufacture of shrapnel and high explosive shells the manufacturer must, owing to the impossibility of procuring the desired machines and equipment, devise ways and means whereby he can utilize to the best advantage such tools as happen to be at his immediate disposal.

To get best results, when it is practically impossible to procure suitable machinery, owing to the abnormal demand, the greatest ingenuity must be displayed by those who are called upon to solve each individual problem as it arises, or anticipate them. In no other industry perhaps is this more evident than in the manufacture of shells of the various types.

FIG. 1. ROUGH TURNING SHELL BODIES.

The demand for an increased output of these indispensable pieces of mechanism is so great and our various manufactures are so keen about supplying this demand that more often than not they do not wait until they can be supplied with necessary equipment, but turn to and successfully meet the issue by designing tools and devices that in many cases more than fulfil their most sanguine expectations.



RUSSIAN 3-IN. HIGH EXPLOSIVE SHELL.

The plant description which follows gives a very good illustration of what can be accomplished in the way of overcoming production obstacles, for while it is true that a few new tools were almost absolutely necessary, the greater proportion of the different operations is being done on previously installed machines fitted up with special attachments designed and applied by those in charge of the institution.

Great credit is due to men of the calibre that refuses to be told, or even to think, that certain things are impossible. To meet and overcome the obstacles arising from the inception of a new industry, shows the sincerity of purpose back of the procuring of an order for shells, particularly when time does not allow the delay in waiting delivery of the necessary new equipment.

While the general sequence of operations in the manufacture of the various makes of shells is somewhat similar, the methods devised by the various manufacturers must necessarily differ owing to the class of work to which their particular equipment has formerly been adapted.

The machine tools that would find their home in a large engine plant would not conform to those found in the plant under review, its specialty in normal times being the production of electric elevators.

When various industries, each equipped with their particular line of machinery for the output of their special needs are called upon to manufacture the one special article in unrestricted quantities it requires a ready and active mind to produce results on the machines and tools at their disposal. This particular plant which is now manufacturing the Russian 3 in. high explosive shell has applied to the existent machine tools special devices that are successfully accomplishing what might have been deemed impossible a year ago.

Centering and Roughing.

To fully describe the various useful appliances, the process of manufacture will briefly be dealt with. The rough forging which is secured from the United States Steel Products Co. is first centered on the base, and then taken to a Boye &

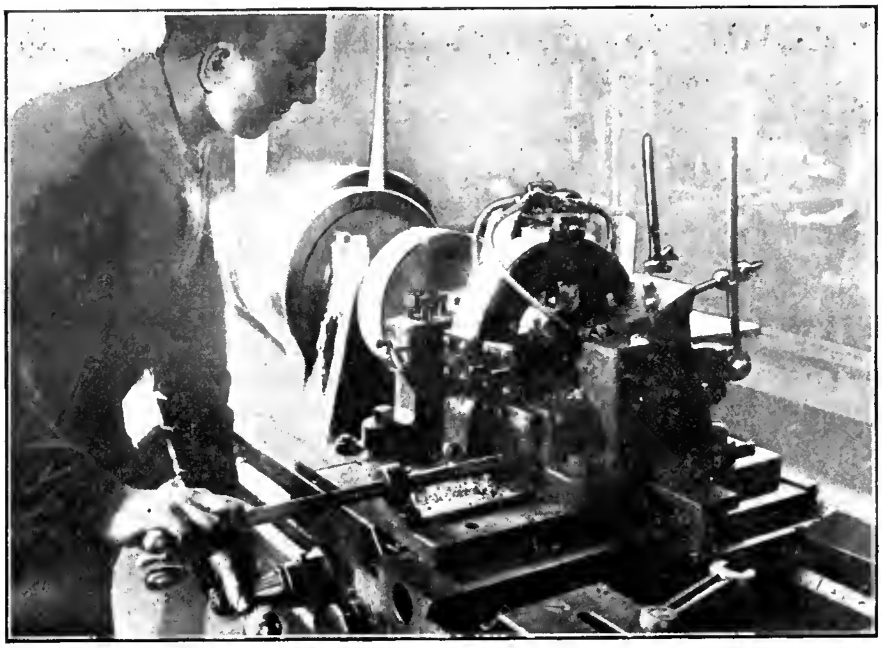


FIG. 2. GROOVING, UNDERCUTTING, KNURLING AND FACING.

Emmes Machine Co. lathe, also to an old "Butler" lathe. A plug is driven into the open end and the shell is placed upon the centres and rough turned as shown in Fig. 1.

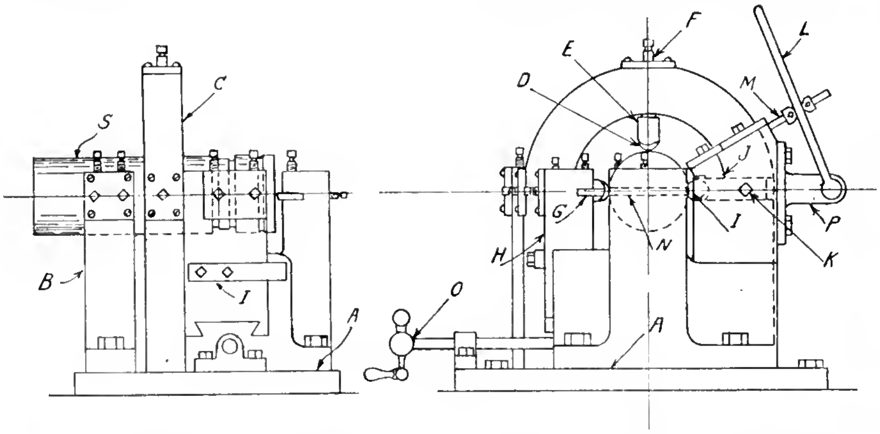

FIG. 3. GROOVING, UNDERCUTTING, KNURLING AND FACING ATTACHMENT.

Grooving, Undercutting and Knurling.

The grooving, undercutting and knurling, also facing the base is performed on a "McDougall" lathe, which is shown in Fig. 2. This operation and the device that accomplishes it indicate the ingenuity of those who have taken in hand the responsibility of production. Fig. 3 shows a rough sketch of the device which originally was intended also to rough turn the body, but on account of the low limit allowance on these shells and the possibility of tearing and marking, the roughing is done previous to this and the other operation done separately.

The main casting A of the device is bolted to the saddle of the lathe, the piece B being for the roughing operation but, owing to the possible faults already stated, was dispensed with. The steady rest C is used to hold the rollers D which are carried in the forked pieces E, these being adjustable by the set screws F. The groove for the copper band and also that for the cartridge case is put in by the tool G held in the casting H. The knurl is done by the small knurl I held in the piece J and secured by the set screw K. While the knurl is in position the undercutting is performed by the two levers L which operate the tools M through slides planed at the desired angle; this can be more clearly seen in the illustration. The end of the shell is faced off with the tool N, and the motion of the tools is derived from the feed handle O. The shell during the operation is held in a split chuck.

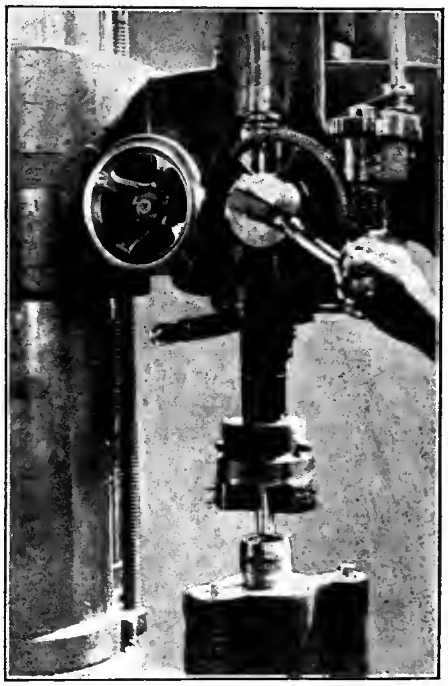

FIG. 4. NOSING OPERATION.

Nosing.

The nosing is performed on an old drilling machine shown in Fig. 4. The work is held in a clamp chuck secured in a fixed position on the drill press table. The cutter head is brought down and the contour of the nose formed by the three forming cutters secured in position in the cutter head.

Boring.

The boring of the shell is accomplished on an old "Gardner" double headed lathe, shown in Fig. 5; the cutting bar being held in position on the tool post of the saddle and a shell placed in the chuck of each head. While the cutting tool is operating on one shell the operator is removing the completed shell from the opposite head and securing another in

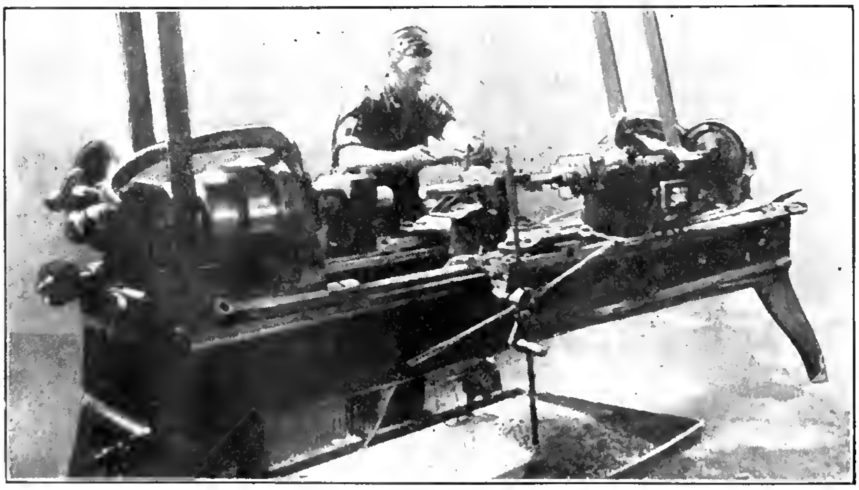

FIG. 5. BORING OPERATION ON DOUBLE HEAD "GARDNER" LATHE.

the chuck in readiness. The cutting operation is therefore almost continuous except for the time taken to change the direction of the traverse of the saddle and in running the latter from one head to the other.

As this particular shell requires a taper of 1/10 of an inch in the length of the bore, the cutting tools in the boring bar are at the top of the bar, and the rear end of each head is elevated sufficiently to give the required taper.

Base of Bore.

Another interesting operation is the forming of the radius at the base of the bore. Owing to the finish required upon these shells it was thought advisable to accomplish this result in the manner shown in Fig. 6. The two machines shown were designed by the superintendent of and built by the A. B. See Elevator Co., Montreal, with the expectations that as the cuttings were free to fall away from the cutting tool, better results would be obtained. The work produced was entirely satisfactory with the exception that the operator might with a little carelessness exert undue pressure upon the feed levers and cause the cutting tool to dig in and tear the stock. The device shown in the sketch, Fig. 7 was designed to offset any such contingency.

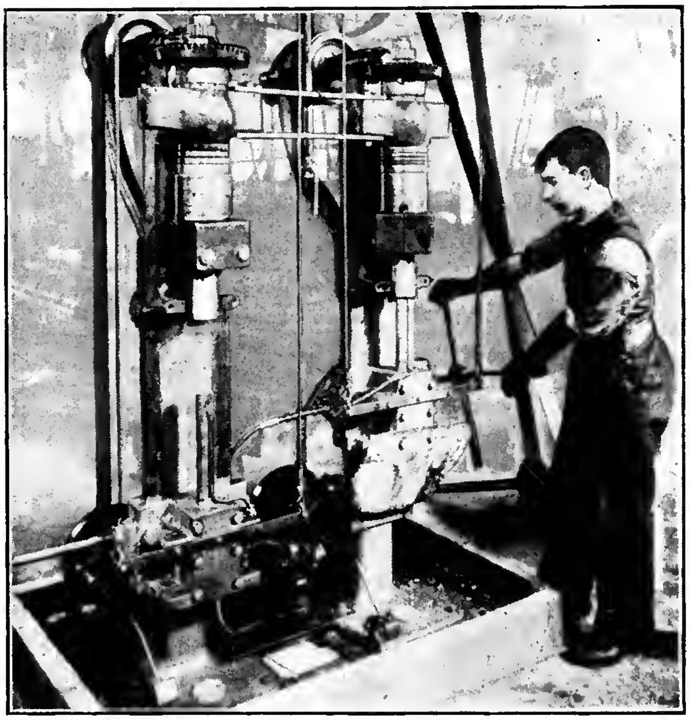

FIG. 6. FORMING BASE OF BORE RADIUS.

Two small cylinders B were bolted to the bottom of the moveable drill table A, and moveable pistons C were placed in these cylinders with an extending piece D. To operate the device, the shell being secured in the chuck shown, the machine is started and the drill raised by hand with the lever H. When about one inch from the bottom, or, when the drill began to cut, the piece E which moved freely on the base of the machine is swung beneath the piece D and the air turned on gradually. The air coming through the port I against the piston C forces the cylinder, and, therefore, the drill up to the work, allowing the chips to fall freely as the operation progresses. A jet of cutting compound is continually forced up alongside the drill, and a pressure of 80 to 100 lbs. per sq. in. is used, giving a raising force of about 700 lbs. to 900 lbs. The pistons used were obtained from the Ford Motor Co.

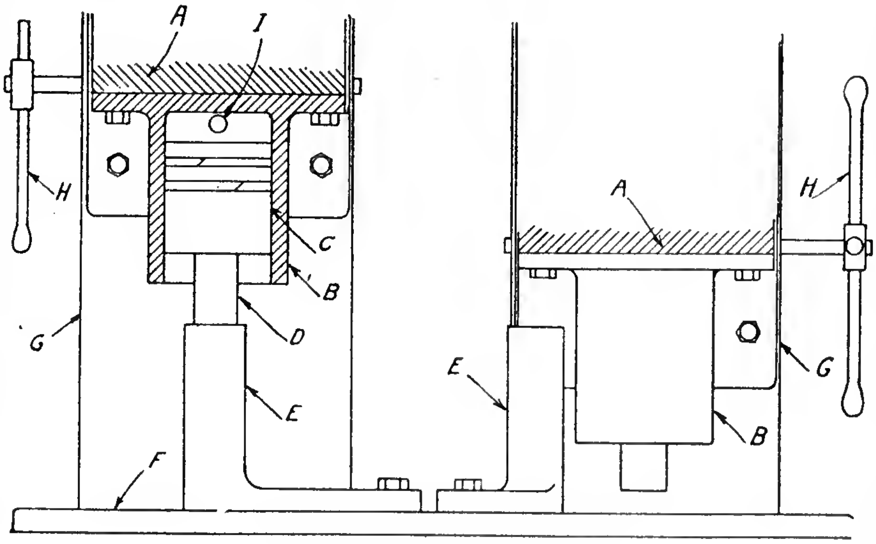

FIG. 7. AIR FEED FOR DRILL.

Cutting Compound.

The cutting compound required in the various operations is forced to the work by means of a small gear pump shown in Fig. 12. The frame A is secured in position on the floor at the rear of the machine so that the pulley B will be below a moveable shaft on the machine around which is placed the driving belt C. The cutting compound drips into a large pan beneath the machine and is there drawn through the hose D by action of the pump and forced up through the hose E to the work.

Heat Treating.

The heat treating process on these shell is in accordance with prepared specifications as follows:

A—Heat slowly in furnace to 850 degrees C., or 1562 F.

B—Hold to this temperature for fifteen minutes.

C—Plunge into water of a temperature of about 62 degrees C. or 142 F.

D—Allow shell to cool in the water.

E—Leave shell in the air until thoroughly dried.

F—Afterwards immerse in a bath of lead at a temperature of about 500 degrees C. or 932 F, and allow to remain for about fifteen minutes.

G—Remove shell from lead bath and allow to cool in the air.

The first heating is done in two Mechanical Engineering Co. furnaces, and the cooling is done in a tank about 4 ft. x 5 ft. x 3 ft. deep. To retain the water at the proper temperature required, some very thoughtful consideration was given and experimenting done, the following procedure being adopted as a result.

Cold water is allowed to enter into the tank through a pipe which has its opening near the bottom of the tank, and the heated water is drawn off from near the surface. To regulate this flow of water, the following interesting and possibly original contrivance is used. An ordinary alarm clock was requisitioned and on the wheel that operates the second-hand, several pieces were arranged so that intermittent contact could be made at intervals of from a few seconds to a minute. When this contact is made, the current is transmitted to coils which, with other arrangements, operate a lever which releases a foot valve and allows a certain amount of heated water to flow from the tank.

As the heating of the shells and the lacquering are done in two separate, temporary buildings, the heated water from the hardening tank is forced through coils placed around the lacquering building for the purpose of keeping it warm in cold weather. The furnace for tem-

pering in the lead bath is shown to the extreme left in Fig. 8.

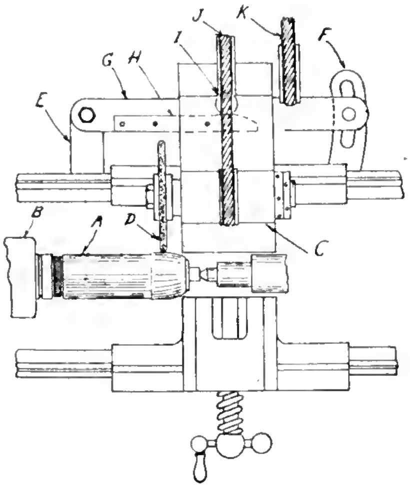

FIG. 9 EXTERNAL GRINDING.

Grinding.

After the hardening it is found necessary to grind both the bore and the outside to bring the shells down to weight also to put the finish on contour of nose. The exterior grinding is done on an old lathe fitted up with taper attachment, Fig. 9. The piece C is secured to the cross-slide of the lathe, and carries the arbor which holds the cutting wheel D which is driven by means of the belt J running over the grooved pulleys, the belt K being driven from a shaft overhead. The cam H which is shaped to suit the form of the nose contour is secured to the bar G which is fitted to the brackets E and F. The roller I which is secured to the base of piece C is held in contact with the cam H by means of the spring on cross-feed spindle.

The internal grinding is accomplished on an old flat turret lathe, the shell A being held in the split chuck B. The adjustable cross slide S is secured to the traverse slide of the turret which is advanced by means of the levers G and the pinion shown which meshes with a rack below the slide. The arbor is driven by means of the groove pulley F. To accommodate the taper of the bore the head is set over the desired amount. Fig. 10 shows a sketch of this device.

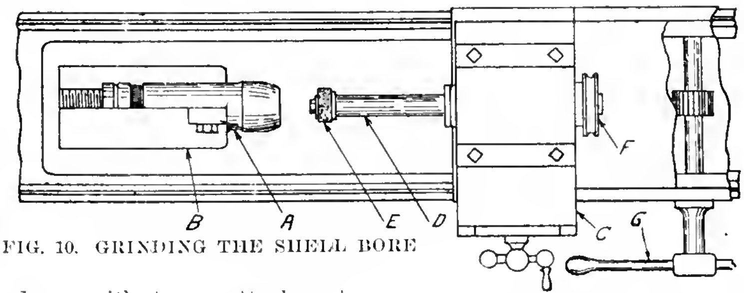

FIG. 10. GRINDING THE SHELL BORE

Lacquering.

A very interesting and original idea for lacquering the exterior of the shells is shown in Fig. 11. The shells have to be coated with a thin even layer of lacquer, and to do this with any degree of satisfaction seemed to be quite a proposition as no ridges or unevenness must appear on the finished shell.

The sketch Fig. 11 shows the method adopted to meet the demand in view. A heavy galvanized iron tank about 2 feet square and 2 feet deep has been constructed and secured in a wooden frame. Half way down the tank B is the partition C which divides the tank into two compartments. From a 2 inch opening in the centre of this partition C, the pipe

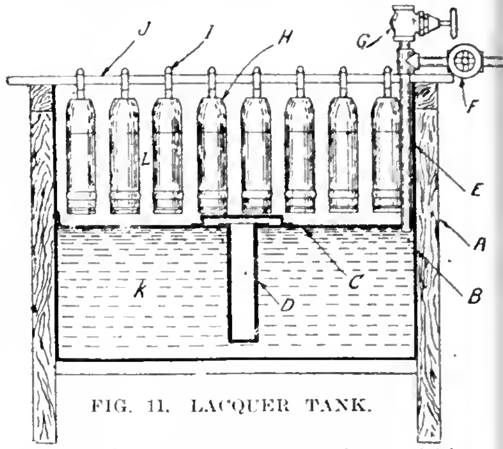

FIG. 11. LACQUER TANK.

or tube D extends downward to within about one inch of the bottom. Down one corner of the tank the air pipe E extends and just enters the bottom compartment. This joint, as well as all the others is made completely air or water tight. The operation of the arrangement is as follows:—

The compartment K is filled with the lacquering fluid and the shells are allowed to hang down supported on a bar which passes through suitable pieces screwed in the nose of each shell. When the shells are placed in position, the valve F, which controls the air from the reservoir, is opened and the air passing through the pipe E to the surface of the liquid forces the lacquer up through the tube D and gradually floods the upper compartment. When the lacquer has

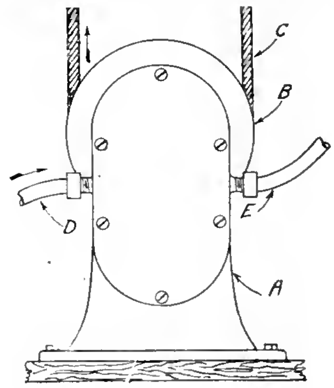

FIG 12. FORCE PUMP.

completely flooded the shells, the valve F is closed and the fluid allowed to remain for a time, or it can be permitted to recede with any degree of rapidity by opening the exhaust valve G, thereby allowing the air to escape and the fluid to re-enter the lower compartment. An uniformly even coating of lacquer on the surface of the shells is the result. The diaphragm M is added to evenly distribute the flow of lacquer.

To prevent the lacquer from adhering to the copper band the latter is coated with a solution which is removed after the shell lacquer has set.

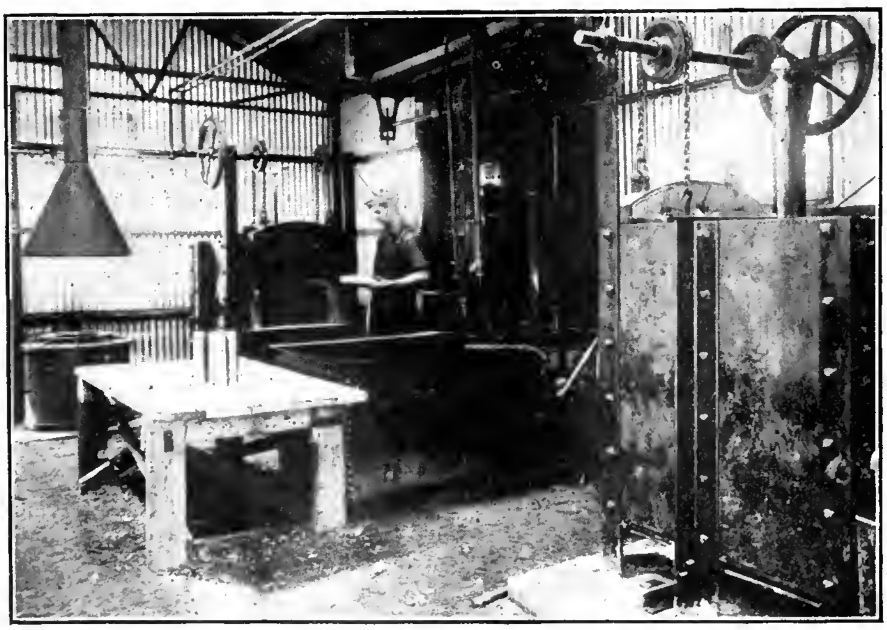

FIG. 8. HEAT TREATING ROOM.

PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

THREE TYPES OF SPRING TESTERS

By G. Edwards

THE springs used for automobile motor valves must be of a comparatively uniform tension in order to give satisfactory service. For this reason, nearly every motor factory has some kind of testing device for testing the power of the springs used. If too stiff or too weak, they must be discarded. Many of the testing devices make use of a standard scale to do the measuring of the spring power.

The one shown in Fig. 1 employs a common counter scale around which a wooden frame has been placed. A screw A and the handwheel B form the means of compressing the spring onto the scale platform. The spring is placed as shown at C and the screw is run down a certain distance. The scale should then "weigh" a certain amount, with an allowance for plus or minus, which has been determined previously and tabulated for the operator's use. The device shown is somewhat slow and cumbersome for any but heavy springs.

That shown in Fig. 2 is easier to use and has a wider range. The wooden fulcrum-bracket bolted to the wall has a number of holes in it for various positions of the compression lever when testing springs of different lengths. The spring to be tested is placed at A and the lever B is brought down as far as the slot in the guide C will allow it to go. The reading is taken from the scale beam as in the previous case. In using this device, care is taken to place the springs under the same spot on the lever, so that the amount of compression and the leverage does not vary to any extent. This device is in use in one of the largest automobile factories in the country.

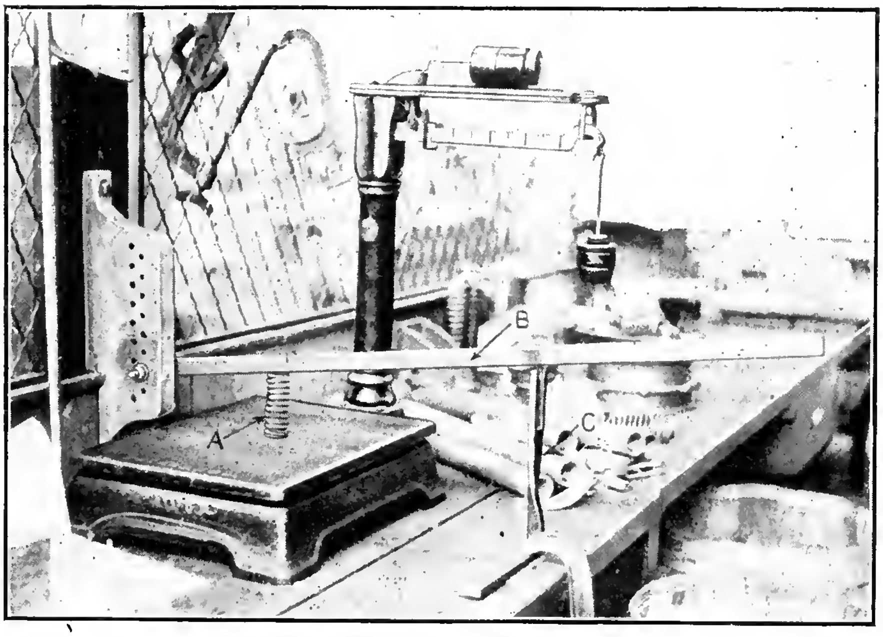

FIG. 2. DEVICE WITH WIDER RANGE.

Another device that is extremely sim-

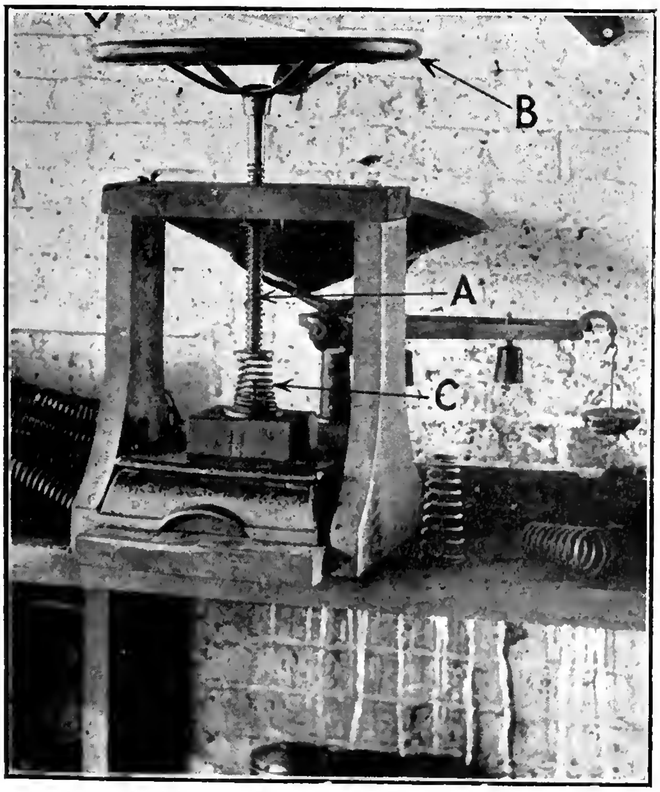

FIG. 1. SCREW-OPERATED SPRING TESTER.

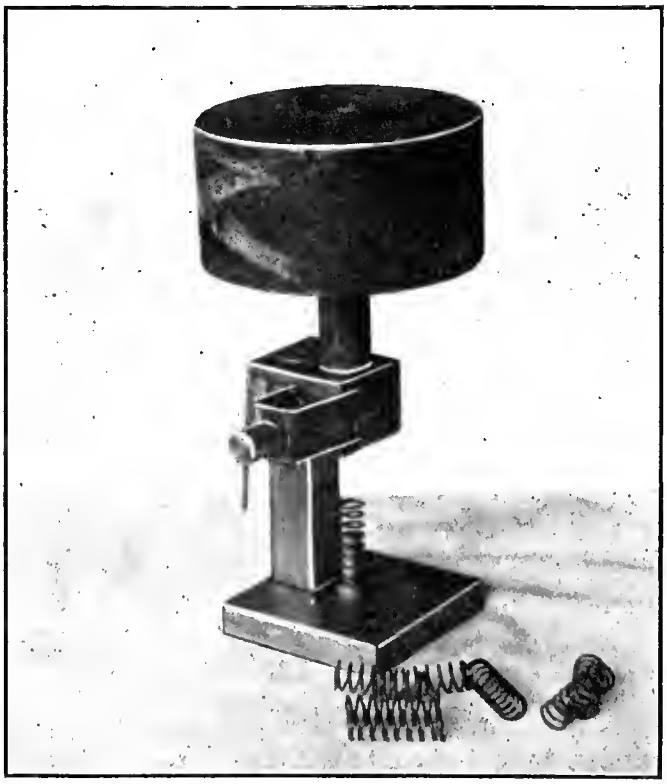

FIG. 3. SIMPLE TESTER.

ple, and does not employ a scale, is shown in Fig. 3. It is used for testing the springs used on a well-known motorcycle. The spring is placed over the locating spring as shown. The weight is then released so that the plunger will come down on top of the spring, the latter having strength enough to just keep the bottom of the plunger from coming in contact with the top of the locating pin. This is adaptable to a large range of work with a few modifications, the principal requirement being suitable weights for various springs. It also has the advantage of being easily made by almost anyone at a slight cost.

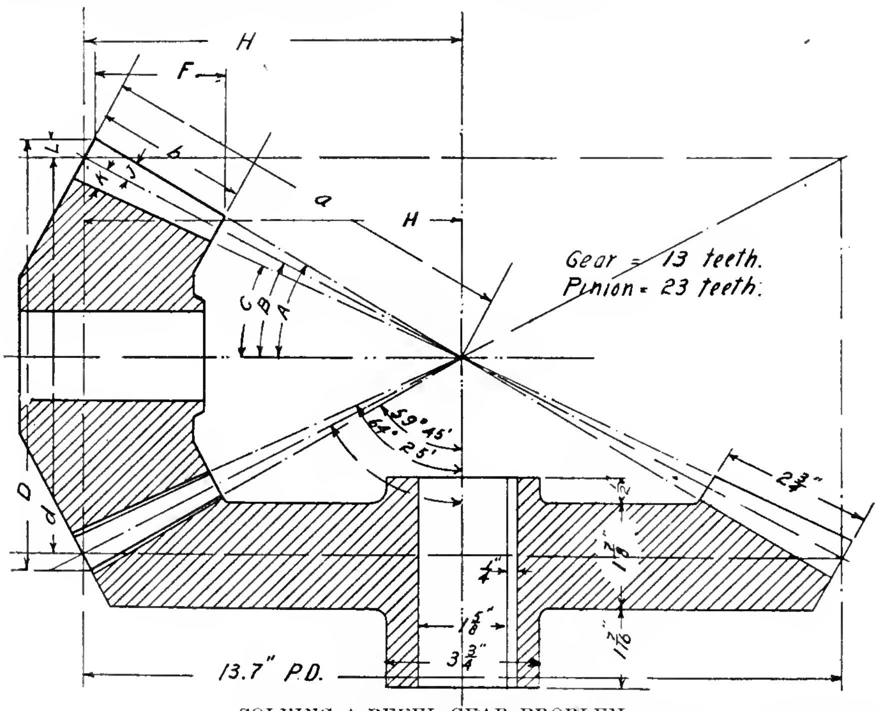
SOLVING A BEVEL GEAR PROBLEM.

By L. E. Gehman.

A jobbing shop received a repair order for a bevel gear and pinion, which called for cut gears and further stated that the original gears had been shipped by express.

The gear arrived in due time but the pinion could not be located. The job was a very urgent one so it was turned over to the draftsman who was informed that he should be able to make a drawing of both gear and pinion from the data which could be secured from the gear.

The gear had 43 teeth and the circular pitch was found to be approximately one inch. The face and cutting angles were next measured by a bevel protractor using the bore of the gear as a finished surface for the protractor. The face angle measured 64° 25′ and the cutting angle 59° 45′, approximately. To get the approximate centre angle one-half of the difference between the cutting and face angles were added to the cutting angle which gave 62° 5′. The outside diameter calipered 14 in., and the pitch diameter 13.7 in.



SOLVING A BEVEL GEAR PROBLEM.
DATA: 43 TEETH, O.D. 14 INS., P.D. 13.7 INS., PITCH 1 IN., CUTTING ANGLE 59° 45′, FACE ANGLE 64° 25′.

The notation and formulas that were used were as follows:

N=Number of teeth in gear.
n=Number of teeth in pinion.
A=Face angle.
B=Centre angle.
D=Outside diameter.
F=Face measured parallel with the axis.
H=Distance from pitch line to the apex parallel with the axis.
a=Distance from the apex of angle to the point of tooth.
b=Length of face.
d=Pitch diameter.
p=Circular pitch.
J=Difference in degrees between the centre angle and face angle.
K=Difference in degrees between the centre angle and cutting angle.
L=Distance from point of tooth to pitch line measured perpendicular to axis.

Calculating for the pitch diameter.

$$d = \frac{NP}{3.1416''} = \frac{43 \times 1}{3.1416''} = 13.687 \text{ in.}$$

which is very near the approximate dimension. In order to figure the angles it was necessary to know the number of teeth in the pinion. Thus using the centre angle 62° 5′ and the formula $\text{Tan.} = \frac{N}{n}$. Solving for the number of teeth in pinion, $n = \frac{N}{\text{Tan. B}} = \frac{43}{1.88734} = 22.7+$.

Assuming that the pinion has 23 teeth and solving for centre angle; $\text{Tan. B} = \frac{43}{23} = \text{Tan. } 1.86957 = 61° \ 51' \ 30''$.

Solving for 22 teeth $\text{Tan. B} = \frac{43}{22} = \text{Tan. } 1.95454 = 62° \ 54' \ 18.8''$. Comparing these results with the approximate centre angle, it is found that the centre angle of the pinion with 22 teeth is 49′ 18″ greater, and the pinion with 23 teeth 13.5″ smaller, than the centre angle, therefore it can be readily seen that the original pinion had 23 teeth.

In calculating the face and cutting angles it is necessary to know the angles J and K and the distance from the apex of the angle to the point of the tooth, parallel with the face of the tooth:—

$$a = \frac{d}{2 \text{ sine B}} = \frac{13.687}{2 \times .88178} = \frac{13.687}{1.76356} = 7.761 \text{ in.}$$

$$\text{Tan. J} = \frac{\text{Addendum}}{a} = \frac{.3183}{7.761} = .04101 = 2° \ 20' \ 54''.$$

$$\text{Tan K} \frac{\text{Dedendum}}{a} = \frac{.3683}{7.761} = .0475 = 2° \ 43'.$$

Face angle $A = B + J = 61° \ 51' \ 30'' + 2° \ 20' \ 54'' = 64° \ 12' \ 24''$.

Cutting angle $C = B - K = 61° \ 51' \ 30'' - 2043' = 59° \ 8' \ 30''$.

The calculated angles and approximate angles are very nearly the same.

The distance H from the pitch line to the apex, parallel with the axis

$$= d \times \frac{\text{cosine B}}{2} = \frac{13.687 \times .53489}{2} = 3.6605.$$

The face measured parallel with the axis $= F = b \times \text{Cos. } A = 2.75 \times \text{Cos. } 64° \ 12' \ 24'' = 2.75 \times .43511 = 1.197''$.

The distance $L = \text{addendum} \times \text{Cos. B} = .3183 \times .47166 = .150$.

Outside dia. $D = d + 2L = 13.687 + .30 = 13.987$.

From the foregoing dimensions a drawing was made, the number of teeth for the pinion being 23, and the pitch diameter twice the distance from the pitch line of the gear to the apex of the angle measured parallel with the axis. The other dimensions being calculated with similar formulæ that were used for the gear and the length of the hub was taken from the machine.

The Coming Foundrymen's Convention and Exhibition

The privilege of spending a week in Atlantic City with its health-bracing and pleasure-giving opportunities may at any time be considered acceptable. There is, therefore, little doubt that, with the added features of a thoroughly installed and attractively displayed exhibition of foundry equipment and supplies, and an unusually high-grade programme of interesting and instructive work-a-day topics aranged for discourse and discussion, foundrymen from all over the United States and Canada will make their presence felt on this occasion in numbers greatly exceeding those of even the most successful of past similar functions.

THE selection of Atlantic City, N.J., as the meeting place for the 1915 Annual Convention of the American Foundrymen's Association and of the American Institute of Metals may justly be stated as a happy choice. The fact also that the Foundry & Machine Co. Exhibition is again found in co-operation leaves nothing to be desired by even the most fastidious or critical. It has been stated—and with more real truth than the mere words express—that the whole eastern section of the country have united as hosts to return the hospitality tendered at similar functions held in recent years in Toronto, Detroit, Cincinnati, Pittsburgh, Buffalo, and Chicago. This is clearly indicated by the fact that the local committee is formed of prominent foundrymen, chosen from the States of Pennsylvania, New Jersey, New York, Connecticut, Rhode Island and Massachusetts.

Its central location and excellent transportation facilities make Atlantic City easily accessible, while its proximity to Philadelphia and New York, in which districts are to be found many large and varied foundry establishments, gives unlimited scope and opportunity to such as may desire to visit and inspect lay-out and operation systems with which they may be unfamiliar, but by which they may profit. At the various sessions of the American Foundrymen's Association and the American Institute of Metals 63 papers and reports will be presented and discussed. In quality and variety the papers are fully equal to those presented at previous meetings and the programmes have been arranged to stimulate the fullest possible discussion.

Both societies will hear the reports of committees that have been at work throughout the year, and it is expected that an unusual volume of valuable foundry information and data will become available through this source. The exhibition will have the advantage of an ideal location which precludes the possibility of overcrowing and inconvenience and affords unusual facilities for the display of working equipment. The entertainment features of the week will be unique and of a character such as can only be found at Atlantic City.

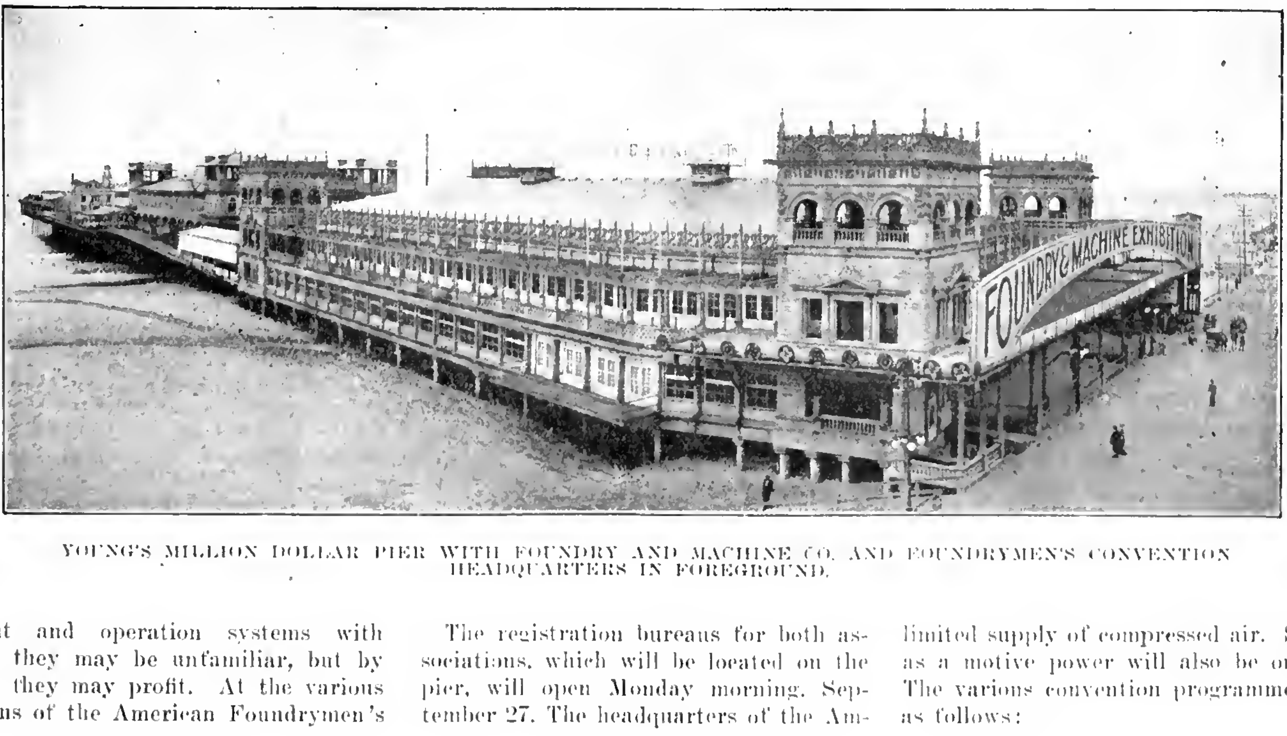
The tenth annual foundry and machine exhibition, under the auspices of the Foundry & Machine Exhibition Co., will open Saturday morning, September 25, and close Friday evening, October 1. The convention proceedings will open at 10 a.m. Tuesday, September 28, with a joint meeting of the American Foundrymen's Association and the American Institute of Metals.

The registration bureaus for both associations, which will be located on the pier, will open Monday morning, September 27. The headquarters of the American Foundrymen's Association and the American Institute of Metals will be at the Hotel Traymore, the latest addition to Atlantic City's galaxy of hostelries. The headquarters for the Machine & Exhibition Co. will be at the Hotel Dennis.

Thursday, September 30, has been set aside as "Philadelphia Day" and an effort will be made to close all Philadelphia foundries on that day to enable the employees to attend the convention and exhibition. The annual joint banquet of the American Foundrymen's Association and the American Institute of Metals will be held Thursday evening, September 30, in order to give as many of the Philadelphia visitors as possible an opportunity to attend.

The American Foundrymen's Association will introduce an innovation by holding its annual business meeting on Wednesday evening, September 29, instead of on Friday morning as heretofore.

Exceptional facilities are, we understand, being provided for operating exhibits. Electric current, both direct and alternating, will be available at various voltages, while exhibitors of pneumatic machinery will have as usual an unlimited supply of compressed air. Steam as a motive power will also be on tap. The various convention programmes are as follows:



YOUNG'S MILLION DOLLAR PIER WITH FOUNDRY AND MACHINE CO. AND FOUNDRYMEN'S CONVENTION HEADQUARTERS IN FOREGROUND.

American Foundrymen's Association

TUESDAY, Sept. 28, 10 a.m. CONVENTION HALL

Joint session, American Foundrymen's Association and American Institute of Metals.

Addresses of welcome and response.

Report of A. F. A. committee on safety, by A. W. Gregg, chairman, Bucyrus Co., South Milwaukee, Wis.

"Tests of Lenses for Foundry Goggles," by F. W. King, Julius King Optical Co., New York. This address will be accompanied by a demonstration of a lens testing machine and a colored spectroscopic test showing scientifically, colors of lenses used in dangerous conditions of light and glare.

Report of A. F. A. committee on industrial education, by Frank M. Leavitt, chairman, University of Chicago, Chicago.

"Functions of Sand Binders," by Henry M. Lane, consulting foundry engineer, Trussed Concrete Bldg., Detroit.

"Notes on Applications and Characteristics of Cores in Modern Molding," by R. A. Bull, Commonwealth Steel Co., Granite City, Ill.

"Molding Sands," by C. P. Karr, associate physicist, Bureau of Standards, Washington, D.C.

Appointments of nominating and resolutions committees.

TUESDAY, SEPT. 28, 2.30 p.m. CONVENTION HALL

Report of A. F. A. committee on specifications for foundry scrap, by S. D. Sleeth, chairman, Westinghouse Air Brake Co., Wilmerding, Pa.

"Patternmaking for Molding Machine Work," of The Fire Engineer, and Harry Y. Carson, Central Foundry Co., New York.

WEDNESDAY, SEPT. 29, 2.30 p.m. CONVENTION HALL

Gray Iron Session

"Pouring Systems for Gray Iron Foundries," by H. Cole Estep, associate editor, The Foundry, Cleveland.

"Fuel Oil Cupolas," by Bradley Stoughton, consulting metallurgical engineer, New York City.

"Inspection of Automobile Castings," by C. B. Wilson, Wilson Foundry & Machine Co., Pontiac, Mich.

"Common Defects in Gray Iron Castings—Their Causes and Remedies Therefor," by Herbert M. Ramp, Elmwood Castings Co., Cincinnati.

Report of A. F. A. committee on specifications for gray iron castings, by W. D. Putnam, chairman, Detroit Testing Laboratory, Detroit.

Report of A. F. A. committee on standard methods for analyzing coke, by H. E. Diller, chairman, General Electric Co., Erie, Pa.

WEDNESDAY, SEPT. 29, 8 p.m., HOTEL TRAYMORE

Annual Business Session

Annual address of the president, R. A. Bull, Commonwealth Steel Co., Granite City, Ill.

Report of the secretary-treasurer, A. O. Backert, Cleveland.

Report of the auditor.

Report of the nominating committee.

Election of officers.

BEACH SCENE, ATLANTIC CITY.

by E. I. Chase, Cadillac Motor Car Co., Detroit.

"Foundations for Jar-Ramming Molding Machines," by E. S. Carman, Osborn Mfg. Co., Cleveland.

"The History and Development of the Molding Machine with Sidelights on Latter-Day Practice," by J. J. Wilson, Cadillac Motor Car Co., Detroit, and A. O. Backert, The Foundry, Cleveland.

"Scientific Management and Its Relation to the Foundry Industry," by H. K. Hathaway, Tabor Mfg. Co., Philadelphia.

"Reclaiming Molding Sand," by W. M. Saunders and H. B. Hanley, Saunders & Franklin, analytical and consulting chemists, Providence, R. I.

"The Relation of the Foundry Foreman to His Employer," by S. V. Blair, Rushville, Ind.

TUESDAY, SEPT. 28, 8 p.m.

Theatre party for members and ladies of the American Foundrymen's Association and the American Institute of Metals.

WEDNESDAY, SEPT. 29, 10 a.m. CONVENTION HALL

"The Modern Foundry Advance," by Dr. Richard Moldenke, consulting metallurgical engineer, Watchung, N.J.

"Manufacture, Constituents and Essentials in the Purchase of Pig Iron for Foundry Use," by Oliver J. Abell, The Iron Age, Chicago.

Report of the A. F. A. committee on costs, by B. D. Fuller, chairman, Westinghouse Electric & Mfg. Co., Cleveland.

Organization in the Foundry of the University of Illinois Shop Laboratories," by R. E. Kennedy and J. H. Hogue, instructors, University of Illinois, Urbana, Ill.

"The Structural or Mechanical Theory of the Effect of Rust on Cast Iron and Wrought Iron or Steel," by R. C. McWane, publisher

THURSDAY, SEPT. 30, 10 a.m. AND 2.30 p.m. CONVENTION HALL AND ANNEX

Steel Sessions

"Dynamic Properties of Steel Employed in the Manufacture of Castings of Various Types," by J. Lloyd Uhler, Union Steel Casting Co., Pittsburgh.

"The Particular Application of the Converter in the Manufacture of Steel Castings," by C. S. Koch, Fort Pitt Steel Casting Co., McKees-port, Pa.

"Notes on Electric Furnace Construction and Operation in the Steel Foundry," by James H. Gray, U. S. Steel Corporation, New York City.

"Open-Hearth Furnace Checker Design," by W. A. Janssen, Bettedorf Co., Davenport, Iowa.

"Causes of Shrinkage Cracks in Steel Castings," by William R. Bossinger, Marion Steam Shovel Co., Marion, O.

Report of A. F. A. committee on specifications for steel castings, by W. C. Hamilton, American Steel Foundries, Granite City, Ill.

Report of A. F. A. committee on steel foundry standards, by Dudley Shoemaker, American Steel Foundries, Indiana Harbor, Ind., and R. A. Bull, Commonwealth Steel Co., Granite City, Ill.

"Notes on Arc Welding," by Robert Kinkead, Lincoln Electric Co., Cleveland.

Malleable Sessions

"Some Remarks Regarding the Permissible Phosphorus Limit in Malleable Iron Castings," by Prof. Enrique Touceda, Rensselaer Polytechnic Institute, Albany, N.Y.

"Standardization of Air Furnace Practice," by A. L. Pollard, Johnston Harvester Co., Batavia, N.Y.

"An Outline to Illustrate the Interdependent Relationship of the Variable Factors in Malleable Iron Practice," by L. E. Gilmore, Baltimore Malleable & Steel Co., Baltimore.

Paper on malleable practice, by J. P. Pero and J. C. Nulsen, Missouri Malleable Iron Co., East St. Louis, Ill.

"Coal—Its Origin and Use in the Air Furnace," by F. Van O'Linda, Consolidation Coal Co., Chicago.

THURSDAY, SEPT. 30, 7 p.m., HOTEL TRAYMORE

Annual banquet.

FRIDAY, OCT. 1, 10 a.m. CONVENTION HALL

Introduction of new officers.
Report of committee on resolutions.
Appointment of standing committees.
Unfinished business.

American Institute of Metals

TUESDAY, SEPT. 28, 10 a.m. CONVENTION HALL

Joint meeting with the American Foundrymen's Association. (For details see A. F. A program.)

TUESDAY, SEPT. 28, 2 p.m. HOTEL TRAYMORE

General Papers

Report of official chemist, by Arthur D. Little, Inc., Boston.

"An Investigation of Fusible Tin Boiler Plugs," by Dr. G. K. Burgess, Bureau of Standards, Washington, D.C.

"The Influence of the Impurities of Spelter on the Cracking of Slush Castings," by Gilbert Rigg, New Jersey Zinc Co., Newark, N.J.

"Cobalt in Non-Ferrous Metals," by H. T. Kalmus, Kalmus, Comstock & Westcott, Cambridge, Mass.

"Furnace Methods for Pure Castings," by F. L. Antisell, Raritan Copper Works, Perth Amboy, N.J.

"Standard Test Specimen of Zinc-Bronze: Cu. 88, Sn. 10, Zn. 2. Relation of the Mechanical Properties to the Microstructure," by Dr. H. S. Rawdon, Bureau of Standards, Washington, D.C.

"Notes on the Copper-Rich Kalchoids," by S. L. Hoyt, University of Minnesota, Minneapolis.

TUESDAY, SEPT. 28, 8 p.m.

Theatre party.

WEDNESDAY, SEPT. 29, 10 a.m. HOTEL TRAYMORE

"The Effect of the Present European War on the Metal Industries," by Thos. F. Wettstein, United Lead Co., New York.

"Sherardizing," by Dr. S. Trood, U. S. Sherardizing Co., New Castle, Pa.

"Electric Furnace for Brass Melting," by F. A. S. Fitzgerald, Fitzgerald Laboratories, Niagara Falls, N.Y.

"Substitutes and Alloys to Take the Place of Platinum," by, W. E. Mowrey, St. Paul, Minn.

"Alloys of Nickel, Chromium and Copper," by David F. McFarland and O. E. Harder, University of Illinois, Urbana, Ill.

WEDNESDAY, SEPT. 29, 2 p.m. HOTEL TRAYMORE

Aluminum and Aluminum Alloys

"Aluminum Die Castings," by Chas. Pack, Doehler Die Casting Co., Brooklyn, N.Y.

"The Manufacture and Use of Alumino-Vanadium," by Wm. W. Clark Seymour Mfg. Co., Seymour, Conn.

"Recent Advances in the Manufacture and Uses of Aluminum," by E. V. Pannell, British Aluminum Co., Toronto, Ont.

"The Welding of Aluminum," by E. V. Pannell, British Aluminum Co., Toronto, Ont.

"Aluminum Bronze Alloys," by W. M. Corse, Titanium Alloy Mfg. Co., Niagara Falls, N.Y.

THURSDAY, SEPT. 30, 10 a.m. HOTEL TRAYMORE

Acid Metals and Bearing Bronzes

"Development of an Acid-Resisting Alloy," by S. W. Parr, University of Illinois, Urbana, Ill.

"Methods of Analysis for Complex Alloys," by S. W. Parr, University of Illinois, Urbana, Ill.

"Effect of Zinc on Copper, Tin, Lead Alloys," by G. H. Clamer, Ajax Metal Co., Philadelphia.

"The Advantages of a Standard Railway Journal," by Russell R. Clark, Pennsylvania Railroad, Pittsburgh.

THURSDAY, SEPT. 30, 2 p.m. HOTEL TRAYMORE

Forging and Rolling Alloys

"Forging Manganese Bronze," by Jesse L. Jones, Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa.

"The Failure of Structural Bronzes," by Dr. P. D. Merica, Bureau of Standards, Washington, D.C.

"Experiences with Brass in Civil Engineering Work," by A. D. Flinn, board of water supply, New York.

"Stellite," by Elwood Haynes, Haynes Stellite Works, Kokomo, Ind.

THURSDAY, SEPT. 30, 7 p.m. HOTEL TRAYMORE

Annual banquet.

Plant Visitation

A large number of important foundries have agreed to throw open their doors to the visitors. Among those may be mentioned the following:—

Southwark Foundry & Machine Co., Philadelphia.

American Engineering Co., Philadelphia.

Girard Iron Works, Philadelphia.

Sheeler-Hemsher Co., Philadelphia.

Eynon-Evans Mfg. Co., Philadelphia.

Baldwin Locomotive Works, Philadelphia.

J. W. Paxson Co., Philadelphia.

Tabor Mfg. Co., Philadelphia.

Isaac A. Shepherd & Co., Philadelphia.

R. D. Wood & Co., Philadelphia.

Wm. Sellers & Co., Inc., Philadelphia.

Ajax Metal Co., Philadelphia.

Thomas Devlin Mfg. Co., Philadelphia.

Niles-Bement-Pond Co., Philadelphia.

American Steel Foundries, Chester, Pa.

Seaboard Steel Casting Co., Chester, Pa.

Worth Bros. Co., Coatesville, Pa.

Baldt Steel Co., New Castle, Del.

The committee in charge of plant visitation is as follows:—

H. W. Brown, chairman, Tabor Mfg. Co., Philadelphia; Harry E. Asbury, Enterprise Mfg. Co., Philadelphia; W. J. Coane, Ajax Metal Co., Philadelphia; Geo. C. Davies, Pilling & Crane Co., Philadelphia; Harry Drinkhouse, Thos. Devlin Mfg. Co., Philadelphia; Thomas Evans, Eynon-Evans Mfg. Co., Philadelphia; Chas. H. Harrar, Midvale Steel Co., Philadelphia; J. S. Hibbs, J. W. Paxson Co., Philadelphia; Wilfred Lewis, Tabor Mfg. Co., Philadelphia; Geo. F. Pettinos, Pettinos Bros., Bethlehem, Pa.; Wm. H. Ridgway, Craig Ridgway & Son Co., Coatesville, Pa.; F. L. Shepherd, I. A. Shepherd Co., Philadelphia; A. G. Warren, J. W. Paxson Co., Philadelphia; and Robert Wetherill, Jr., Robert Wetherill & Co., Chester, Pa.

For the Devotees of Golf

To afford the visiting foundrymen an opportunity to indulge in the favorite pastime of golf, special arrangements have been made with the Country Club of Atlantic City for the use of its course at Northfield, N.J. This feature is in charge of a special committee, whose members will afford the golf devotees every assistance to indulge in this favorite sport. The committee is constituted as follows:—H. M. Bougher, chairman, J. W. Paxson Co., Philadelphia; Peter S. Brauscher, Philadelphia & Reading Railroad, Reading, Pa.; W. J. Coane, Ajax Metal Co., Philadelphia; Wm. J. Devlin, Thomas Devlin Mfg. Co., Philadelphia; Howard Evans, J. W. Paxson Co., Philadelphia; Howard C. Matlack, Marshall, Matlack Co., Philadelphia; H. P. Rebman, American Engineering Co., Philadelphia; Otto Schaum, Schaum & Uhlinger Co., Philadelphia; J. H. Sheeler, Sheeler, Hemsher Co., Philadelphia; W. P. Smith, Wm. Cramp Ship & Engine Building Co., Philadelphia; and E. P. Williams, Baldwin Locomotive Works, Philadelphia.

Local Convention Committee

The local convention committee includes the following:—

Thomas Devlin, chairman, president Thomas Devlin Mfg. Co., Philadelphia; W. H. Bassett, vice-president American Institute of Metals, American Brass Co., Waterbury, Conn.; Henry A. Carpenter, vice-president American Foundrymen's Association, General Fire Extinguisher Co., Providence, R.I.; A. F. Corbin, president New England Foundrymen's Association, Union Mfg. Co., New Britain, Conn.; Alex. T. Drysdale, vice-president American Foundrymen's Association, United States Cast Iron Pipe & Foundry Co., Burlington, N.J.; Stanley G. Flagg, Jr., past president American Foundrymen's Association, Stanley G. Flagg & Co., Philadelphia; H. W. Gillett, vice-president American Institute of Metals, Ithaca, N.Y.; Dr. Richard Moldenke, past secretary, American Foundrymen's Association, Watchung, N.J.; Geo. C. Stone, vice-president American Institute of Metals, New Jersey Zinc Co., New York; A. W. Walker, past president, American Foundrymen's Association, Walker & Pratt Mfg. Co., Boston, and Walter Wood, vice-president American Foundrymen's Association, R. D. Wood & Co., Philadelphia.

List of Exhibitors.

Ajax Metal Co., Philadelphia, Pa.
Arcade Mfg. Co., Freeport, Ill.
E. C. Atkins & Co., Indianapolis, Ind.
Ayer & Lord Tie Co., Chicago.
Berkshire Mfg. Co., Cleveland, O.
Chas. H. Besly & Co., Chicago.
S. Birkenstein & Sons, Chicago.
Blystone Mfg. Co., Cambridge Springs, Pa.
Brass World and Plater's Guide, New York City.
Brown Specialty Machinery Co., Chicago.
Buch Foundry Equipment Co., Bridgeport, Pa.
Buckeye Products Co., Cincinnati, O.
Carborundum Co., Niagara Falls, N.Y.
Cataract Refining & Mfg. Co., Buffalo, N.Y.
Charles J. Clark, Chicago.
Clark Foundry Co., Rumford, Me.
Clearfield Machine Shops, Clearfield, Pa.
Cleveland Automatic Machine Co., Cleveland, O.
Cleveland Pneumatic Tool Co., Cleveland, O.
Clipper Belt Lacer Co., Grand Rapids, Mich.
Geo. P. Clark Co., Windsor Locks, Conn.
Joseph Dixon Crucible Co., Jersey City, N.J.
Electric Controller & Mfg. Co., New York.
Felt & Tarrant Mfg. Co., Chicago.
Factory (A. W. Shaw Publishing Co.), Chicago.
Gardner Machine Co., Beloit, Wis.
General Electric Co., Schenectady, N.Y.
Goldschmidt Thermit Co., New York.
Graceton Coke Co., Graceton, Pa.
Great Western Mfg. Co., Leavenworth, Kansas.
F. A. Hardy & Co, New York.
Hayward Co., New York.
Herman Pneumatic Machine Co., Zelienople, Pa.
The Herold Bros. Co., Cleveland, O.
Hill & Griffith Co., Cincinnati, O.
Hunter Saw & Machine Co., Pittsburgh, Pa.
Ingersoll-Rand Co., New York.
International Molding Machine Co., Chicago.
International Steam Pump Co., New York.
The Iron Age, New York.
Iron Tradesman, Atlanta, Ga.
Jennison-Wright Co., Toledo, O.
Julius King Optical Co., Chicago.
Landis Tool Co., Waynesboro, Pa.
Lehigh Coke Co., South Bethlehem, Pa.
Lincoln Electric Co., Cleveland, O.
David Lupton's Sons Co., Philadelphia, Pa.
J. S. McCormick Co., Pittsburgh, Pa.
McCrosky-Reamer Co., Meadville, Pa.
MacLean Publishing Co., Toronto, Ont.
The Macleod Co., Cincinnati, O.
Mahr Mfg. Co., Minneapolis, Minn.
Malleable Iron Fittings Co., Branford, Conn.
Midland Machine Co., Detroit, Mich.
Monarch Engineering & Mfg. Co., Baltimore, Md.
Mott Sand Blast Mfg. Co., Chicago.
E. H. Mumford Co., Elizabeth, N.J.
Mumford Molding Machine Co., Chicago.

Steel Ingots for Guns.—Prof. J. O. Arnold, of Sheffield University, at the Royal Institution, said that the managing director of Krupps told him that they were making steel ingots weighing 110 tons for guns by the crucible process evolved 175 years ago by an Englishman—Benjamin Huntsman. Neither the Germans nor the Americans could produce the Sheffield white crucible, however. That was a secret handed down from father to son in Sheffield. In the North of England they were making ingots weighing 150 tons, and there were 12,000-ton presses squeezing out armor plate like cheese.

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

HIGH SPEED HACK SAW MACHINE

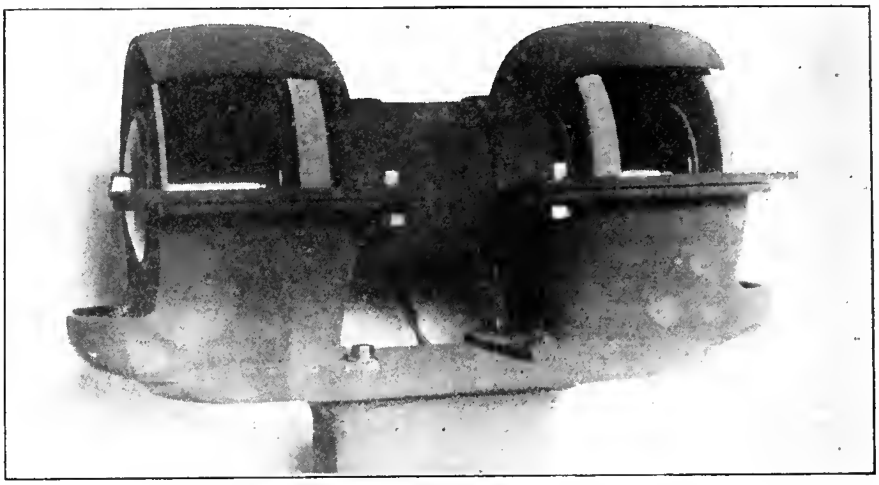
THERE has recently been put upon the market the high speed hack saw machine here described and illustrated. It has been developed by the Massachusetts Saw Works, Springfield, Mass., and embodies among other features a shock absorber, extension frame, swivel-jaw vise, and an automatic patent lift.

The machine is particularly designed for the rapid cutting of metals in sizes up to 9 by 9 inches, and is heavily constructed with all intricate mechanism eliminated as far as possible. The unit is set low on a solid foundation with wide-spread legs to give the maximum rigidity and steadiness, while a large pan for suds surrounds the bed and contains a 9-gal. tank divided and screened for chips. The tank, pan, bed and legs together form a single casting. The power section or head of the machine swings on a shaft centre, an arrangement which is relied upon to give a steady, silent motion with little wear and to secure a full length stroke of the blade at any angle. The bearings have, as far as possible, been made heavy and wide throughout the machine, and readily accessible arrangements for taking up the wear are provided.

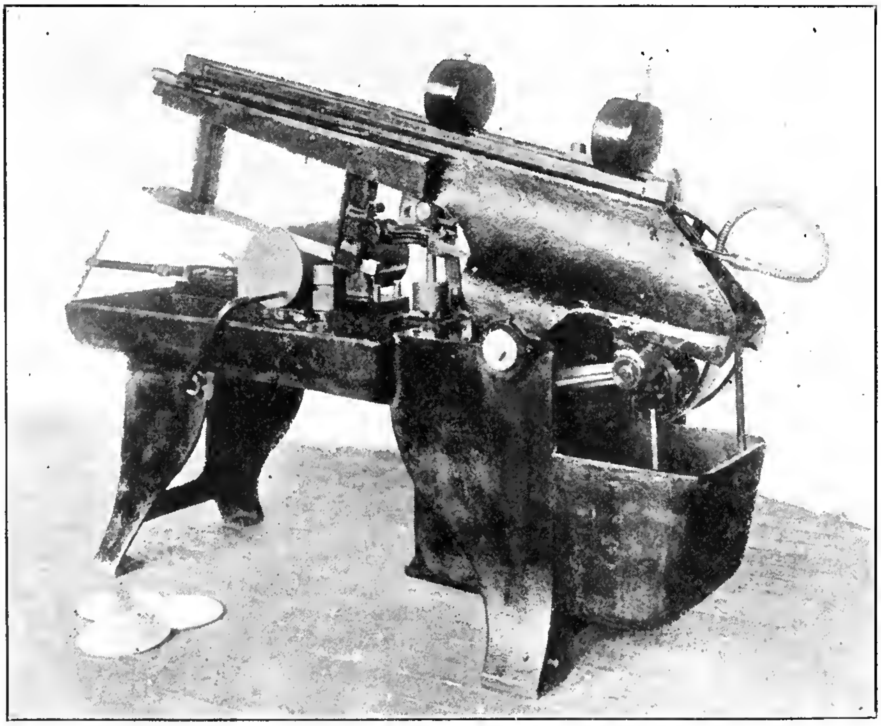
Two speeds for the saw blade are provided, the change being made by shifting the starting lever on the back of the machine to engage one or the other of the pulleys mounted on the driving shaft.

The descent of the blade is lever controlled and cushioned, while the vertical movement may be stopped at any point, a shock absorbing device permitting it to engage the material gently. On completion of the cut the machine stops, an oil dashpot under the bed acting as a cushion.

The extension frame will hold blades ranging from 12 to 17 in. in length. To vary the length of the frame, it is simply necessary to push a button which releases the locking mechanism, and pull the frame out as far as desired, after which the blade is inserted without other manipulation. Means are provided for lifting the saw clear of the work on the idle or non-cutting stroke.



SPECIAL PATTERN SHOP GRINDING MACHINE.



HIGH SPEED HACK SAW MACHINE.

The patent swivel-jaw vise has a capacity of 9 in. and the rear jaw may be set at any angle up to 45 deg. in either direction. The front or sliding jaw will adjust itself to the angle of the fixed jaw or to an irregular surface. If desired, the vise may be advanced along the table of the machine to double the capacity of the blades on small work or it can be removed entirely and bolts and clamps substituted when necessary.

A rotary pump with a double check valve delivers cutting compound to the blade as soon as the machine starts. The lubricating system has received particular attention and includes oil cups, waste boxes and holes for every bearing or working point.

The principal dimensions of the machine are as follows: Capacity for cutting stock up to 9 inches square; size of blades, from 12 to 17 inches in length; size of pulleys, 16 inches in diameter by 3 inches face width; floor space occupied, 5 feet 3 inches by 2 feet 8 inches; and weight of machine 845 pounds.

PATTERN SHOP GRINDING MACHINE.

THIS new tool grinder, which is a product of the Forbes & Myers Co., Worcester, Mass., has been designed to meet the needs of pattern-making and other

wood-working shops. It is made in both the bench and floor types, the photograph showing the grinder and top of stand of the floor type machine.

The regular equipment of wheels consists of one 10 in. x 1 in. with flat face for grinding chisels and other straight edge tools, also three round face wheels 10 in. in diameter by 1 in., ½ in., and ¼ in. respectively in thickness, for grinding gouges and special cutters. Other shapes of wheels can also be furnished.

The spindles are ¾ in. in diameter and ample space is allowed between the wheels. The guards are of heavy malleable iron, and the tool rests are adjustable in two directions. High grade ball bearings are used, these being thoroughly protected from dirt and grit by double grooved covers, and packed in grease.

The motor is of the squirrel cage induction type and can be supplied for two or three-phase alternating current circuits only. The capacity of the motor which is fully inclosed as a protection against dirt and mechanical injury, is ½ h.p. Frequencies of 25, 50 or 60 cycles can be used, the speed being 1,500 r.p.m. on the 25 and 50-cycle circuits, and 1,800 r.p.m. with the 60-cycle current.

MACHINE FOR SPRAYING SHRAPNEL SHELLS

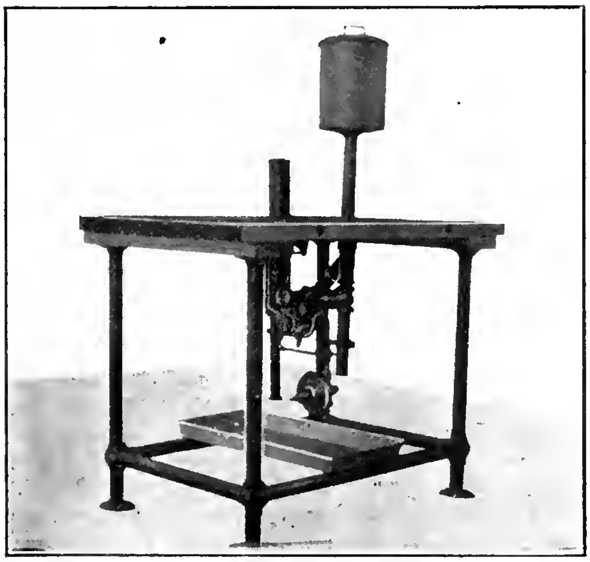
TO coat the inside of shells, or for that matter any relatively inaccessible surface, with an asphaltum paint or anti-corrosion material, and to do the work rapidly, uniformly, and without waste of the coating compound, the Spray Engineering Co., Boston, Mass., has developed an interesting machine.

It looks not unlike a strongly built table with a circular recess in the top. The operator inverts a shell over the recess, pushes it down an inch or so into the latter, lifts it from the table, and the operation is completed, the shell having received its coating. He is then ready to repeat the operation with another shell. As the period covered in thus spraying a shell is 2 sec., or at the rate of 30 per minute, the capacity of the machine for coating is placed at 1,500 per hour.

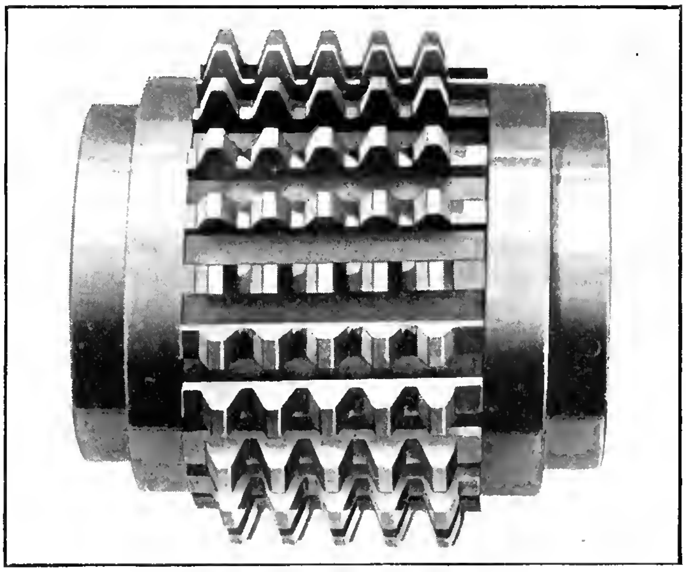
The act of pushing the shell downward admits a supply of compressed air to a definite quantity of the protective liquid, which is driven through a spraying nozzle. The apparatus is supported under the table top. It includes what is substantially a three-way valve which holds the protective liquid and which opens the channel between the compressed air supply and the nozzle when the shell is down, so to speak, and which receives the measured amount of liquid for the next shell when the pressure of the operator's hand is removed: that is, when the coated shell is removed. The fact that only the desired amount of liquid is admitted each time is a particular feature and application has been made for a patent covering the device. The working parts are counterbalanced as far as possible so that a minimum pressure will suffice to push the shell to the spraying position. It is obvious the machine is likely to find fields of usefulness outside of that for which it has been brought into being.

The height of the spray head is adjusted to coat the entire inner surface of the shell and the extent of this surface with the prescribed thickness of the paint film, sometimes 0.00025 in., gives some measure of the requirements. The amount of paint is regulated by what corresponds to a plunger which may be screwed in or out, decreasing or increasing the contents of the measuring chamber. For a given size of shell and a given paint and thickness of film, it is found that one setting of the measuring device suffices to insure that not only is sufficient paint sprayed upon the shell surface but there is no excess which has to be disposed of. The machine thus aims at a maximum economy of the protecting compound beside allowing for high working speed.

It is expected that the fundamental elements of the machine, the use of the spray head, and of the scheme for automatically measuring out the quantity of material to be sprayed, may have applications apart from war munitions. However, at this writing the company is engaged on working out details for utilizing the machine for spraying the small annular passage in the timing device or nose portion of the shell. This passage, which receives the time fuse, is small and somewhat inaccessible, and to swab the passage with a hand brush consumes too much time in view of the demands for high quantity production. It appears that in spite of the fact that the timing parts of the shell are of brass, the powder has a corroding influence, which fact makes it desirable to poteet the brass work.



SHRAPNEL SHELL SPRAYING APPARATUS.



LEES-BRADNER HYPERBOLOID HOB.

HOB OR GENERATING TOOL

THE accompanying illustration shows the type of generating tool, commonly called a hob, as produced by the Lees-Bradner Co., Cleveland, Ohio.

Technical papers for years past have been full of arguments pro and con on the hobbing process, or as it should be correctly termed, the generating process. Much of the criticism, justly made, as far as practice was concerned, was due both to practice and theory—the errors being occasioned almost universally by

error in the hob, or due to the design of the machine employed.

The cardinal principles of gear cutting cannot be overlooked simply because the gears are hobbed. In other words, gears must be concentric, and the sides of the teeth must be uniform. These two features have been most criticized from the fact that the teeth have not been uniform due to the hob, or the gears have not been concentric, due to the design of the tool on which the hob was used.

The Lees-Bradner Co., who are pioneers in the art of hobbing gears, have made a careful study of this subject for a number of years, as a result of which the "hyperboloid" hob shown in the illustration has been developed. The theoretical considerations calling for the use of a hob of this form are that the cutting edges of each series of teeth must enter and depart simultaneously on a theoretical line, which has been designated the "generating plane."

It will be apparent in a hob of the solid cylindrical type, which is fluted at right angles to the lead, that the row of teeth which is generating presents an elliptical outline to the gear being cut. In addition, the helical flute presents a warped surface with one end of the flute stubbed and the other end raked, as far as the generating plane is concerned. This can be readily seen if the fact is grasped that a section taken through a cylinder at right angles to the axis is a circle, that a section taken through a cylinder parallel to the axis is a rectangle, while a section taken through a cylinder at an angle to the axis is an ellipse.

As a result, it will be evident that with the hob set at its working angle, an elliptical outline will be presented to the work. Therefore, to obtain a hob that will produce a rectangle under these conditions, it is necessary for the tool to be of hyperboloid outline. The hyperboloid hob shown is made up of a series of high-speed steel racks which are ground for lead, side relief, top relief, and to provide sharp cutting edges. The racks can be renewed as they become worn out, and as the housing is hardened and the bore ground to a plug gauge fit, it is likely to last indefinitely.

TO DEVELOP MUNITIONS OUTPUT IN CANADA

STEPS were taken by the Canadian Government on Sept. 13 to organize an effective and energetic coalition of the representatives of industry and finance with the Militia Department towards the production in Canadian factories of war munitions in the largest possible quantities and with the greatest possible expedition.

Representatives of finance and industry to the number of a hundred or more were summoned to Ottawa by Sir Robert Borden and Sir Sam Hughes for a conference as to how best to finance and produce the ammunition, ordnance and supplies of all kinds of war munitions which Canada can furnish to meet the pressing needs of Great Britain and her allies.

Devising Ways and Means

To-day's conference was with a view to taking counsel together as to the possibilities of manufacture, the methods of financing, etc. The conference was, of course, of a confidential character, but the discussion emphasized the fact that through adequate co-operation and organization Canada can and will do much more towards meeting the most urgent needs of the allies at the present time—namely, the furnishing of the engines of war, including the manufacture of field guns.

Permanent Advisory Board

A sub-committee of those attending the conference was appointed, under the chairmanship of Sir John Gibson, and this committee met for three hours and carefully considered the whole situation. As a result a report will be presented a little later to the Minister of Militia, embodying some suggestions as to organization and methods of distributing and filling orders, and in regard to proposals for the manufacture of ordnance of various kinds. The sub-committee adjourned, to meet at the call of the chairman, and it will constitute a permanent advisory body to the Government.

The conference, which was held in the room of the Militia Council, was presided over by Sir Sam Hughes, who gave to those present a full and frank statement of the needs and opportunities of the situation.

Sir Robert Borden also spoke at some length, giving the conclusions reached from his conferences with the War Office and Munitions Department in London.

Personnel of Conference

The personnel of the conference included the following: Hon. Major-General Sir Sam Hughes, President; Sir Robert Borden, Brig.-Gen. Bertram, Sir John Gibson, J. F. Taylor and Arch. Stewart, Algoma Steel Company, Sault Ste. Marie; Col. Noel Marshall; John Carew, M.P.P., Lindsay; Col. Woods, Ottawa; Col. Wanklyn, C.P.R., Montreal; James Young of the John Bertram & Sons' Co.; P. L. Findlay, Montreal; H. Bertram, Dundas; H. M. Asling, Polson Iron Works, Toronto; M. C. Ellis, Toronto; R. Gilmour, Ottawa; W. R. Angus, Canada Star Foundry, Montreal; H. D. Pickett, Moose Jaw; G. H. Duggan, Dominion Bridge Co., Montreal; G. H. Chaplin, St. Catharines; Brig.-Gen. F. S. Meighen, Montreal; Col. C. W. Watts, Canadian General Electric Co.; Major R. W. Leonard, F. P. Jones, Sir. W. Mackenzie, Edward Gurney, Toronto; S. Major, Hamilton; H. H. Vaughan, Montreal Ammunition Co., Montreal; E. Hay, General Manager Imperial Bank of Canada, Toronto; B. B. Stevenson, Quebec Bank, Montreal; Sir William Ince, Union Bank, Quebec; G. H. Balfour, General Manager Union Bank of Canada, Winnipeg; C. P. Schofield, General Manager Standard Bank of Canada, Toronto; F. L. Pease, General Manager, Royal Bank of Canada, Montreal; Sir Herbert Holt, President Royal Bank of Canada, Montreal; Sir Edmund Walker, President Canadian Bank of Commerce, Toronto; John Aird, General Manager Canadian Bank of Commerce, Toronto; H. A. Richardson, General Manager Bank of Nova Scotia, Toronto; K. W. Blackwell, Vice-President Merchants Bank of Canada, Montreal; Hector McInnes, K.C., Halifax, N.S.; Sir Lyman M. Jones, Toronto; Senator Edwards, Ottawa; H. W. Wheatley, Can. Loco. Works, Kingston; W. D. Robb, G. T. R., Montreal; T. J. Dillon, Welland; A. R. Goldie, Galt; J. P. McNaughton, Sydney; W. Inglis, Toronto; Rev. F. W. Squire, Ottawa; D. Lemon, Montreal; J. A. Vaillancourt, Montreal; John P. Dunn, Prescott Emery Wheel Co., Prescott; Sir Henry M. Pellatt, Toronto; P. C. Brooks, Can. Fairbanks-Morse Co., Toronto; C. G. Drinkwater, Can. Fairbanks-Morse Co., Montreal; E. W. Gilman, Ingersoll Rand Co., Sherbrooke; E. S. Winstow; Col. Fred Nicholls, Toronto; M. L. Davis, Standard Chemical Co., Toronto; Douglas C. Ridout, President Toronto Furniture Co., Toronto; Robert Hobson, Steel Company of Canada, Hamilton; George Burn, President Canadian Bankers' Association; A. D. Braithwaite, Bank of Montreal; E. F. Hebden, Merchants Bank, Montreal; H. B. Mackenzie, Bank of British North America, Montreal; H. J. Myler, Hamilton; Warren Y. Soper, Ottawa Car Works.

Sub-Committee on Ordnance

The sub-committee appointed to report on an increase in munitions, and particularly to inquire into the feasibility of Canada, in addition to making shells, going into the manufacture of heavy guns and ordnance, is as follows:

Sir John Gibson, the members of the Shell Committee, Col. Nicholls, Toronto; W. D. Robb of the Grand Trunk; Hector McInnes, Halifax; F. L. Wanklyn, C. P. R.; Sir Lyman Jones, Sir William Mackenzie, Toronto; Senator Edwards, Ottawa; K. W. Blackwell, Montreal; James Young, Dundas; G. H. Duggan, Montreal; George Burn, Ottawa; J. Chaplin, St. Catharines, and P. L. Miller of the Canadian Vickers Co.

THE FUTURE OF DEMOCRATIC LABOR

When Bellamy wrote that noteworthy book, "Looking Backward," he did not enter into specific details regarding previous conditions, the climax of which was characterized as a world cataclysm. Social developments in Britain previous to this war were proceeding at a rapid pace to a point where opposition of a decided nature was beginning to show itself. A complete permeation of society with democratic ideas, such as are evidenced by state insurance and employment bureaus might probably have resulted in that social upheaval or disruption in the mysteries of which Bellamy shrouded his imaginary transformation of human society. The scheme by which each member of society was allowed to pursue the active duties which were most congenial to the individual and of corresponding value to the community, in return for which he was entitled to a sufficiency of life's necessities and luxuries, has had, and always will have a great attraction for those whose effort is to secure for labor an adequate reward.

Attempts have been made on different occasions to put into practice some of the basic principles of socialism. Some have succeeded and some have failed; the failures being partly due to the fact that man is occasionally possessed of ambition, and the "bacillus ambitionis" has decided objection to being levelled down or otherwise restrained from exerting its expansive properties.

Students of current events may perhaps perceive in the present turmoil of affairs, a change in man's attitude to man, the ultimate result of which will be a considerable advance toward that Utopian existence so ardently advocated in some quarters. Germany, as a nation, seems to have had some idea of developing the world on Bellamistic lines, but made the unfortunate mistake of trying to force matters. Her loss will, however, prove to be the world's gain first, and her own gain ultimately.

The great change in society's attitude toward labor is at the present time more strongly evidenced in Europe than in Canada. This is so because of the more acute conditions prevailing there.

Its most important feature is, perhaps, the acknowledgement by society of its absolute dependence on labor, and by society is meant the nation, government, titled and untitled persons, the rich and the poor. When lords and similarly classed individuals get into overalls and do their bit voluntarily because they realize the necessity, it ill befits labor to counteract these additional efforts by wilful abstinence from production.

Canadian labor has shown and will continue to show a patriotic enthusiasm in production, which one would fain believe to be universal in the Motherland. Canadian manufacturers have shown an appreciation of labor's efforts, such as never would have occurred in times of peace, and the chief interest of labor should now be how to maintain that appreciation when peace returns.

It is quite obvious that if the majority of men receive adequate remuneration, they will give adequate service, willingly and continuously, always provided, of course, that not more than adequate profit is acquired through their labor. The experience of the British Government in organizing controlled shops may ultimately be incorporated in legislative efforts which may be epoch-marking, and the indiscriminate mixing of all grades of society which has taken place with the growth of Britain's armies will have an undoubted influence on the future reception of democratic legislation.

While Canada as a younger and distant nation has had to form her national character alone and unaided, the centuries old experience of the Motherland has always been available, and in the readjustment of affairs in the days yet to come, the development of advanced democratic views in all branches of Canadian life, will be not the least interesting result of that spirit of co-operation now so happily existing between employees and employers.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents

Montreal, Que., Sept. 13, 1915.—The firm trend and noticeable improvement in the industrial situation is undoubtedly due to the steady demand from Britain and her allies for munitions and supplies, incidental and necessary to the maintenance of men and equipment for the successful prosecution of the war. That still greater activity is about to develop is shown by the meeting held in Ottawa to-day, at which a number of our leading financiers and executive heads of manufacturing establishments discussed ways and means whereby both sections may co-operate with the Government to increase production of war necessities.

It is expected that orders for shells in still larger quantities will soon be placed. One large firm in Montreal, in discussing this feature, said that they had received word from Ottawa, the tone of which was highly optimistic. Some manufacturers are now installing extra heavy tools for the production of 4.5 shells, the expectation being that the near future may warrant them doing so when still larger size shells will be called for.

Many inquiries have been received, and in some cases orders have been placed for lathes of 24 in., 26 in., and even larger sizes, for the production of 6-in. and 9-in. shells for the French and Russian War Offices.

Steel.

The abnormal demand for billets and bars used in the production of various types of shells and component parts keeps the steel mills constantly going at about 100 per cent. capacity, and with orders on their books which cannot be filled for many months to come. If a supply of larger shells is demanded, and this seems more than likely, it will call for increased activity on the part of our steel producers to keep up the required supply of raw material.

Pig Iron

The pig iron market shows little activity, but quotations on the various grades remain firm.

Machine Tools and Supplies

Inquiries for machine tools continue to come in, but in a great number of cases it is almost impossible to have delivery within a period of six or eight months, especially on machines employed in the production of 3.3 and 4.5 shells. The feeling is growing that machine tool builders will soon have to meet the demand for a larger and heavier product to meet the requirements of a correspondingly larger and heavier type of shell.

The demand for supplies, both for the smaller and larger tools, is daily growing greater, and there is little doubt that the near future will see further development in that direction.

Metals.

Very little change is shown in the metal quotations for the week, and as many of the leading manufacturers of brass and copper products are withholding their price lists, it leaves the tone of the market a little uncertain.

Scrap.

The tendency is upward in scrap metals, a slight increase being noticeable in the majority of quotations.

Toronto, Ont, Sept. 14.—Industrial conditions are much the same as last week, but a better feeling prevails in business circles due to the splendid crops in the West, a large yield being now assured. This will stimulate domestic trade, which has been comparatively quiet for several months, but has lately been showing distinct signs of improving. The expansion in the export trade of the country has had much to do with this, as has also the return of a more confident spirit in business circles. There is every reason to expect further heavy orders for war supplies being placed with Canadian manufacturers. It is understood that Premier Borden has been given the fullest assurance by the British Government that for all supplies that have to be procured outside the United Kingdom Canada's resources would be utilized to the fullest extent.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Steel Market.

Reports of the financial condition of the principal steel companies in Canada are exceedingly satisfactory. Conditions in the trade continue to improve, due principally to increasing export business and demand for rounds and forgings for shells. In this regard it is announced that as a result of Mr. Thomas' visit further orders approximating fifty million dollars will be placed in Canada for making munitions. It is further stated that it is the desire of the authorities to place such orders where they can be most speedily and economically filled. Prices on bars, plates, and shapes are very firm, but unchanged. Billets have again advanced, "Bessemer" being now quoted at $24, open hearth $24.50, and forging billets $32, all f.o.b. Pittsburgh. Wire rods have also advanced, and are now quoted at $29 Pittsburgh. With regard to semi-finished steel, it is reported from Philadelphia that competition has appeared in that market from Canadian mills for various sizes of billets and blooms. No sales, however, have been heard of.

There is no abatement in the demand in the United States for open-hearth steel products, much of it being for war munitions. Pittsburgh mills report that they are operating to capacity, and unable to catch up with deliveries. The new demand for plates, shapes, and bars, particularly the latter, is very urgent, and the mills are filled up for weeks ahead. The scarcity of steel-making metal, particularly ferro-manganese, is gradually becoming more acute, and prices for ferro-alloys are advancing. Ferro-manganese is now being quoted at $100 to $110 per ton f.o.b. seaboard. Prices of steel bars have advanced to $1.35 Pittsburgh.

The galvanized sheet market is firming up slightly because of the uncertainty in the price of spelter. The advancing tendency in price of spelter has reduced production of sheets somewhat, as makers do not want to accumulate stocks until the spelter situation clears up. The high-speed tool steel situation does not improve, and prices have an advancing tendency.

Pig Iron

The situation is much the same as last week, and there is a good demand for steel-making pig iron. Prices for American brands are firmer, and grey forge has advanced to $14.70 Pittsburgh. Domestic pig irons are unchanged.

Machine Tools

There is practically no change in the situation as regards machine tools, and no developments have as yet to be noted. The report that further large orders for shells will be distributed may result in further buying of machine tools, although it is highly probable that plants already well equipped will be favored with the greater part of this business. There is every possibility, however, that even these concerns will have to install

more equipment. Inquiries for new machines have fallen off, but there is still a good demand for second-hand equipment. Deliveries in new tools are still very backward and prices have a higher tendency.

Supplies.

Business in machine shop supplies continues brisk, and prices all round are very firm. All American lathe chucks have advanced. "Independent" chucks, which were 20 per cent. off, are now net list, and 12 per cent., has been added to geared scroll chucks. Prices of leather belting are very firm, as there is a great scarcity of hides and a big demand for leather. Half-and-half solder is a little lower, and is now quoted at 24c per pound. The linseed oil market is steadier, but business is very dull. Prices have declined 2c, and oil is now quoted at 63c for raw and 66c for boiled oil per gallon.

Scrap Metals

The scrap metal is firmer, particularly for copper and brass scrap, which have advanced. Heavy lead is also little higher, being quoted at 5c per pound, but tea lead is unchanged. Revised prices are given in the selected market quotations.

Metals.

The metal markets all round are dull and weaker, with lower levels for all, with the exception of tin. The tin market is firm, but dull on account of buyers staying out of the market. There is also little interest being shown in copper, and the market is entirely a nominal one. Spelter has reacted after the advance recorded last week, and lead has also declined slightly. Antimony and aluminum have both declined, and quotations are nominal.

Tin.—The market is stagnant and void of all interest. Buyers have continued to stay out, and the extreme dullness is reflected in the tone being easier. Tin is unchanged at 39c per pound.

Spelter.—The market is dull and lower, with business very dull. Outside of a fair demand for prompt shipments there is nothing doing, futures being entirely neglected. Spelter has declined 1c, and is quoted at 18c per pound.

Copper.—The market is dull, and little interest is being shown by consumers. Quotations have declined ½c, and are nominal at 19c per pound.

Lead.—The market is unsettled and stagnant. The "Trust" has reduced the price to 4.70c, New York. Lead locally had declined ¼c, and is being quoted at 6¼ per pound.

Antimony.—The market is dull and weaker on light demand. Antimony has declined 2c, and is being quoted at 38c per pound.

Aluminum.—The market is entirely nominal. Supplies are so scarce that it is almost impossible to get any aluminum for spot delivery. Quotations are nominal at 38c per pound.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Coaticook, Que.—E. O. Baldwin, Cutting street, will shortly be in the market for hoisting and carrying cranes.

Ford, Ont.—The Ford Motor Co. contemplate building a plant for making farm tractors. No definite plans have been made yet.

Brighton, Ont.—Thos. Garnet & Son contractors, of Port Hope, have commenced the construction of the building for the D. J. Barker Foundry Co. The main structure will be of brick, 220 by 100 feet. Jas. Hickey is manager.

Welland, Ont.—Preparations are being made to re-open the local plant of the Canadian Steel Foundries, Ltd. Operations will first begin in the foundry on shell billets and the rolling mill may open later. Mr. Gilmore is the manager.

Ottawa, Ont.—It is reported that the Government may turn the shops of the Sorel shipyard into a factory for shells, as well as using a private owned factory there for that purpose. This course has been urged by a delegation of members of Parliament for the district.

Electrical

Crediton, Ont.—The council are considering the installation of a power distribution and lighting system.

Granton, Ont.—The town council propose to install a hydro-electric system at a cost of approximately $5,000.

Toronto, Ont.—The Provincial Hydro-electric Commission favor the building of a line from Chatham to Petrolea and Oil City, a distance of about 24 miles. Authority has been given to construct a transmission line for Granton, Kirkton and Exeter, about 24 miles, and also a line from Lucan to Ailsa Craig, nine or ten miles. It is expected that power will be turned on at Eugenia Falls about the first of next month.

Municipal

The Pas, Man.—Work will be proceeded with on the waterworks and sewage disposal plant.

Edmonton, Alta.—Work has started on the sewage disposal plant. The cost is estimated at $30,000.

Liverpool, N.S.—The Town Council contemplate making improvements to the municipal electric light plant.

Brantford, Ont.—The Fire and Light Committee have decided to purchase a motor truck for the fire department.

Esquimalt, B.C.—The City Council contemplates submitting by-laws to the ratepayers to authorize the raising of $30,000 by debentures to provide for the building of a fire hall and the purchase of fire apparatus.

Armagh, Que.—The Armagh Electric Co. propose to supply light and power to several villages in the County of Bellechasse. Joseph Leclere, Mayor of St. Charles, Que., is president of the company. Contracts will probably be let shortly.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Atache, Russian Embassy, Washington, D.C.

Windsor, Ont.—Definite steps for the acquisition of the street railway lines in Windsor, Walkerville, and Sandwich by the municipal interest will shortly be taken if a recommendation of the Ontario Hydro Commission meets with the approval of the councils of the three townships.

General Industrial

Montreal, Que.—Robin Bros. are building an extension to their factory.

Redvers, Sask.—The Imperial Oil Co. has obtained a track site here and will erect tanks this fall.

Winnipeg, Man.—The Peabody Overall Co., of Walkerville, Ont., may build a factory here for supplying the West.

Montreal, Que.—The Mount Royal Color & Varnish Co. will build an extension to their factory at a cost of $20,000.

Brantford, Ont.—The Brantford Cordage Co. will build an addition to their factory. C. L. Messecar is the general manager.

Salem, Ont.—The Salem tannery was burned down on September 4, and is a total loss, this being estimated at $3,000, with $1,000 insurance.

Chatham, Ont.—The Ideal Electrical Mfg. Co. of Wallaceburg is going to move to the city shortly. This is among the oldest establishment in Canada making electrical heating goods.

Contracts Awarded

Berlin, Ont.—George Moogk, of Weston, has been awarded the contract for the construction of an extension to the sewer disposal plant this fall. His tender amounted to $43,512.75.

Lachine, Que.—The City Council have awarded a contract for the construction of an incinerator of the "Decarie" type to the Atlas Construction Co. of Montreal. The plant will have a capacity of 20 tons per 24 hours.

Hull, Que.—The City Council has awarded the general contract for the construction of a hydro-electric plant to the Canadian General Electric Co. at $34,840. Works include power house, draft tube, open flume and gates.

Tenders

Victoria, B.C—The City Council have for sale a quantity of contractors' equipment. Full information may be obtained from the city purchasing agent at the City Hall.

Chatham, Ont.—The city engineer, F. P. Adams, is open to receive tenders for the machinery and equipment of the Chatham electric light plant, which consists principally of gas engines and producers, and electric generators.

Forging and Machining Shells in a Locomotive Works

Staff Article

In the plant here described, an output of 3,000 shrapnel of 3.3 diameter and about 1,500 or 1,800 high explosive shells of 4.5 calibre is being forged each 24 hours. The machining on the 3.3 shrapnel is proceeding almost as fast as the equipment can handle the work and a large shop is being equipped for machining the equivalent in 4.5 howitzer shells.

AMONG the many Canadian plants engaged in the production of war munitions, the most advantageously situated seem to be those which do both the forging and machining of shrapnel and explosive shells.

When the question of manufacture of these implements of war was first brought to the notice of the Canadian industrial world, it appeared to be a somewhat difficult matter to decide just where a start was to be made, but when the question of supply was taken over by a Commission of men well fitted and adapted to the control of an urgent and serious situation, a system was planned and developed whereby shell manufacture has not only been accomplished with good success, but at the present time is one of the greatest activities in progress throughout the length and breadth of our Dominion.

At the initiation of this new industry, forging was done principally, if not entirely, by our large steel plants and foundries, but as the demand for forgings became more and more insistent, developments naturally followed, with the result that at the present time many plants are producing shells all the way from the unforged billet to the final loading. Among the first to undertake this branch of the new activity were our large locomotive works.

Cutting Off the Billets.

In the production of 3.3 shrapnel shells in this particular plant, the $3\frac{1}{2}$-inch bars of 0.50 carbon steel are received from the mills in various lengths and are cut up into billets $4\frac{7}{8}$ in. long. The billets are produced in a number of different machines. A "Newton" cold saw is employed in cutting off four pieces at a time, blocks having the necessary shape being placed between the jaws of the vises so that the teeth of the saw start cutting on the four bars at once.

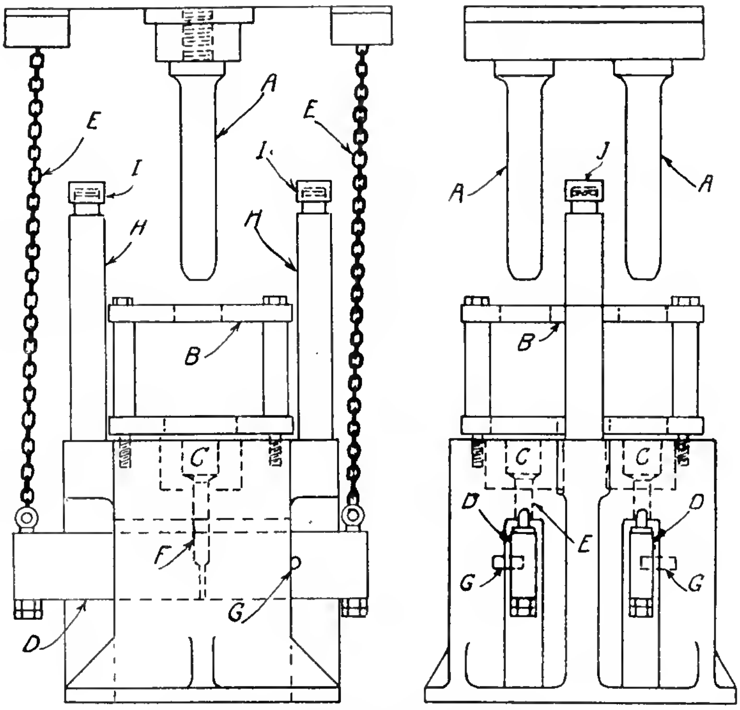

FIG. 2. GENERAL FEATURES OF R. D. WOOD CO. PRESS ATTACHMENTS.

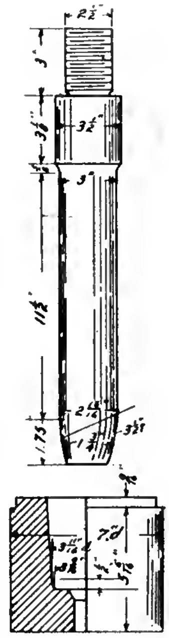

FIG. 2A. PUNCH AND DIE FOR PIERCING.

Planers were at one time used to cut the bars into billet lengths, but this method has now been discontinued. A very much similar arrangement is, however, employed on two large "Niles-Bement-Pond" millers as indicated in Fig. 1. Clamping devices rigidly secured to the table hold 32 bars at one setting and eight large Disston cold saws cut off the billets. The travel of the table is completed in thout two hours, and when it has gone about half way, men at the rear remove the billets and set up another set of bars in their place, so that when the table has completed its travel the cutting arbor is raised and the table returned to commence cutting at the other end. The later cut billets are then removed and are replaced by bars, the cutting-off process being thereby almost continuous. This accomplishment

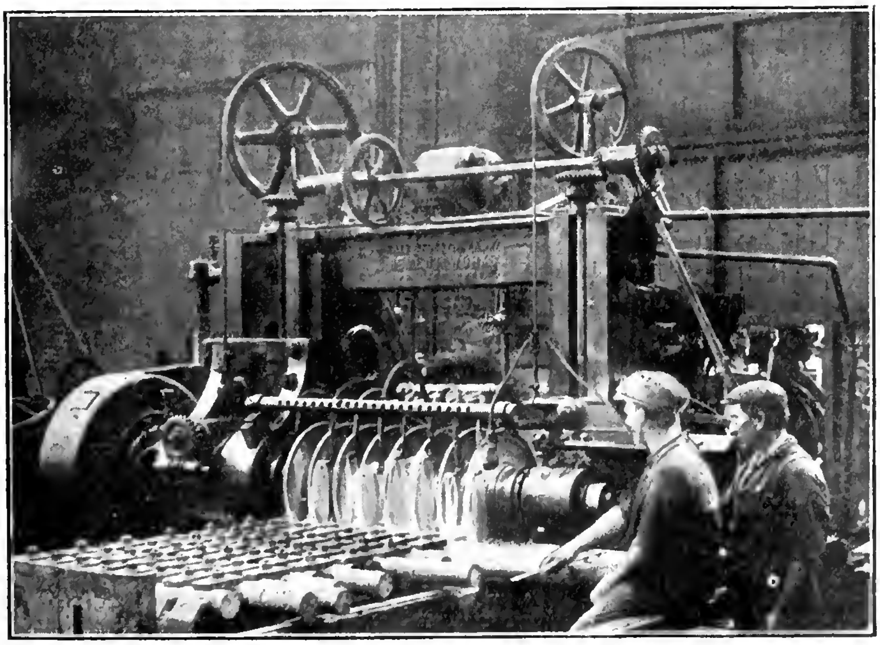

FIG. 1. CUTTING-OFF 3.3 HIGH EXPLOSIVE SHELL BILLETS ON A "NILES-BEMENT-POND" MILLER.

was impossible in the case of the planer. At each traverse of the table 250 billets are secured. A third and similar machine will soon be in operation for the production of billets.

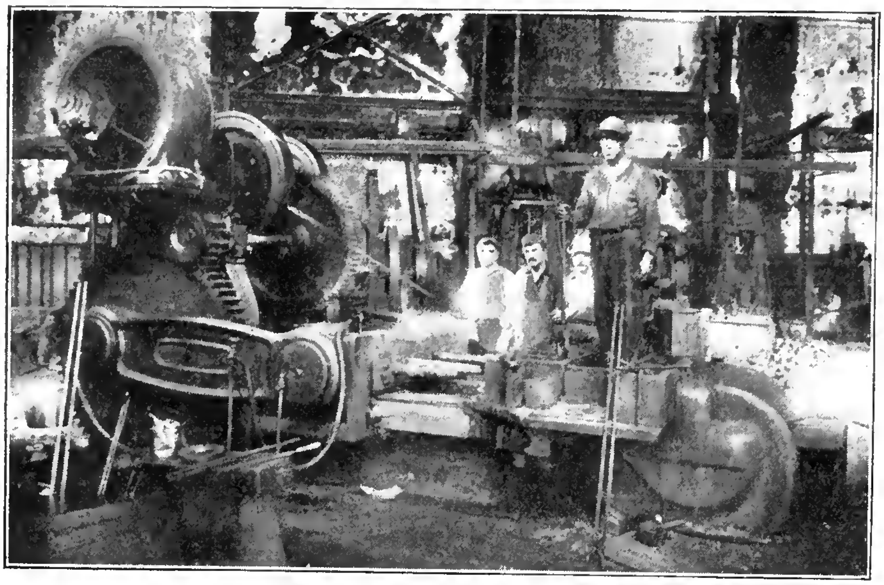

FIG. 3. BULLDOZER USED IN SECOND DRAWING OPERATION OF 3.3. SHRAPNEL SHELL FORGINGS.

Turret lathes are also used in cutting off billets, these having a capacity of about 260 per 10 hours.

Forging.

In preparation for forging, the billets are placed in furnaces made by the Ferguson Furnace Co. There are two of these furnaces to each press. The fuel used is crude oil, at a pressure of 25 lbs., mixed with air at a pressure of 7 ozs.

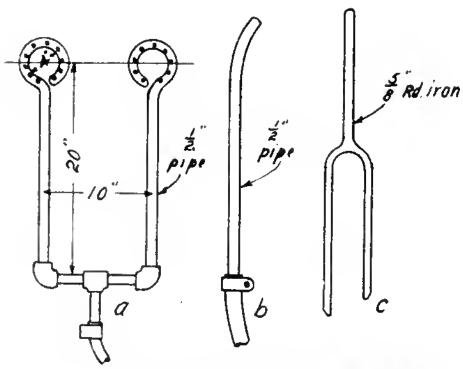

FIG. 3A. FORGING PRESS ACCESSORIES.

The presses installed were supplied by the R. D. Wood Co., Philadelphia, and Fig. 2 shows the general design of the different attachments.

The punches, A, are secured to the ram of the press, and in their downward stroke pass through the plate B, which is held up a certain distance by means of bolts and blocks as shown. This plate with the aid of a hand tool strips the stock from the punch after it has been pierced. The dies, C, are held in position in the bed of the press, while the cross-bar, D, is for the purpose of knocking out the block after the piercing has been performed.

This cross-bar D is held up by the two chains E on either side, the top end of these being secured to the moveable ram, which carries the punches. It will be noticed that the chains incline at an angle, the reason of this being that as the ram descends, and likewise the chains and cross-bar, the bar will fall away from the knock-out bolt F, and by action of gravity, the cross-bar will fall to a central position, and on the upward stroke, the solid part of the cross-bar comes in contact with the bolt F and ejects the work from the die.

When the ram has reached the top, the operator forces the cross-bar over until the stop pin G engages with the frame of the press, following which the knock-out bolt drops into the hole of the cross-bar. To regulate the stroke of the punch into the work, the caps I are placed on the top of the standards H, and as the punch wears or the piece I upsets, one or more washers shown at J are taken out.

In Fig 2A is shown a sketch of the punch and die used in the R. D. Wood presses for the piercing operation, and in Fig. 3 A are a few useful devices used while forging. A spraying arrangement for cooling the punches is shown at (a), and (b) is an air pipe for blowing the scale out of the dies; while (c) is a gauge for testing the length of the shell after drawing.

Piercing and Drawing.

In one section of the plant where two presses are conveniently placed, the piercing and drawing operations are accomplished at one heat, but in most cases it requires two heats to complete the forged shell.

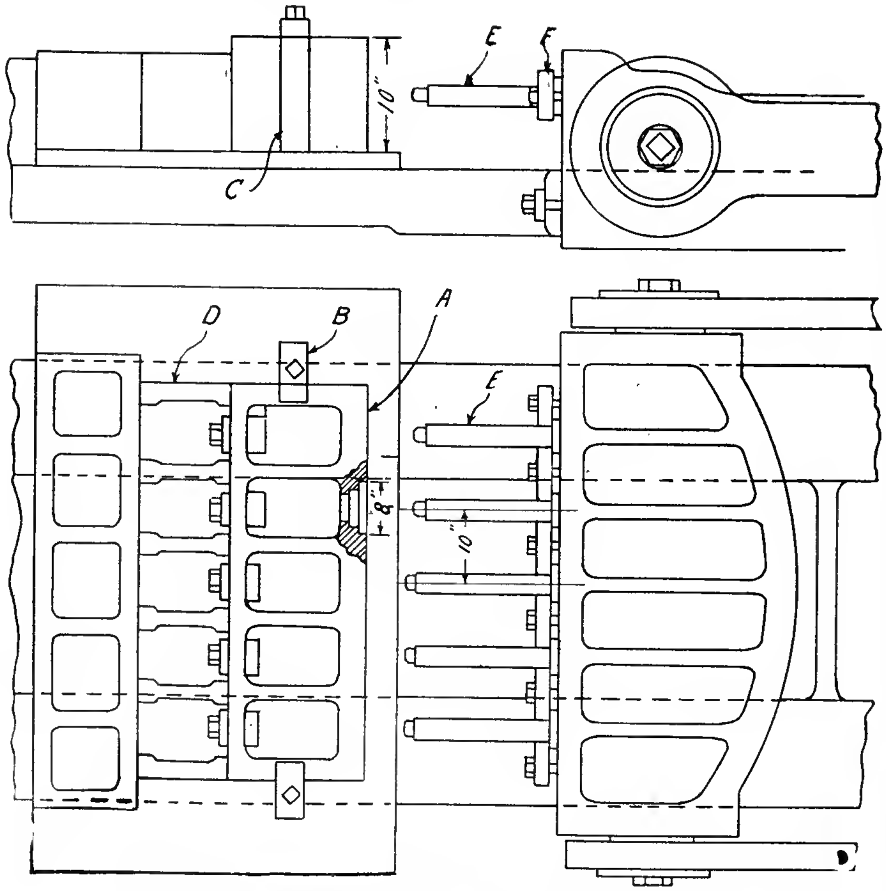

FIG. 4. CONSTRUCTIONAL FEATURES OF BULLDOZER ATTACHMENTS FOR DRAWING SHELL BILLETS AFTER PIERCING.

The Bulldozer.

Fig. 3 shows a large bulldozer used in drawing the shell after it has been pierced in one of the other presses. While in the hydraulic presses the shells are forced through the two or three dies at one time, one die being placed above the other, in the bulldozer each sizing die

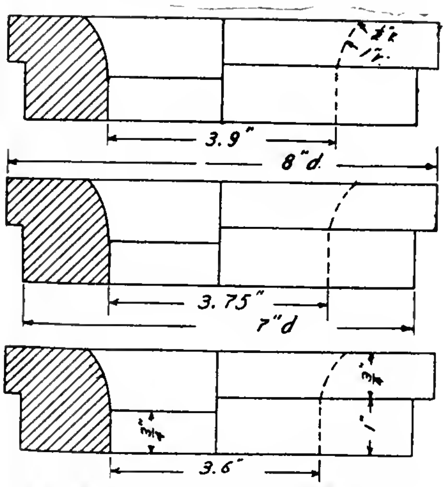

FIG. 5. FIRST, SECOND AND THIRD OPERATIONS ON BULLDOZER.

is separate. The pierced block is heated and passed to the man on the press, who receives it with a pair of tongs. The base end is then held in the die and the punch coming forward enters the hole and forces the piece through; in the interval, the man on the press changes his tongs for a stripper tool, similar to a fork, which passes over the punch as it protrudes through the die, and, in receding, the work is removed and passed on to the next die to be reduced in size.

The constructional features of the bulldozer are shown in Fig. 4. The large casting A which carries the drawing dies is held down on the table of the machine by means of the clamps B and blocks C. Distant pieces D are placed between the die block A and the tail-piece of the machine, so as to bring the dies into the desired position. Instead of screwing the punches E into the movable ram, they are made with a square shoulder and fastened in position by the clamps F. Fig. 5 is a sketch of the three dies used in the three draws on the bulldozer.

Automatic Attachments.

In the drawing operations on these presses, owing to the heat generated from the large furnaces and the nature of the work, there are times when through forgetfulness or carelessness, the movements of the attendants are sometimes slow, or inaccuracies arise in operating the various hand appliances for forming and stripping the shells. To eliminate these to some extent, the works engineer designed and constructed several attachments and placed them upon a large "Niles" hydraulic press. These automatic arrangements of stops and strippers are operated by levers, controlled from a cylinder supplied with compressed air. At the proper moment by action of trip-levers, these stops and strippers are brought into position, thus overcoming the uncertainty of the human element.

Forging Requisites.

In all these forging operations it is very important that a large percentage if not all of the scale should be removed before the shells are placed in the die. A jet of water is sometimes thrown on the block as it comes from the furnace, and by a sudden blow or the action of scrapers a great deal of the scale can be removed.

Proper lubrication is another essential feature in connection with the forging operations. In many cases, flake graphite or a solution of graphite and oil applied with a swab is being used with very good results. Proper temperature in heating should also be carefully considered to obtain satisfactory results. For the piercing operation a heat of 2,000 deg. F., and for the drawing operation 1,800 deg. F. is considered good practice.

Another important feature is the speed with which the operations are performed, an average speed of 30 feet per minute for piercing and a speed of about 22 feet for drawing, usually give satisfaction. Increasing or reducing these speeds previously gave some trouble. By

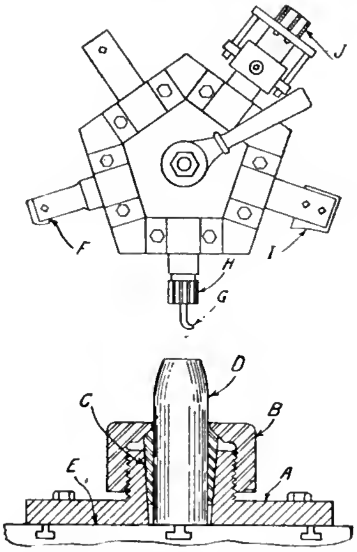

FIG. 6. CHUCK AND HEAD ON "BULLARD" VERTICAL TURRET LATHE.

proper heating and handling very few spoiled or rejected shells may be anticipated.

Inspection and Machining.

After the shells are inspected they are sent to the machine shop. The cycle of operations from the forging to the finished shell are similar in this plant to many of those already described in **Canadian Machinery**, and only a few operations and special appliances need therefore be mentioned here.

Machining Shell Nose.

Fig. 6 shows a special chuck used on the table of a "Bullard" vertical turret lathe for holding 3.3. shrapnel shells while the noses are being machined. The casting A is secured in a central position on the lathe table E, the bore of this piece being turned to fit the split bush C, the bore of which fits the shell after it has been rough turned. The nut B which is screwed down with a large wrench, forces the bush C down, securely gripping the shell D.

Directly above this jig is shown a sketch of the turret head carrying the tools required in the nosing and threading operations, which consist of face, bore and ream, undercut, turn contour and tap. A view of the operation is shown in Fig. 7.

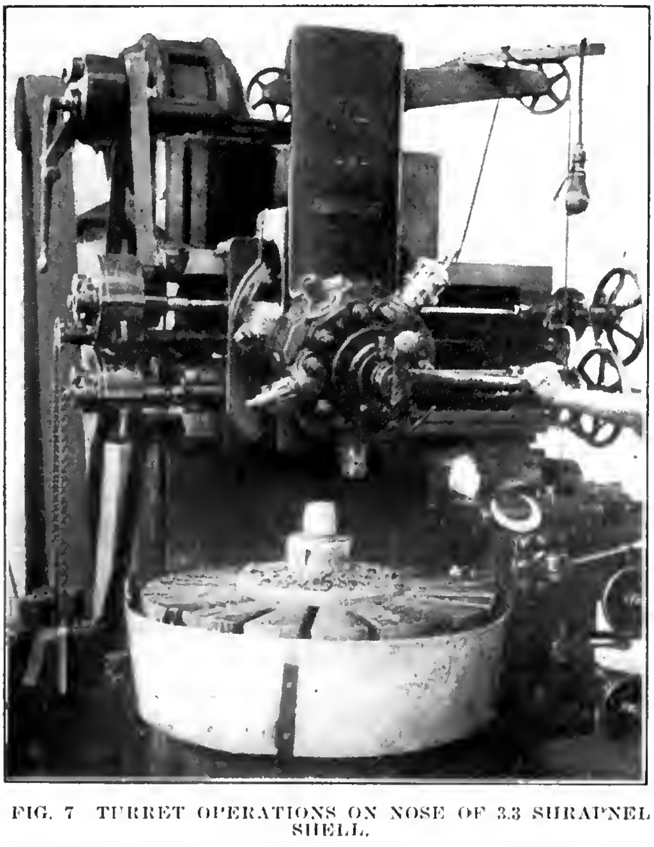

FIG. 7 TURRET OPERATIONS ON NOSE OF 3.3 SHRAPNEL SHELL.

Stop Gauge.

A very convenient stop gauge is shown in Fig. 8

for use when roughing out the groove for the copper band. The shell A being placed in the chuck B, the stop C (which is pivoted on the piece D, held

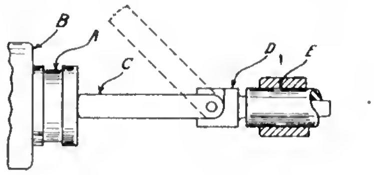

FIG. 8. STOP GAUGE.

in the tail-stock spindle E), is swung into a parallel position, and the shell brought forward until it strikes the stop, the chuck being then tightened and the stop swung clear as indicated by the dotted lines.

Fig. 9 shows a useful chuck for holding the shells while facing, or grooving and waving. It is somewhat similar to that shown in Fig. 6, only that the nut C bears on the split bush D on a flat surface instead of on a taper. A view of the bush D is shown to the right.

Dressing Wheels.

Many devices are employed for dressing formed grinding wheels, that shown in Fig. 10 being very convenient and serviceable. The compound rest A is placed

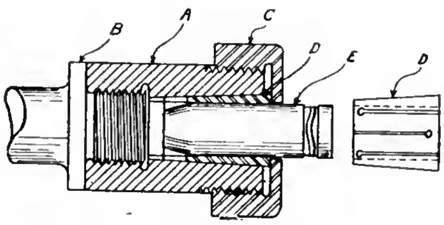

FIG. 9. SPECIAL CHUCK.

on the machine, a "Landis" grinder, to one side of the shell, and, when the wheel needs dressing, the table is brought back and the wheel dressed to shape. Secured in the slot is the forked piece B carrying the bell-crank piece C, which swings about the pin shown. The piece C carries at the lower end a diamond dresser which is held in position by the set-screw; this piece C also carries a roller E which is kept in contact with the cam D by the action of the spring beneath the tail of the piece C.

Special Driving Chuck.

Another simple and useful contrivance is shown in Fig. 11, its purpose being to hold the shells while the copper band is being turned. The friction chuck which drives the shell is held in lathe spindle A, and to support the finished end of the shell, the device shown gives very satisfactory results. The piece E which is held in the tail-stock spindle F has a stem on its outer end which carries the revolving piece D, this latter being recessed on the end to fit the base of the finished shell. To avoid undue friction, a number of balls are used between the two surfaces.

Lead Pot Heating.

In connection with the nosing of 3.3 shrapnel shells, the open ends are heated in a pot of molten lead, a sketch of the latter being shown in Fig. 12. This pot is placed in a furnace built of boiler plate and fire brick, the fuel used being crude oil. For some time, owing to the evaporation and lead clinging to the heated shells, a loss of 100 lbs. of lead for every 120 shells nosed was sustained.

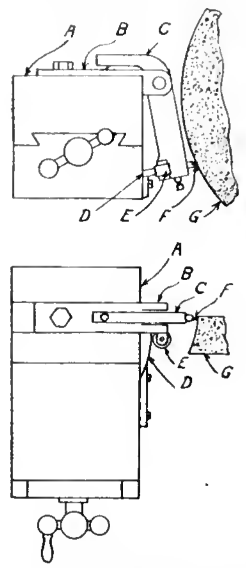

FIG. 10. JIG FOR DRESSING EMERY WHEEL.

The works chemists suggested covering the surface of the lead with broken charcoal, with the result that the wastage is now only about 20 lbs. per 500 shells, the bulk of which is what sticks to the latter. In all lead-pot heating, the charcoal protection is advisable, as, unprotected, the lead hardens and depreciates rapidly.

Forging 4.5 H. E. Shells.

High explosive shells of the 4.5 size are also being produced in this plant. The billets are received from an adjacent steel foundry, being there cast in ingots about 30 inches long, each ingot making two billets. About 40 per cent. of the ingot at the top is removed to avoid the possibility of a "pipe."

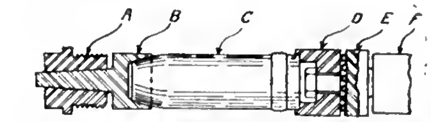

FIG. 11. CHUCK AND BALL-BEARING CENTRE.

The forging of these billets into rough shells for 4.5 projectiles is at present being done in one operation, but not with entire success. Much experimenting is being carried on in the hope that one operation may be all that is necessary. Trouble is being experienced with the walls varying in thickness to the extent that a number of the rough forgings do not pass inspection.

Machining 4.5 H. E. Shells.

In the machining of the 4.5 high explosive shells, eight to ten American Tool Co. lathes and about thirty R. K. Leblond lathes fitted with turrets are employed, while for threading the recess in the shell base, "Lees-Bradner" threading machines are installed. The sequence of operations is similar to those of the 3.3 shrapnel, and along the lines

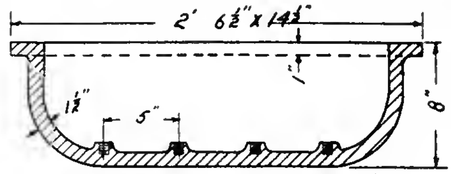

FIG. 12. LEAD MELTING POT.

described in previous articles in **Canadian Machinery.**

For facing off the base, the shells are held in the device shown in Fig. 13. Old engine lathes and cutting-off machines are also employed on this operation. The shells are next centered and rough turned.

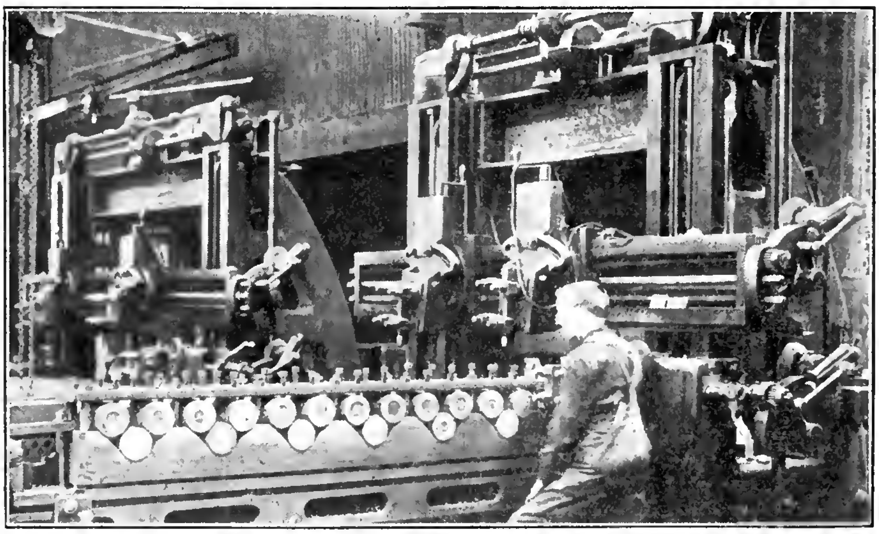

FIG. 13. FACING OFF BASES OF 4.5 HIGH EXPLOSIVE SHELLS.

The boring is accomplished by holding the shell in a chuck similar to that shown in Fig. 9, and the operation is performed as indicated by Fig. 14. The powder chamber is roughed, and the nose shaped inside with the first tool shown in the figure. The second tool is for boring and the last for finishing the bore and powder chamber.

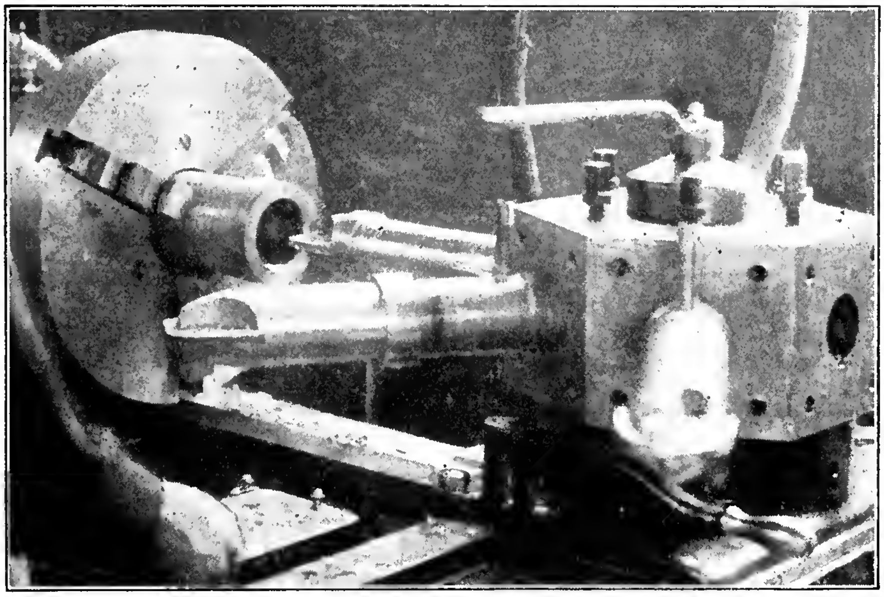

FIG. 14. BORING 4.5 H. E. SHELLS ON A 21-IN. "LE BLOND" HIGH DUTY LATHE.

After the shells have been nosed in the nosing press, they are finish turned, the contour of nose is formed; the grooving and waving is completed, and the inside of nose finished and tapped. This operation is shown in Fig. 15. The nose is rough bored and reamed, shaped at base of thread, grooved and tapped with "Murchey" collapsible tap. During these operations the shells are held in a chuck similar to that shown in Fig. 9, but larger.

After the machining is completed the interior is varnished and afterwards baked in an oven or hot plate for several hours at a temperature of about 300 degs. F. The brass sockets are next screwed in, the finishing of same being performed on 21-in. "LeBlond" lathes.

FIG. 15. FINISHING INSIDE NOSE OF 4.5 H. E. SHELL ON A 21-IN. HIGH DUTY "LE BLOND" LATHE.

EFFECT OF HUMIDITY ON LEATHER BELTING

IN a paper on "The Effect of Humidity on Leather Belting," presented at the Buffalo meeting of the American Society of Mechanical Engineers, the following conclusions were arrived at:—

(1)—If a belt be set up at low relative humidity, slipping will probably occur if the relative humidity increases to any great extent, especially if accompanied by a rise in temperature.

(2)—If a belt be set up at high relative humidity excessive pressure on the bearings and stretching of the belt will result from a decided decrease in relative humidity, especially if accompanied by a fall in temperature.

(3)—If a belt be set up at a medium relative humidity, the tensions will not be excessive at lower relative humidities, nor will there be any great danger of slipping at high relative humidities unless accompanied by excessive temperature changes. In other words, the factor of safety in the ordinary belt rules is sufficient to provide for the effect of changes in the relative humidity, if the set-up be made at a medium per cent. of relative humidity.

(4)—If a belt be set up at any relative humidity with a spring or gravity tightener, a load 50 per cent. greater than the standard can be transmitted at either high or low humidity without encountering any danger of stretching the belt, of slipping, or of any excessive pressure on the bearings.

NOVA SCOTIA STEEL & COAL CO.

IT is learned on good authority that during the month of August nearly 220,000 forgings for shrapnel and high explosive shells were manufactured by the Nova Scotia Steel & Coal Co. This output exceeded that of the previous month by 25 per cent., and was the best month the company has experienced since its entry into the munition business.

At the present time four sizes of shells are being forged. Besides completing approximately 10,000 forgings daily, the company is turning out about 1,000 complete shells. Up to the present it has turned out nearly two million forgings, which have been distributed among Canadian firms participating in shell machining.

In addition to the shell business there is much manufacturing activity in heavy marine forgings for shipbuilding concerns on the Clyde. Before the outbreak of hostilities nearly all work of this class was handled by German firms. Last fall an order was received for 3,000 tons, and it will not be completed until about the end of the year.

The Scotia Company will have the biggest steel output this year in its history. At present the greater part of the mill is being worked twenty-four hours a day, divided into three eight-hour shifts. There are about four thousand men on the payroll.

Operations at the Eastern Car Co., a subsidiary, are not yet at capacity, but this is entirely due to lack of suitable labor. About forty cars per day are now being manufactured, and it is expected that this output will be increased to fifty cars within the next few weeks. All this business is for export.

EMERGENCY GEAR CUTTING

By S. Simpson

THE machine for knurling small brass gear teeth described by Avery E. Granville in Aug. 26 issue of **Canadian Machinery** represents what is presumably one of the latest developments of gear making equipment. Having frequent repairs to make to all kinds of talking machines, the writer is occasionally called upon to make an odd gear, and the method adopted, while ef-

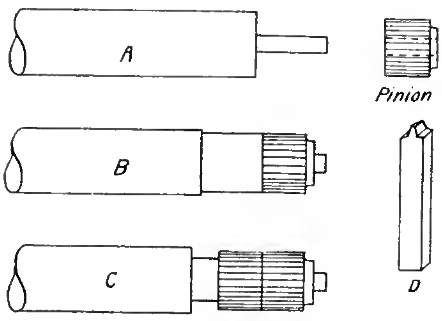

FIG. 1. EMERGENCY GEAR CUTTING.

fective, forms so great a contrast that a brief description may be of interest to your readers.

Owing to the lack of a dividing head or a milling machine, the work had to be done in a lathe. To begin with, chuck a piece of brass rod or cold-rolled steel, as the case may be, and turn it down as shown at A, Fig. 1. Make the end a suitable driving fit for the old pinion so that it can be driven on without distortion, either of itself or the rod; see B, Fig. 1. Now turn tbe rod to the same size as the pinion, just touching the tops of

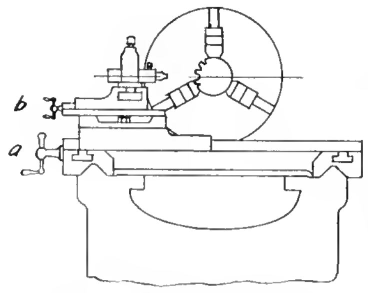

FIG. 2. EMERGENCY GEAR CUTTING.

the teeth with the tool. Carry the cut far enough along to allow the full width of teeth on the new gear, and then recess as at C, Fig. 1. Make the diameter of this recess just slightly smaller than the bottom of the teeth of the old pinion.

A piece of square tool steel is now filed up carefully to fit the space between the teeth of the old pinion, due allowance being made for effects of wear where noticetble; see D, Fig. 1. This tool is now fastened in the tool post with its cutting edge facing toward the chuck, being set level with the centre. The chuck is then moved round till the tool feeds in free, and bottoms between the teeth. The chuck is next wedged tightly with a block of wood, after which work may be started. The carriage, Fig. 2, is fed sideways by handle (a), the depth of the cut being adjusted by handle (b). After cutting one tooth, the wedge is loosened and the chuck moved round till the next space in the old gear is matched up with the cutting tool.

After completing the teeth, the stock is bored from the inside of the old pinion a hole o,f the proper size being carried through far enough so that when cut off on the other side, the new pinion has a finished hole and is completely machined.

TOOL STEEL FROM SCRAP.

By E. Avery

AN Eastern man claims to have perfected a process by which he can easily change almost any piece of ordinary iron into tool steel. The process is very similar to that of case-hardening, but goes entirely through thin metal, and much deeper into thick pieces, than does case-hardening in the same time. He calls it "infusion" and the mixture he uses to accomplish his results is a secret. After being treated, the metal is hardened and tempered in the ordinary way, and the results are surprising in some

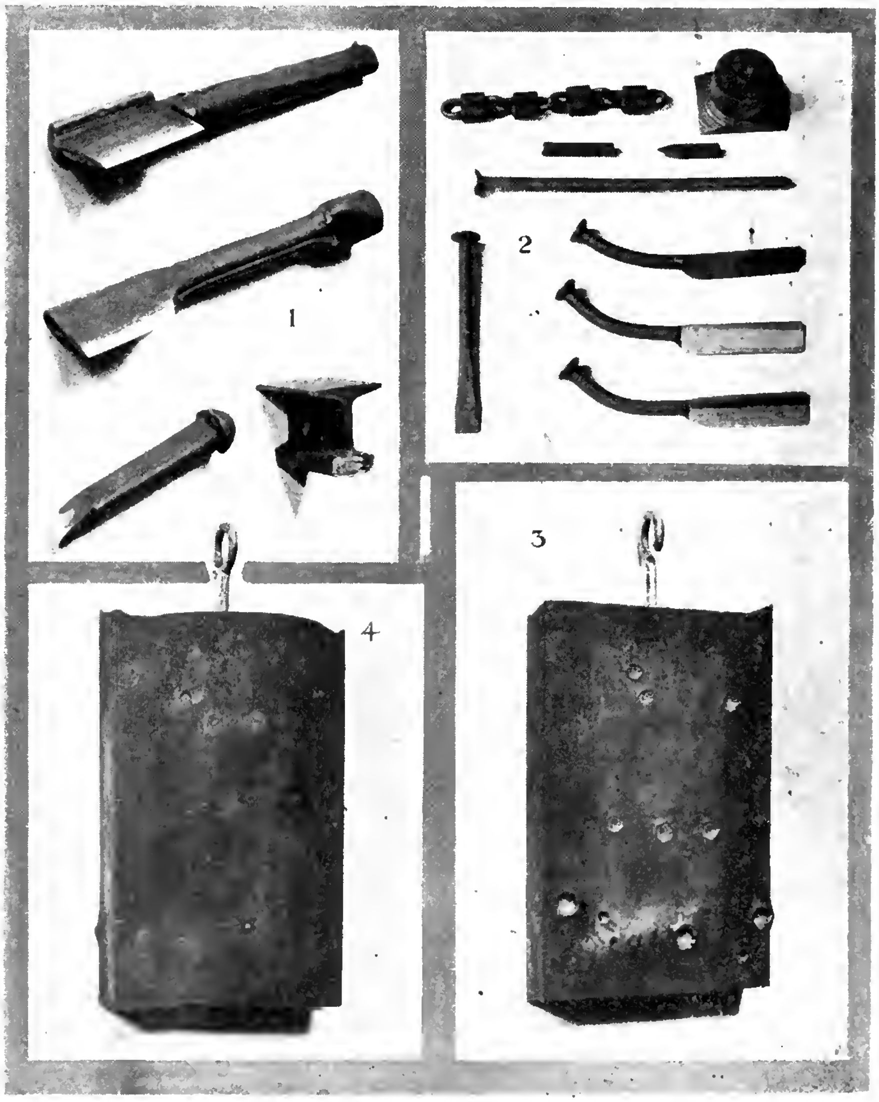

FIG. 1. RAZORS MADE FROM GAS PIPE, AND A LATHE TOOL MADE FROM A RAILROAD SPIKE. FIG. 2. RAZORS AND CHISEL MADE FROM WIRE NAILS. FIG. 3. EFFECT OF BULLETS ON UNTREATED PLATES. FIG. 4. BULLET MARKS SCARCELY SHOW ON TREATED PLATES.

instances. His claim is that his process enables a manufacturer to buy cheap steel, which can be easily machined into milling cutters, gears, or other things, and then, treated by his process for a trifling sum, changed into a high-grade of tool steel with all the properties of the best steel of this kind. While manufacturers in general have looked upon the process with suspicion, and demand rigid tests before trying it, some of his results are interesting.

Fig.1 shows two razors made from pieces of ordinary gas pipe, and a lathe tool made from a railroad spike. The piece of railroad rail shown, was used as a test piece. The razors and tool, gave very satisfactory results, when properly used.

Fig. 2 shows three razors and a chisel made from common wire nails, together with some miscellaneous parts. These all compared favorably with similar tools of first class steel.

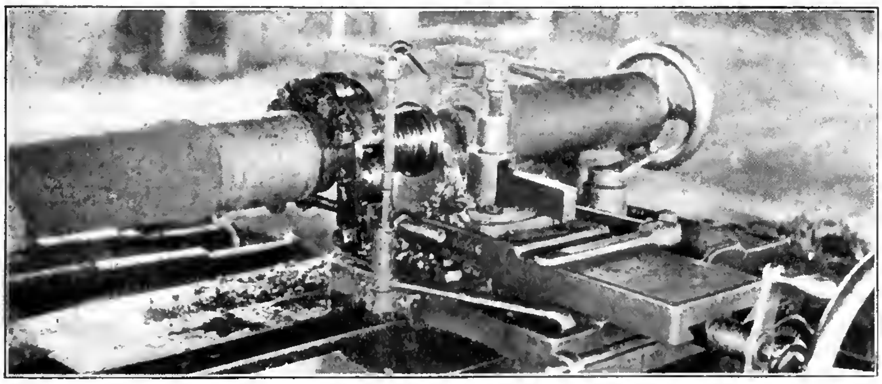
Fig. 3 shows a large untreated iron plate which was fired at with a Springfield rifle, the bullets making very noticeable indentations.

Fig. 4 shows a treated plate, subjected to the same test, the bullet marks scarcely showing.

AN AXLE ROLLER

By G. Edwards

ONE of the shops of the Pennsylvania Railroad system uses the device shown for rolling car axles after they are turned. This gives the bearing surface a hard smooth finish that cuts the journals less than if the axle were merely finish-turned. The device consists of three hardened rollers set in links so as to bear about 120 deg. apart when applied to the axle. Pressure is supplied by means of an eye-bolt, the nut of which is tightened sufficiently to give the right finish. The bracket holding the device is bolted to the side of the lathe carriage, and the eye-bolt has a pin in it which locks it to the end link which may be easily removed when the tension is released. This allows the links to be disengaged and swung back out of the way while the bearing is being turned in the first place. When the rollers are in place they are fed along by means of the power feed exactly the same as is the cutting tool.

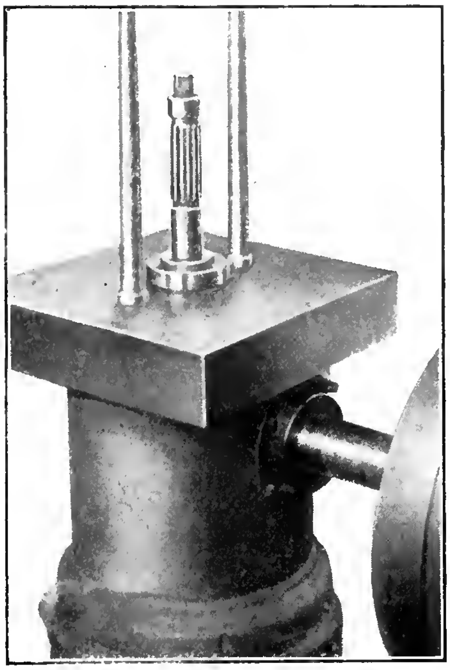


DEVICE FOR ROLLING CAR AXLES AFTER BEING TURNED

PULLEY REAMING MACHINE

By A. E. G.

A CONCERN having a large number of pulleys to ream, built the machine shown.



PULLEY REAMING MACHINE.

Adjustable reamers are used in the spindle, which is provided with bushings for holding various sized shanks. The bored-out pulley is placed over the reamer so that the arms or spokes will rest against the two uprights set into the table; the pulley is then slowly pressed downward. The bushings in the spindle do not clamp the reamer shank but merely hold it central, the driving being done by means of the square on the end of the shank. This allows the reamer to be lifted out as soon as the pulley has been reamed, and does away with the necessity of running the reamer back through the hole.

CUTTING QUALITY AND HARDNESS

A GOOD many many machinists hold the mistaken notion that hardness in a cutting tool is the same thing as cutting ability, and are disposed to condemn or approve a tool according as it can or cannot be scratched with a file, says a writer in the "Manchester Guardian." The fact is, of course, that extreme hardness is only of service in rare cases when very hard metals have to be machined, and that for the general run of work a tool that can easily be filed may give the best results.

Particularly does this apply to modern high-speed steels, for these, when hardened to perfection for heavy cuts in mild steel or cast iron, hardly ever exhibit extreme hardness. In the case of lathe tools, one reason for this probably is that in heavy and fast cutting the point of the tool plays little part in severing the chip from the body of the work; the separation proceeding by a continuous splitting action which opens out a way for the point. Consequently, with even a moderately soft point, the edge is not easily rounded and the action in any case not much impeded.

In the case of high-speed drills working in mild iron or steel, extreme hardness is to be avoided, or trouble will arise from the snipping of the cutting edge and the breaking of the drill itself. A cutting tool should, therefore, never be judged by its hardness as tested by filing, but solely by its performance of the task for which it is intended.

CANADIAN FORD CO.

BIG things are expected of the Ford Motor Co. of Canada, of Ford, Ont. Net earnings for the present year are estimated at $3,000,000, or 300 per cent. on the capital stock. People in Detroit, who are in close touch with the company, express the opinion that a stock dividend between 600 and 700 per cent. will probably be announced this fall. The regular dividend is 40 per cent. cash per annum.

The company has a record for making distributions in stock, and its present capital, $1,000,000, represents a growth from $125,000 in 1906 through the declaration of stock dividends.

Through agreement with Henry Ford, the company sells Ford products without competition in Canada and the British Colonies, which includes Australia, India, British South Africa and New Zealand. It does not, however, sell in the British Isles.

In 1912, the Ford Motor Co. of Canada sold 6,300 cars; in 1913 it sold 11,000; in 1914, 16,500; while this year's business, notwithstanding adverse conditions in many parts of its field, will be close to 25,000 cars.

NEW PROCESS DEVELOPMENTS

Inventive Genius and Research Operate to a Dual End — They Aim to Improve What We Now Possess and Bring to Our Service Commodities Before Unknown

ELECTRIC ARC WELDING*

By Lieut. C. S. McDowell, U.S.N.

WELDING is the joining of two pieces of metal of like or unlike characteristics by fusion, while in the plastic state. The old definition of welding was the process of uniting two pieces of metal by hammering them together while hot enough to be plastic. Modern methods, however, of obtaining high temperatures by means of gases and electricity, has broadened the definition of welding and brought in use additional processes, to which the term "welding" has been applied. It is the purpose in this article to describe only the Electric-Arc Welding process, which it is predicted will rapidly become the standard method of joining sheet metals of all thicknesses, reclaiming castings, repairing broken machinery of all kinds, building up of worn parts, welding seams in new boilers, tanks, etc., making of high-speed tools, repairing boilers, etc., and an arc-welding equipment will be a necessary adjunct to every properly-equipped machine shop.

Conditions for Successful Welding

The essential characteristics of a successful weld are:—That the metal in the welded joint shall be free from impurities, slag and defects of all sorts; that it shall possess a sufficient amount of elongation, flexibility and tensile strength; and that the process of welding shall be such as to reduce to a minimum disturbances in the texture of the surrounding metal. In certain classes of work, flexibility and elongation in the weld is of more importance than tensile strength. The quality of the weld obtained with electric welding is dependent on the following:—

1.—The furnishing of the correct amount of energy at the weld for obtaining of the proper working temperatures of the material to be welded.

2.—The quality of the metal electrodes (the welding wire).

3. The skill of the operator.

The Correct Amount of Energy

The material worked on, the anode, is heated by the impinging of the cathode stream, by the julean heat developed by the ohmic contact resistance and by the radiant heat given off the arc: the metallic pencil or cathode is heated by the julean heat due to its ohmic resistance to current flowing and by the slight contact resistance at the electrode surface. The greater proportion of the heat generated at the arc is at the anode, or material being welded (approximately 75 per cent. of the total heat), when the metallic arc is used. This is quite satisfactory due to the greater means of dissipation at the anode by radiation, convection and conduction.

Practically all the energy supplied to the arc is dissipated as heat, only a slight proportion being given off as light, and to regulate the amount of heat units and thereby the temperature of a particular shape and class of material, it is essential to regulate the amount of energy supplied to the arc as measured in watts. The maximum temperature of steel in the usual converter is approximately 1,800 degrees C., the melting being approximately 1,400 degrees C. The temperature of boiling steel at atmospheric pressure is approximately 2,450 degrees C., while the temperature of the arc stream may greatly exceed this. The result is that in electric-arc welding steel is being worked near a critical temperature.

The material to be welded should be in a plastic state sufficient for the proper intermixing of the metal and obtaining of perfect fusion: if the temperature be too low the added material will not adhere to the original metal and the weld will fall apart at the surface: on the other hand, if too high a temperature is obtained the metal will be burnt and the weld will be greatly weakened by slag thus formed and will be of coarse and irregular structures. The surfaces of the metals to be welded must tend to cohere to a marked extent, and the working temperature must be that at which the foregoing condition is most prominent.

Welding Condition Feature

The best welding condition for iron and steel exists within a limited range of temperature only. The safe working temperature depends somewhat on the material to be welded; an operator quickly obtains the necessary experience to tell if he has the proper temperature. The amount of energy necessary to obtain the proper temperature at the weld depends upon the size and shape of the piece worked on, it being the amount of energy necessary to supply the heat losses and keep the weld constantly at the proper welding temperature. The amount of energy required varies as the whole mass of the article becomes heated, a greater amount being required at first when the mass is cold; for this reason it is important in order to obtain consistent results to have a control of the energy at the operator's end of the line. This control should require very few changes in the supplied energy and is not to overcome the variation of energy due to changes in arc length. The temperature at the weld should remain practically constant; a momentary inrush of current will burn the metal at that point and cause a flaw with the chances of reducing the tensile strength of the weld 50 per cent., or even more.

Electrodes

There are two methods of electric-arc welding: one, the Benardes process, in which a carbon electrode is used; and the other, the Slavinoff process, in which the metallic electrode is used. As a result of the tests which have been conducted, and from the experience of others in electric-arc welding, it is believed that the carbon-electrode process is not suited for general work, some of the reasons being that much greater difficulty is experienced in maintaining the proper temperature, and there are more chances of getting an excess of carbon in the weld.

In the Slavinoff process, which is nearly universally employed at present, it is necessary to have the metal electrodes of such material that the deposited metal in the weld shall have practically the same characteristics as the rest of the metal of the object worked on. As certain of the constituents of the electrode are partially lost in the arc, it is usually necessary to have the electrode contain an excess of certain materials over what is desired in the finished weld. The amount of the loss of these constituents depends upon the temperature, and it is necessary in order to obtain desired and consistent characteristics in the finished weld to have a constant temperature at the weld. The steel companies will guarantee the results with the electrodes which they supply, only if the system of arc welding with which they are used can maintain a constant temperature at the weld.

The Operator

A certain amount of skill and experience is required of the operator, no matter what system of electric welding may be used: but some types of outfits require much more skill and closer attention than others, and it is considered essential that the ideal system should require a minimum of experience and only normal mechanical skill. A system which depends primarily on the skill

*From a paper read before the American Society of Naval Architects.

of the operator cannot turn out consistent work and is not suited to all services.

Fixtures

Certain companies claim that a flux is necessary to obtain good results, but in the tests conducted, all sorts of material and in all positions have been welded, and the best results have been obtained from system in which no flux is used. The claims in favor of the flux are that it blankets the weld by forming a gas around the material which prevents oxygen reaching it and thereby prevents oxidation. This has been proven not necessary, by making similar welds first where oxygen was entirely excluded, and then under normal conditions in the air; there being no difference in strength or structure of the weld.

Another claim is that the flux acts as a scavenger to remove impurities from the weld, but it cannot act in this way unless the metal actually boils, and this is a condition which, as previously shown, should be avoided. There are also certain users who believe a flux necessary for overhead work; but, in tests conducted, as good and consistent welds were obtained when welding overhead without a flux as in any other position. It is considered that in a good electrical welding system a flux is not necessary, and is simply an added expense and complication.

Automatic Control

While it is recognized that it is desirable to have as simple an equipment as possible, it is considered necessary to have an automatic control of the input energy to the weld, the reasons for which have been previously mentioned, so that when the proper amount of energy has been determined for a particular job it will remain constant regardless of the varying of the arc length.

A system with fixed resistances depends entirely on the skill of the operator in maintaining his arc length constant and thereby the energy constant. This system gives good results at times, but our tests showed that even with a skilled operator, furnished by the manufacturer, tensile strengths varying as much as 50 per cent. on the same class of material were obtained. It should be possible for the operator to set the current controlled at the desired amount as well as at the panel board; the controller should automatically keep the current approximately at the fixed value. A variation of less than 5 per cent. can be obtained with a well designed equipment.

Cutting

The electric arc has been found suitable for cutting, but a carbon electrode must be used; no automatic-current control is necessary, although a choke coil is advisable to prevent large inrushes of current. The amount of current varies with the size of the material to cut; from 250 to 400 amperes being required for burning off rivet heads and light section plates, while from 500 to 800 ampères may be required on plates 4 inches thick. This is a momentary load, however, and a 300-ampère continuous-duty machine is considered sufficient. It is necessary to cut away the edges of the cut and remove the burnt metal.

Preparation of Material to be Welded

The material to be welded should be cleaned with a scraper or wire brush to remove oxides and prevent forming of slag, and it is also necessary to bevel the edge sufficiently so that the distance from the electrode to bottom of the weld is less than that of the electrode to any other part of the article, so that the arc will not stray. In thick plates, where possible, and especially in castings, it is usual to weld from both sides, and in this case the original material is pointed by beveling on both sides.

Applications of Arc Welding

During the past year the New York Navy Yard has had contract electric welding done on boilers of various ships. Certain defective castings have been welded, blow holes filled in others, and miscellaneous repair work has been done while the various machines were under test. Additional uses are being developed as the advantages of the method became better known. A large saving in cost over other methods of repair have been made on boiler jobs, in addition to a saving in time, notwithstanding the large profit which the outside contractors have made on the jobs. A specific application of arc welding is in the making of high-speed tools, a piece of the tool being made of ordinary steel while high-speed tool steel is used for the cutting edge only. Some of the various applications are as follows:

Building-up of worn wearing parts, pins, rollers, bearings, etc.; welding of plates in lieu of riveting, or where seams are leaking; building up of rivets; building up of stripped gears; repair of cracked castings; making of high-speed tools; filling blow holes.

In manufacturing work: Welding of heads on tanks; welding of tubes in tube sheets; welding of feet and end frames, etc.

Brass, bronzes, and aluminum as well as steel, cast steel, wrought iron and cast iron can be welded, but none of the demonstrators have been able as yet to get very high tensile strength on naval brass.

Electric-arc welding is considered especially applicable for use on shipboard for emergency repairs of all sorts. In this connection it may be noted that the British cruiser Glasgow put into Rio de Janeiro after the battle off Chile with several holes below or near the water line, and was able, with the arc-welding set which happened to be in Rio de Janeiro, to weld plates over the holes inside of 24 hours and put to sea, taking with her the arc-welding set.

STEADY RESTS

By H. W. Dunbar.

WAY back in the early development of grinding, perhaps 25 or 30 years ago, when very light, narrow faced wheels were used and work was ground by polishing off the surface with very light cuts, no water was used to cool the work and steadyrests were unknown. Trouble arose on a particular job which was about 7 in. or 8 in. long and perhaps 5-16 in. in diameter, because the vibrations in this piece caused the wheel to make marks parallel to the axis of the work. These marks were considered imperfections, and they were imperfections because they could not be seen with the naked eye or without lapping the work in a hole, and seen prominently a great distance away. To these little marks were given the name of "chatters."

For a while they were overcome by changing wheels, getting different bond, different combination of grain and grade, or a different diameter of wheel which caused a different speed and a different cutting action, but this was a long and tedious operation; perhaps a number of wheels would have to be tried before a correct one would be found.

Origin of the Steadyrest

The parts being ground were needle bars used in sewing machines. They moved up and down many times a minute in the head of the machine. This rubbing naturally made these chatters more pronounced and it was very desirable to get rid of them; so a series of experiments was started by which it was hoped to eliminate this imperfection in the work. Among other experiments a spring which had a slight tension in it was placed on the revolving work. The spring was faced with leather where it rested on the work, the object being to absorb some of the vibrations in the work being ground, which it did, and with this the chatter marks were eliminated.

This was the origin of the first steadyrest as applied to grinding machines. The spring was very light and very simple in its construction, as is illustrated by Fig. 1. For a while but one of these springs was used; then one by one others were added until sometimes the entire length of the work was covered by a number of these little spring steadyrests. This gave

origin to the thought that the work while being ground must be steady to keep it from vibrating, for vibrations then were a source of trouble as everything was light, grinding not having developed to the point where it was looked upon as a commercial manufacturing operation where part after part must be ground, duplicating size with good finish, and all this in a reasonable time.

Steadyrest Development

As production increased and a variety of work required steadyresting, a rest was developed similar to that shown in diagrammatic

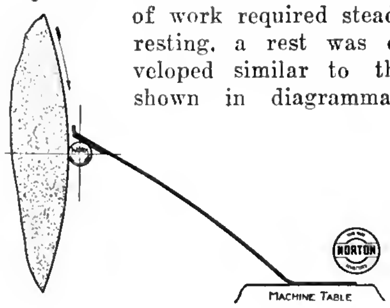


FIG. 1.

form in Fig. 2. This rest was more or less of a rigid construction; the floating shoe which rested against the work was contained in a casting and usually this form of rest travelled with the wheel and always stayed opposite the latter. As a matter of fact this rest has lived through the developments in the grinding industry and is used now by some grinding machine manufacturers for certain kinds of work. Usually, as above stated, this rest travelled with the wheel, but sometimes it was used as a fixture on the table and remained in this fixed location.

It was always felt back in the early days of the development of grinding that to steady the work it was necessary to have a spring rest which would yield as the work being ground happened to be out of line or out of truth. When it was suggested that a solid, rigid, fixed rest would grind round work, the person who advanced the thought was ridiculed, but

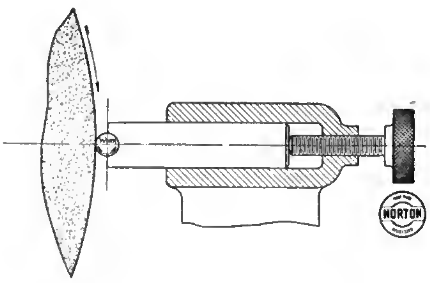

FIG. 2.

being of a determined nature and having a disposition which would not admit of defeat, the person in question developed and designed a rest as illustrated in Fig. 3. This simply shows the principles of the construction and, with his usual care and forethought, he so designed the rest that it could be of a spring type or of a rigid type by simply tightening down on the nuts and taking all of the tension out of the springs provided for this purpose.

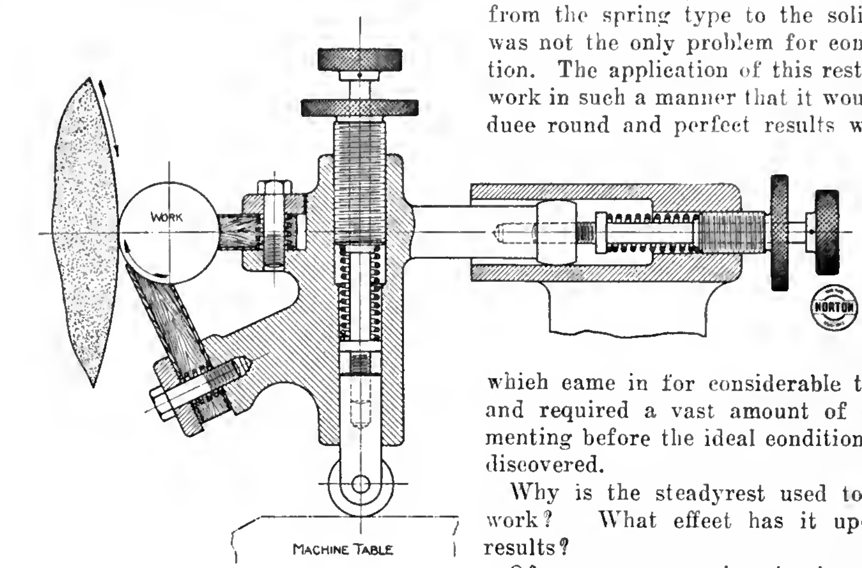

FIG. 3.

With this, round work, better work and more work was ground.

It gave way to a desire on the part of the inventor to produce a heavy type of rigid rest to be used with the heavy manufacturing grinding machine, then in its infancy, with which could be produced quantities of work perfectly round and with perfect finish. Such a machine was developed which did produce more work, and with it came the return of the old chatters. Coarser wheels were used, many work speed changes were provided, and rigid rests, illustrated in diagrammatic form by Fig. 4, were design-

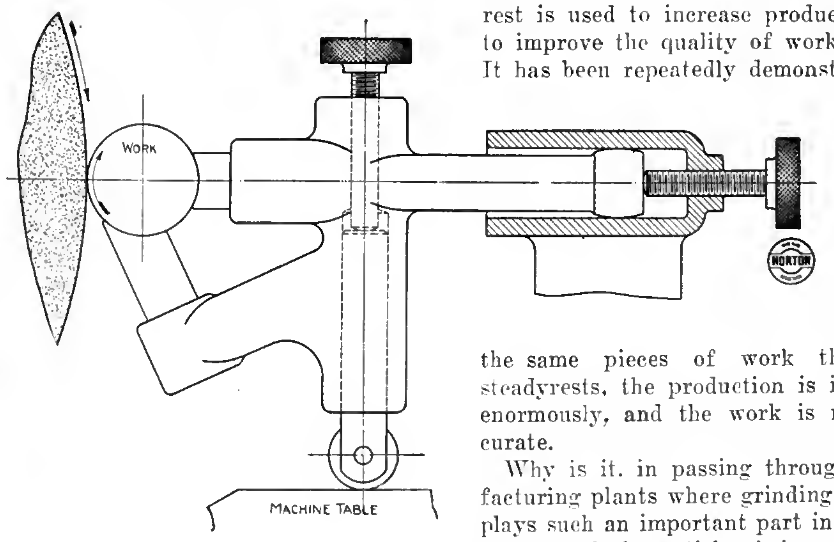

FIG. 4.

ed, which overcame the chatters difficulties.

Thus can be traced up to the present time the origin and development of steadyrests for supporting work while grinding, and with this development came increased production, until to-day the grinding operation is looked upon as one to be reckoned with in manufacturing processes.

The development of the steadyrest from the spring type to the solid type was not the only problem for consideration. The application of this rest to the work in such a manner that it would produce round and perfect results was one which came in for considerable thought and required a vast amount of experimenting before the ideal conditions were discovered.

Why is the steadyrest used to grind work? What effect has it upon the results?

Of course, one can imagine in a grinding machine, a long, slim piece of work which is not stiff enough to support itself and maintain a straight line in front of the grinding wheel. In such work the steadyrests are used to support it, to hold the axis of the work in a true line before the grinding wheel, so that it will be ground round. Without the steadyrest it would be impossible to grind such a piece of work.

Steadyrests Increase Production.

On other work which is stiff enough to support its own weight, the steadyrest is used to prevent the work from vibrating, but most important of all, the steadyrest is used to increase production and to improve the quality of work ground. It has been repeatedly demonstrated on the same pieces of work that, with steadyrests, the production is increased enormously, and the work is more accurate.

Why is it, in passing through manufacturing plants where grinding machine plays such an important part in the production of the articles being manufactured, that one sees the steadyrests discarded, lying under the benches, and the operator going along, unconcerned, grinding without them? If they would only realize that by putting them into use their output would be increased, their work could be brought to size more readily, and with all would come the natural reward for increased production

and better quality — more pay to the operator.

The real object of this article is to impress upon the users of grinding machines the importance of using steadyrests on their work and the possibilities in their use by the increased production and better quality, by explaining the principles of use.

Getting Results

Now to produce the best results, how should the steadyrests be applied to the work? Where should the shoes bear to give the best results?

In Figs. 5-10 in diagrammatic form are illustrated different types of shoes used in different types of steadyrests by different grinding machine manufacturers and the principles of their use will be described.

Let us assume to begin with that the shoes are all of the hardened steel type. In Fig. 5 with the V-type or wedge shoe, assuming the work to be irregular in shape (and all work is more or less this way as it comes to the grinding machine

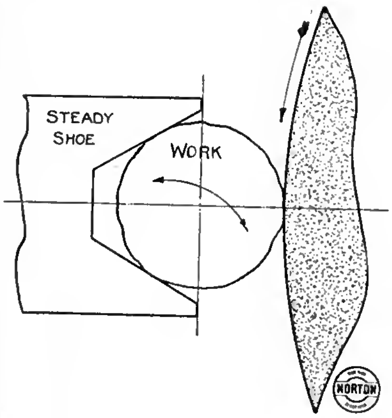

FIG. 5.

—that is why we grind it), we have exaggerated these irregularities by showing the work by a wavy line. Apply the shoe as shown in Fig. 5, and what is the result as the work revolves? When the little low spots or high spots come to the point of contact on the lower side of the wedge, naturally the work changes its position and drops or rises as the case may be. A corresponding change in position takes place when these same spots touch the upper part of the wedge in the steady shoe.

With the work rising and falling in this manner, caused by its own revolution, it naturally follows that the same motion takes place at the point where the work meets the grinding wheel and if you were to continue to grind forever, this work could never be ground round. When we say round we mean round to the point of commercial perfection, within a variation of say .0001 inch. Put the micrometer on the work at different points around its diameter and you will find a variation in roundness, the only improvement being in the finish.

The arrows indicated on the work show

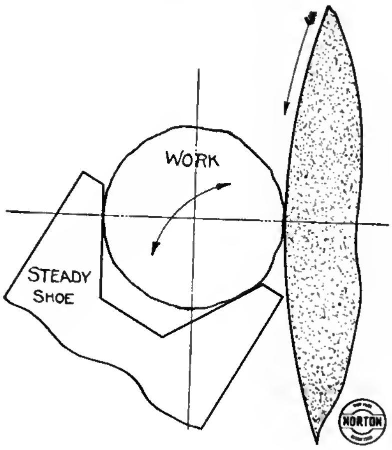

FIG. 6.

approximately the path that the work takes as it goes through this change in position, the motion being generally in the direction of the rise and fall, and determined by the point of contact on the shoe, which forms the fulcrum for it to swing upon.

In Fig. 6 we have simply changed the support with the thought that perhaps the weight of the work would be downward and the support must necessarily be underneath. The conditions, however, have not been changed. The irregularities in the work cause the same motion, but in a different direction, as illustrated by the arrows on the work.

In Fig. 7 we have assumed that the work is stiff enough to support itself, and have simply added a steady shoe diametrically opposite the wheel, with the thought of takin gthe thrust of the wheel or the pressure as it is grinding. Still the same phenomenon exists, and the irregularities in the work allow it to go and come between the wheel rise and fall, and the work cannot be ground round.

To prevent the work dropping (in Fig. 8), a shoe has been placed on two dia-

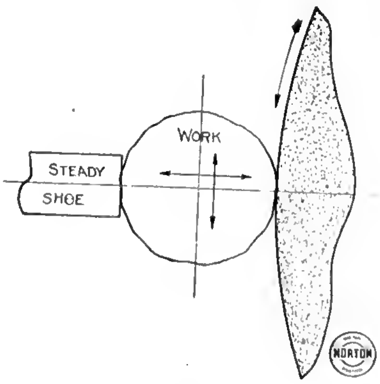

FIG. 7.

meters of the work—one the horizontal centre line, and one the vertical centre line. Still the work cannot be ground round. The little high and low spots still get in their bad work and the wheel follows the movement of the work and continues to keep it out of line.

Fig. 9 is a common shoe used in twist drill grinding. It is evident that the same law is at work, and the same results will be brought about.

Fig. 10, however, illustrates the only correct way of applying a steadyrest shoe to the work. It takes the form of a saddle. Here the arcs are long enough to span over the irregularities in the circumference of the work, and support it

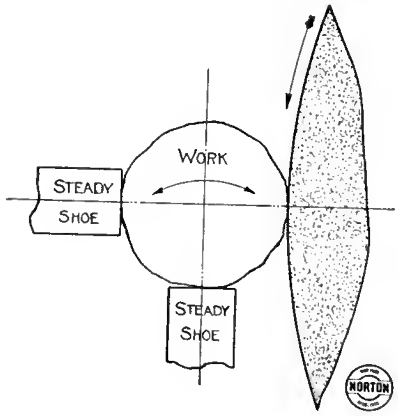

FIG. 8.

in its rotation, keeping its axis in a straight line all of the time, and the correct relation to the wheel, so that eventually the high spots are ground off, and the round, true work seats itself in

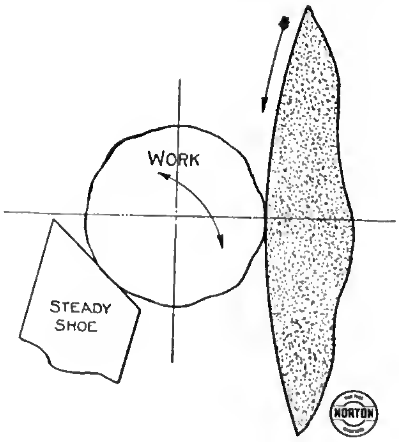

FIG. 9.

the shoe. The shoe generally is of the finished diameter of the work, so that it forms an accurate bearing for the finish cut.

One arc or saddle must be diametrically opposite the wheel to take the thrust of the wheel in that direction. The other saddle must be brought up as near as possible to the point of grinding, and on the opposite side of the vertical centre line to the first mentioned saddle. This takes the thrust of the wheel in its direction of rotation. If this arc is not positioned as described, but is placed even on the vertical centre line, the wheel

seems to draw the work in towards it and pinches and wedges it between wheel and shoes, so naturally the work will not come out round.

Steadyfast Shoe Materials

We see a number of different kinds of

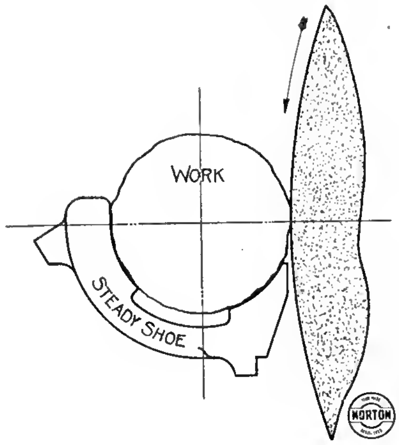

FIG. 10.

material used for steadyrest shoes, and the question is asked: "What are the virtues or what are the reasons for different kinds of material?"

We have, for instance, wooden shoes, bronze shoes, or hardened steel shoes, all

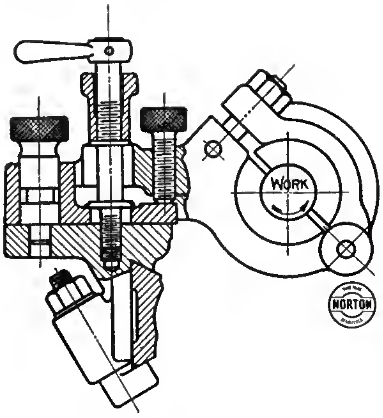

FIG. 11.

of which are equally good for producing correct work, but the hardened steel shoe has a decided advantage over the other types of shoes which are made of softer material and is always used where piece

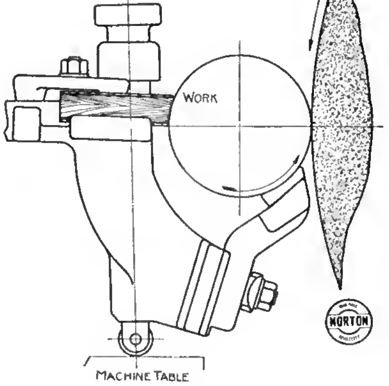

FIG. 12.

after piece must be produced, without thought or care on the part of the operator, to a given diameter and dimension. It naturally follows that a hardened steel shoe would serve best for this purpose because it does not wear so rapidly. With the softer materials, the wood or the bronze, the wear takes place very rapidly, and constant adjustments must be made to produce a duplication of parts to the same dimension.

Where the work is heavy and needs

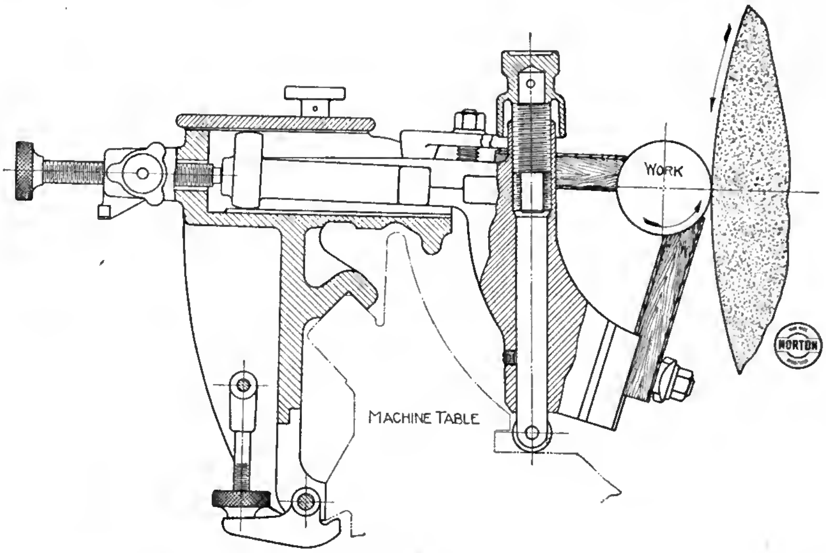

FIG. 13.

but little support, simply something to prevent vibrations, steadyrests with wooden shoes give good results, but it must always be borne in mind that where the shoes rest on the work, whether they be of wood, bronze or hardened steel, they must form an arc or saddle to span over a considerable amount of the cir-

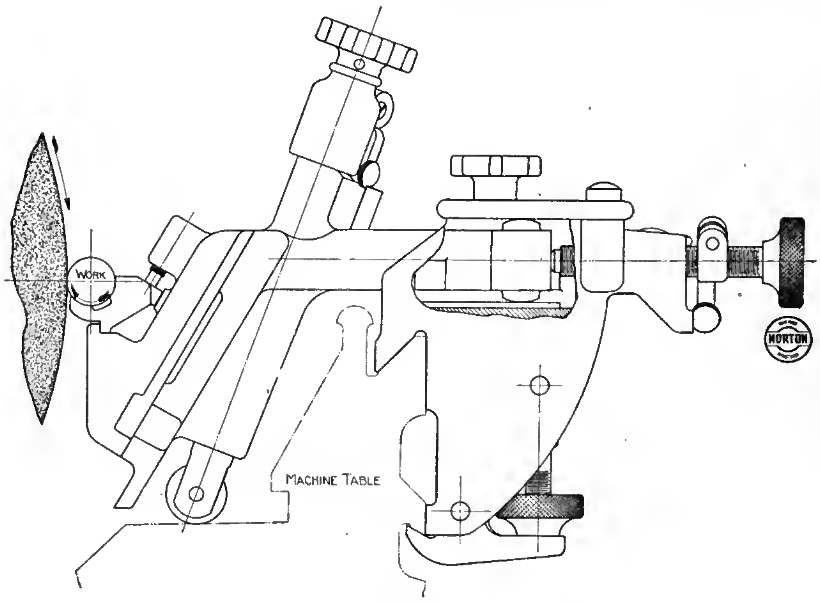

FIG. 14.

cumference of the work and act much in the same manner as would be the case were you holding the work up against the wheel with your hands, resting it in the palms.

It has always been felt that hardened steel shoes marred the work, but experience shows this is not true. Hardened steel shoes mar the work less than wooden shoes or bronze shoes, for the reason that, to begin with, they are polished out smooth and true, and the very fact that they are hard will not permit them to hold dirt or grit with which the work could be marred, whereas, on the other hand, the softer materials will naturally collect the dirt and grit and scratch or mar the work where they bear on it.

Steadyrest Types

Different types of steadyrests which are used successfully are illustrated in Figs. 11-14. Fig. 11 is the enclosed type of steadyrest and is used principally in grinding camshafts. Of course, with this closed type of steadyrest goes a longer time for removing or putting in the work, but, where exceptionally nice work is required, extra precautions must be used to bring about such results. Here the

work has much the same action as it does in the mechanism it is to be used with. The steadyrests form the bearings that the part being ground revolves in. They cannot be used, however, at the point where the work is being ground and must be placed at a point previously ground.

Figs. 12 and 13 are the common, plain-type wood shoe rests, Fig. 12 being adapted to large diameter work with an extension shoe.

Fig. 14 is a steadyrest carrying the hardened steel work shoe. The design, application and use are self-explanatory.

Just a word of caution. Too many steadyrests cannot be used. It is very easy to get too few. Even though there be no advantage in more steadyrests than necessary, there can be no harm. No rules can be laid down, no laws applied by which one can decide on the exact number of steadyrests necessary to support or steady work while grinding. Experience alone can be the only means of determining this question. Put on as many steadyrests as are necessary to support the work, to grind it round and true and to the desired finish.

Where duplication of work to a given dimension is desired, use the hardened steel work shoes and whatever type of shoe is used, always be certain that one support is diametrically opposite the wheel and the other is on the opposite side of the vertical centre line, as close up to the point of contact between the work and wheel as is possible to get it,

THE WORK PROPERLY SUPPORTED.

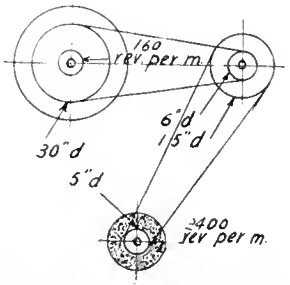
and further, be sure that where these shoes bear on the work they form arcs or saddles which span over a considerable part of the circumference of the work.

It may seem a hardship, and it may be considered unnecessary by some to use steadyrests, but, if you wish to increase production and get all that is possible out of the machine in the way of a number of parts an hour or day to a degree of accuracy and finish which borders on perfection, use steadyrests.

We are indebted to the Norton Grinding Co. for the data and cuts.

Questions and Answers

Question.—We have an emery wheel which calls for a speed of 2,400 revs. per minute. The pulley on the machine is 5 in. in diameter, and the counter-shaft has pulleys of 15 in. and 6 in. What size pulley must we use on the line-shaft which revolves at 160 revs. per minute?—J. H.



SPEED OF EMERY WHEEL.

Answer.—The speed of the line-shaft multiplied by the diameters of all the driving pulleys must equal the speed of emery wheel shaft multiplied by all the driven shafts.

Let x represent the required quantity, or diameter of pulley on line-shaft: then $160 \times x \times 15$ must equal $2400 \times 6 \times 5$, or to find the value of x, we have

$$x = \frac{2400 \times 6 \times 5}{160 \times 15} = 30 \text{ in., diameter of}$$

pulley necessary to put on line-shaft.

It would possibly be better to use a little larger pulley on the counter-shaft and a little smaller on the line-shaft.

* * *

Question.—Is there any material difference between an arbor and a mandrel?—P. E. T.

Answer.—Generally speaking, a mandrel is employed for holding work to be turned, while an arbor is a shaft for holding cutters, saws, etc., such as is used on millers, saws and similar machines.

* * *

Question.—We have several small tanks to construct which are to contain 30 gallons. They must go into a space of 18 by 20 inches; what must be their heaight?—A. B. C.

Answer.—As there are 277.25 cubic inches in one Imperial gallon, the tanks will have a volume of $277.25 \times 30 = 8317.5$ cu. in. As the tank must rest in a space of 18 x 20 inches, the area of base will be 360 sq. in. The height will therefore equal the volume divided by the base, or $8317.5 \div 360 = 23\frac{1}{8}$ inches high, nearly.

Question.—(a)—When two pipes, of 8 inches diameter and 12 inches diameter respectively, join into one, what must be the diameter of the main pipe to retain the same volume per running foot as the two smaller pipes?

(b)—Is there any general rule that can be employed for the solution of this and similar problems?—L. M. K.

Answer.—(a)—The area of the 8-in. pipe would be $d^2 \times .7854 = 8 \times 8 \times .7854 = 50.2656$ sq. in.

Area of 12-inch pipe $= d^2 \times .7854 = 12 \times 12.7854 = 113.0976$ sq. in.

Area of main pipe will be $50.2656 + 113.0976 = 163.3632$ sq. in.

$$\text{Diameter of main pipe} = d = \sqrt{\frac{A}{.7854}} = \sqrt{208} = 14.422 \text{ inches.}$$

(b)—The areas of squares or circles vary as the square of their sides or diameter; thus, a square whose side is 12 inches is 4 times as large as one whose side is 6 inches; see Fig. 1. This rule applies to the circle as seen in Fig. 2, where a circle of 12 in. is shown to be 16 times as large in area as a 3-in. circle. The area of the 12-in. circle $= 12 \times 12 \times .7854 = 113.0976$ sq. in., and that of 3-in. circle $= 3 \times 3 \times .7854 = 7.0686$ sq. in. The content of the former, 113.0976 divided by 7.0686, the content of the latter = 16.

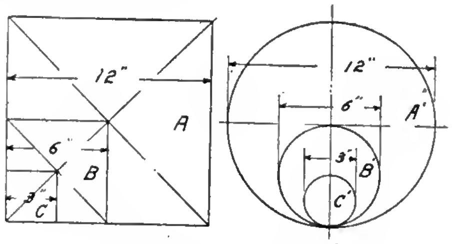


FIG. 1. FIG. 2.
PIPE VOLUMES.

As problems of this nature are usually solved by the right triangular method, where the square of the hypotenuse equals the sum of the squares of the two sides, a very convenient method and fairly accurate is that which uses the ordinary carpenter's two-foot square, and shown in Fig. 3. The diameter of one pipe is laid off on the butt and the diameter of the other on the blade. The

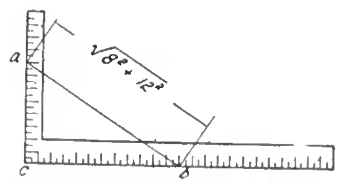

FIG. 3. PIPE VOLUMES.

distance from one extreme to the other, as a—b, will equal the diameter of the main pipe, which will have the same area as the two larger pipes. If three pipes are required to run into one, this prin-

ciple can be extended by taking the length a—b and using it as one diameter, and the third pipe diameter (b—d) as the two sides of another right triangle; the hypotenuse (a—d) will then equal the diameter of pipe required, Fig. 4. This method can be extended for any number of pipes.

* * *

Question.—When shrinking on several small iron collars some time ago we had trouble in keeping them tight, or due to them breaking. Is there any method

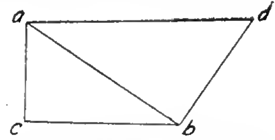

FIG. 4. PIPE VOLUMES.

whereby we might overcome these occurrences?—H. E.

Answer.—If the collars are small in diameter in relation to the shaft, it might be advisable to turn them from the solid, but, if this cannot be done, you might try knurling or scoring the shaft where the collar is to be fitted. By this means, the collar in shrinking will be forced into the impressions made by the knurl, and prevent it from slipping or coming loose.

GIRL WORKERS IN MUNITIONS' FACTORIES

THE rapidity with which the Minister of Munitions has organized numerous local arsenals in Britain has accentuated the shortage of skilled labor caused by the mistake made in allowing large numbers of skilled artisans to join the colors in line regiments, where their individual efforts could not have such far-reaching effect on the progress of the war as if they had remained at home to make the shells and fuses.

For some time women workers have been employed in a few engineering factories engaged in shell making, the first attempts being largely in the nature of experiment. The results of these efforts have been so successful that the entrance of women into this field of patriotic effort is increasing rapidly.

Those who are familiar with the general capabilities of machine tools are quite astonished at the results already accomplished, according to a report in "The Engineer." The girls employed were entirely new to the work, but so great was their enthusiasm that they soon became adepts in operating the various machines. Not only have they become skilful enough to produce work true to gauge, but the average output is quite high.

In a recent visit to the Glasgow factories organized by Sir William Beardmore, an opportunity was afforded of observing the conditions and work. About 800 girls are at present employed in these plants, the particular plant visited employing over 300 alone.

Girls Develop Skill

Along with these 300 girls are 60 men who are employed in tool-making, setting up machines, laboring, tightening up base-plates, and other work which requires considerable strength rather than skill. Some of the girls have now been at work for about four months, and were first trained by special instructors selected from men employed in other departments of Messrs. Beardmore's works, assisted by skilled operators sent by the makers of the machines, and after only a few weeks' instruction were found capable of a good output on many operations.

Every encouragement is offered to them, and the greatest attention is paid to their health and comfort. Lady superintendents are in charge of the place day and night to look after the girls, a good mess-room is provided for their meals, and a 15-minute interval for tea is allowed during the afternoon. The result is an extraordinary appearance of keenness and contentment, and whether done by day or night, the work is just as good and just as speedy.

The girls will not admit that the work is too heavy for them and one cannot but admire the manner in which they handle 4.5-in. shell bodies without mechanical appliances or assistance from the laborers provided by the company.

TORONTO HARBOR DEVELOPMENT

OVER two million dollars has been spent on the harbor improvement work this and last year. The great development plan, including sea wall, boulevard, parks and industrial areas, which will take until 1921 to complete, although interrupted this year by the discovery of defects in the Government work, has been going ahead apace. The Harbor Commission has not let up in its part of the work, and a great area has been reclaimed by the dredges. About 200 acres of land, valued at $10,000 an acre, has been made in the industrial district, a total value of $2,000,000, which cost $450,000.

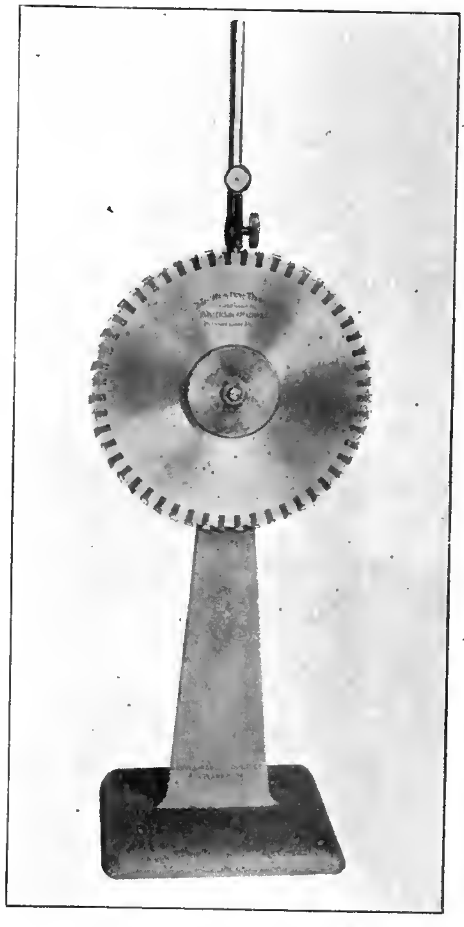
Making Land

Two big dredges are now operating, one in the Ashbridge's Bay district, the other in the west end near the Humber, and since spring they have pumped 2,200,000 yards of material. Clam-shell dredges are working in the vicinity of Leslie street, throwing up large earthen dykes to retain the filling. Twenty-five acres have been made in the west since the spring, and between 75 and 100 acres in the east. At Ward's Island, 15 acres of park land has been made for the city. No crib-work has been done this year.

The special commission appointed by the Government to inspect the Government work which was found defective is still on the job, and has eight divers engaged. The Canadian Stewart Co. have been given 100-foot sections to shown what they can do to make good the work about which complaint was made. The repair work will take considerable time, and a year's delay is the consequence.

SETTING DEVICE FOR INSERTED TOOTH SAWS

TO enable the teeth of inserted tooth saw blades to be set accurately to the proper height and thus all do their proportionate share of the work, the Hunter Saw & Machine Co., Pittsburgh, Pa., has placed a special device on the market. It has a cast iron base into which is fitted a cold-rolled steel bar. A graduated indicator slides up and down along the bar and is adjusted to permit blades up to a maximum diameter of 76 in. to be assembled rapidly and correctly. In connection with the device the proper size of arbor is furnished to fit blades from 12 to 76 in. in diameter.



SETTING DEVICE FOR INSESRTED TOOTH SAWS.

Accuracy in the setting is taken out of the hands of the mechanic and left to the indicator at the top of the blade, which indicator registers to 0.001 in.

CONTEMPORARY WAR ARTICLES

Embracing Information and Data Drawn from a Variety of Sources Relative to and Arising from the Prosecution of this Many-Sided European War

MODERN MUNITIONS OF WAR

IN the third and last of his lectures on the subject "Modern Munitions of War," at the Royal Society of Arts, on Wednesday, Professor V. B. Lewis discussed poison gases and bombs. Gases, he said, could be divided into three clases. In the first class were those which produced death, but had no poisonous effect. They killed by merely cutting off the oxygen supply necessary for life. Carbon, dioxide, nitrogen, and hydrogen were gases of this character, and were what might be termed suffocating gases.

In the second class were the true poison gases, which included carbon monoxide, cyanogen, and several others, 1 per cent. of which in the atmosphere would rapidly prove fatal. They were purely toxic in action and nothing else.

The third class consisted of asphyxiating gases, and included sulphur, dioxide, chlorine, some oxides of nitrogen, and that curious gas called phosgene. These had an effect upon the respiratory organs which produced spasms in the throat and set up such virulent inflammation of the respiratory organs that death ensued. It was these latter gases, or some of them, that the Germans had undoubtedly been using.

Poisonous Gases in Warfare.

As a matter of fact, continued Professor Lewis, it was not an easy thing to use a poison gas in warfare. Many people supposed that carbon monoxide was used as a poison gas in warfare, but a little consideration showed the fallacy of this idea. As a matter of fact, more carbon monoxide had been produced by the ordinary propellants used by ourselves and our enemies than we could have made had we set out to make this gas. The shells used in the 15-in. guns on our super-dreadnoughts, which contained 400 lbs. of cordite, gave, roughly, 2,500 cubic feet of carbon monoxide, and the gas was given off in every form of explosive used. Nevertheless, not one death could be directly traced to carbon monoxide, with the exception that during the sieges of Liege and Namur there were one or two cases of death in forts where the shells had penetrated before they burst.

The reason of the immunity was the wonderful power of gases of diffusing and intermingling against the force of gravity. Professor Lewes showed two experiments demonstrating this, and proving Graham's well-known law that gases intermingle at a rate which is inversely proportional to the square root of their density. In order, therefore, to obtain an asphyxiating gas which would not diffuse before it reached the opposite trenches under the influence of light air currents it was necessary to have one much heavier than air. For a gas to travel in a light air current it must be at least double the weight of atmospheric air. This limited the gases which could be employed, i.e., asphyxiating gases, to the following:—

	Density	Times heavier than air
Sulphur dioxide	32	2.21
Nitrogen tetroxide	46	3.17
Chlorine	35.5	2.46
Bromine vapor	80	5.36
Phosgene	50.6	3.49

Asphyxiating Gas Production—Sulphur Di-oxide.

Professor Lewes had samples of these gases on the lecture table and explained briefly the manner in which they are made. Sulphur dioxide was one of the earliest gases thought of for use in warfare. It is nearly one hundred years ago that an ancestor of the present Earl of Dundonald suggested the use of large stacks of easily burnable material which would give off great volumes of smoke which were to be fed by sulphur. These were to be built to the windward of the enemy, so that the smoke blew towards him, and under cover of the smoke an attack could be made.

The British Government at once declined to have anything whatever to do with the scheme; it had been suggested again and again at various intervals, but on each occasion it had been turned down with abhorrence. At the beginning of the present war it was again suggested and again declined. Sulphur dioxide, converted into a liquid state, was being used by the enemy in hand grenades, and with it were used a number of volatile substances of a disagreeable and poisonous character to give a little extra "bite" to the sulphur dioxide. As a gas, however, it was comparatively harmless, because if one could escape from the neighborhood it would be found that the effects passed away after a time and there was no lasting injury.

Chlorine Gas.

The second in the list—chlorine—was undoubtedly used by the Germans to the largest extent. This was made simply and readily by heating a mixture of hydrochloric acid and black oxide of manganese. It was a yellow gas and 0.04 per cent. mixed with the air made the surrounding atmosphere irrespirable and its effect upon the lung tissue was such that, inhaled in anything like large quantities, there was practically no recovery from it.

Chlorine is made in large quantities electrolytically at several large chemical works in the neighborhool of Widnes, and can be made into a bleaching powder or condensed into a liquid state and bottled in steel cylinders lined with lead. In Germany enormous quantities were made and bottled in this way, and it had been used in South Africa and other places for the treatment of gold residues, i.e., for treatment of some of the poorer slags, and now this gas was largely used in the war by the Germans.

The use, however, of chlorine gas in this way under such great pressure is not entirely without trouble, because when such a liquefied gas is liberated and once more assumes a gaseous form there is such an enormous amount of heat absorbed that the surrounding conditions are made most uncomfortably cold. This was demonstrated by experiment. Thus, say, there were a dozen cylinders of gas in the enemy's trenches, it will be seen that so intense would be the cold produced on liberation of the gas that trouble would be experienced with the chlorine freezing in the tubes along the trenches. The result was the necessity for driving the gas out into a chamber sufficiently large to prevent cooling down to the point at which the chlorine would solidify, or else to blow the chlorine into a heated coil or tube which would do away with the absorption of heat.

It had been reported—he was not sure with what truth—that the enemy had at times placed pipes some 10 feet or 12 feet in advance of his trenches, fitted with valves connected with gasometers and a chlorine manufacturing plant in a wood or other convenient spot a short distance away. Then the gas had to be merely turned on and there was not the trouble of cooling through the change of state. With this gas there was such a corrosion of the lungs as to cause very rapid dilation of the heart, which proved fatal after a short space of time even if the victim were rescued from the position he was in.

Other Gases.

Another gas which the Germans were credited with using was bromine vapor. Bromine vapor was of a reddish-brown color, but as a marked feature of the German gas attacks had been the yellowish color of the cloud of gas, it was probable that in almost every case the gas

used was chlorine, or bromine vapor very much diluted.

Nitrogen tetroxide, one of the oxides of nitrogen, was another reddish-brown gas and also had a serious effect upon the lungs. The first effect was similar to chlorine, producing an acute form of bronchitis. A man might appear to be getting over the effects, but after he had apparently recovered he would have a sudden collapse and die, due to erosion of the lungs and air passages. There was not the least doubt in his mind, said Professor Lewes, that chlorine and sulphur dioxide were the gases the Germans were using; all the symptoms pointed to them, there being an absence of the deep yellow staining which would accompany the other gases in the list given above.

After briefly referring to respirators and recommending, as the most efficacious, a strip of flannel or cotton rag, soaked in ordinary washing soda, Prof. Lewes said it was an open question question as to whether we should retaliate. Many people believed we should, and if he thought we could thereby save one of our men he would be as strongly in favor of this as anyone. The Germans, however, expected retaliation and were prepared to the utmost for it. Nothing we could do would surprise them, and under these conditions it was far better, in his opinion, to keep our hands clean and fight that straight fight that had always pulled us through.

Bombs.

In conclusion, Professor Lewes drew attention to the difference between British and German bombs. There was not, he said, the slightest doubt of the superiority of English bombs over the foreign variety. Samples of the 10 lb. and 20 lb. bomb carried by aeroplanes were on view, and it was explained how for the destruction of life these were filled with 4 lb. of T.N.T., and shrapnel bullets, whilst for incendiary purposes the charge consisted of about 8 lb. of T.N.T. alone. The functions of the two sets of vanes were described, the fixed vanes being for the purpose of giving a perfectly straight downward path to the bomb, and the top revolving vane having for its object the setting into motion of the firing mechanism. Before releasing the bomb a safety pin is removed, which allows the revolving vane to move. Thus in ordinary handling there is complete safety, the firing mechanism not being in a position to operate until the small vane has revolved four and a-half times.

The British incendiary bombs Professor Lewes would not describe, "because they differ in construction from those of the enemy." As to the German bombs, two specimens, or rather remains, were shown of bombs dropped during the earliest East Coast raids. One was picked up at Braintree by two soldiers, who dropped it into a bucket of water, and in this connection it is interesting to note that the authorities state there has not yet been one incendiary bomb dropped here that could not be put out by a few buckets of water. Both bombs showed very rough workmanship mechanically, and seemed to indicate, as Professor Lewes said, that the Germans thought that any old thing would do. Their contents were a winding of tarred rope round a rough frame, inside which were a quantity of resinous bodies, and in the centre a heating charge of thermit, and below a tray containing amorphous phosphorus. The other relic of a bomb was obtained from the recent London raid and was of a similar character, although slightly different in shape from the Braintree sample.

Amorphous Phosphorus.

Amorphous phosphorus, continued the lecturer, seemed to be playing a rather important part at the front and was causing us some trouble. At a temperature of over 300 deg. amorphous phosphorus was converted into ordinary phosphorus and at once caught fire. The Germans were using this in shrapnel shells for marking the range at night. If a man was wounded by a piece of such a shrapnel phosphorus poisoning and complications were set up which were extremely difficult to get over. The Germans could secure their object by the use of harmless substances, but the devilry in their nature made them employ substances of this character, which caused intense suffering.

We are indebted to The Engineer for the foregoing abstract.

INSTRUMENTS USED ON AEROPLANES.

THE various instruments in use on aeroplanes would puzzle those who are not familiar with the work, says The Times, London, England. Nominally they are ordinary enough, but they must possess in many cases peculiarities of considerable importance. The list includes:—

1—Engine speed indicator.
2—Air speed indicator.
3—Horizontal (transverse) level indicator.
4—Gasoline gauge.
5—Aneroid graduated in feet height.
6—Oil gauge.
7—Aeroplane compass.

In addition to these are the bomb sight, the bomb release mechanism on some aeroplanes and in some the wireless equipment, none of which is it timely to discuss just now.

Engine Speed Indicator.

The engine-speed indicator being the rough gauge by which it is ascertained that the engine is pulling properly—since it is coupled to the approximately constant load of the air screw—must not only, like all aircraft instruments, be exceedingly light, but must possess an accuracy very much in excess of that of the more ordinary motor car speed indicator. For example, a 3 per cent. error arising without warning would be a grave matter.

If an engine intended to run at 1,150 revolutions per minute were, in fact, to be running only at 1,120 revolutions per minute, when the speed indicator declared 1,150, this would induce the attendants to suppose that the propeller was getting distorted and giving insufficient thrust. The result would be the delaying process of changing propellers.

Now, the mere moving about of the flexible driving shaft will often be found to make 3 per cent. difference in roughly constructed speed indicators. Another fault which is found is that of giving a speed reading when speed is rising different from that given when it is falling. This lag may in the extreme case endanger a pilot, apart from leading, as in the previous case, to unnecessary waste of time, owing to misleading information about the state of the engine.

It is not always recognized that when the instrument is exposed to the vibrations of an aeroplane, the readings are often different from those obtained in steady test. The test should, therefore, be made in such a way that moderate vibration can be applied. On a motor car a continual swing of the needle from say 23 to 26 miles per hour would be no grave defect, but in the air such a swing covers the percentage range of variation which is tolerable and, therefore, the reading is certainly not dead beat enough.

The problem is a difficult one, partly, because of the high engine speed used, in many cases up to 1,800 and 2,000 revolutions per minute—a very widely different matter from the road wheel speeds of cars—and partly because of the much greater importance attachable to the result; its solution, however, has been remarkably well obtained.

Level Indicator.

The level indicator is not always carried, and when carried is not always transverse as it should be. It is usually a small arched spirit level. The objection to carrying such a level fore and aft is that the readings are rendered even more fictitious and misleading in this position by the acceleration of the aeroplane. When the machine is flying dead level a fore-and-aft instrument will indicate a substantial gradient if the aeroplane be accelerated or retarded. In this position, therefore, it should be abandoned. When it is placed trans-

versely there are errors due to side gusts, but these are very much smaller and cannot lead to that great bugbear of the flyer, "stalling" the machine.

The purpose of the transverse spirit level is in part fulfilled by Mr. Ogilvie's floating "bit of string" hung clear of the intake or slip stream of the tractor air-screw, because any continuous banking without turning involves yawing, and therefore a side wind strikes the string. Were the string easily set clear of propeller disturbances and its indications more easily visible within the pilot's enclosure, especially at dusk, its universal use would be assured. It scarcely seems necessary to mention that the transverse spirit level shows "level" however steeply the aeroplane be banked, provided the bank is the dynamically correct one for the radius and speed of the turn.

The gasoline gauges for both level and pressure are by no means to be overlooked among the important, and indeed essential instruments on an aeroplane. Moreover, their installation offers several difficulties so considerable that they are not imperfectly met.

Regulating the Gasoline.

The volume of gasoline is so large nowadays that the use of a gravity flow as sole supply is practically out of the question (in view of the respective levels of carbureter and fuselage). The pressure feed tanks are often under the seat of the passenger, and as a loss of pressure must not result in a forced landing without plenty of warning, it is becoming universal to use a gravity supply of fuel from an auxiliary tank placed high up and containing one hour's supply or more. This tank is kept always full by permanent pressure on the main tanks.

The pilot wants to know this pressure, and a gauge for this is fitted. He wants to be certain that he is not over-pumping, else he merely forces gasoline to waste through the overflow from the top or gravity tank. The gravity tank must have access to the open air by this overflow pipe, otherwise fuel will not be supplied under gravity on just the very emergency arising from the loss of tank pressure. The fuel overflow from the upper or gravity tank might be made to advertise itself, but for the fact that it will blow back into the face of the pilot and temporarily blind him. This means a fuel level gauge in the upper tank.

All gauge glasses, reflex and others, are hard to read from the distances usual in practice owing to the white color or the liquid, and poor light at dusk, and other reasons. All dial gauges at present made involve complications, and are not usually fitted with mechanism for transmitting the information to the pilot cab. The main tank level gauge being under pressure is subject to the same difficulties. There are pneumatic transmission devices, which mostly suffer from grave errors due to the expansion of the enclosed air, with temperature or with the very large and rapid changes of altitude of an aeroplane. Moreover, all pipe work on aeroplanes has been proved difficult to maintain intact in view of vibration and distortion of the machine generally both in the air and by the shock of landing.

The Aneroid.

The aneroid is one of the instruments which has been perfected to a very remarkable degree by the advent of flying. Three years ago there existed no aneroid which did not suffer from the serious defect of a violently vibrating index needle, or alternatively of substantial inaccuracy from friction or damping under which the vibrations were masked. Much labor has been expended in getting the support of moving parts situated at the precise centre of gravity of these parts —an alteration which was never needed till an aneroid was required for accurate reading on a vibrating support. The balancing of those portions of the expanding boxes which may be regarded as moving parts is not entirely an easy task, but the solution exists. What does not exist is any means by which the flyer can tell whether the reading of the barometer has changed owing to atmospheric variations during the four or five hours since he left earth. Any error that arises in this way the flyer reads off, unwittingly thinking himself to be higher up or lower down than his real altitude. Here again the physicist may yet come to the rescue, so the problem is posed for his attack.

The Oil Gauge.

Even so small a matter as the oil gauge on the engine's oil circulation requires special care with some aeroplane engines. Thus, if the oil pressure is too high the engine uses an excess of oil and thus reduces the number of hours of air endurance; that is, it may involve a forced landing earlier than expected. Other engines are inclined to cause an excessive pressure at the time of starting, when the oil is cold and highly viscous. The pressure rises so high that the gauge either bursts, or, if it is strong enough to take the high pressure, is insufficiently sensitive to read at the low pressure of normal use with warmed oil.

The aeroplane compass must, after being installed, be swung so as to stimulate by small adjusting magnets the error due to permanent magnetism of steel parts, just as a ship's compass is swung. It must be corrected, if possible, to avoid quadrantal error from the effects of soft iron parts, such as tanks, which may be nearby. It must, far more particularly than a ship's compass, be corrected for the effects of vibration, which cause a very large deviation. It must also be capable of allowing a course to be steered direct north, and no swing should be caused by banking. These corrections will be seen to be substantially different from those required on board ship, and substantially more searching.

Illumination.

Lastly, the illumination of all instruments on aircraft is a peculiar problem. Luminous paint of all kinds is useless, because, however valuable this might be after dark has set in, no luminous paint has sufficient value to act adequately during the twilight, and it is precisely in twilight and not in the dark that the illumination is required. Electric lighting must be very carefully moderated to a minute light, else the contrast between a well-lighted intrument board and the poor light outside blinds the flyer, who, therefore, cannot safely alight or properly distinguish his objective.

STEEL FURNACES' RECORD OUTPUT

THE blast furnaces of the big steel interests made a new tonnage record in August, producing pig iron at the rate of 67,801 gross tons a day, against their previous high record of 64,658 tons a day, made in April, 1913. The production of steel probably represented a still greater gain over the previous record rate, for the reason that, when the previous record pig iron rate was attained, the steel works had been operating substantially at capacity for about eight months, and had undoubtedly consumed all their stocks of pig iron, whereas lately they have still had stocks from which to draw. On account of the filling of so many war orders requiring heavy cropping from the ingot 20 to 40 per cent., the production of steel ingots is doubtless greater, in proportion to pig iron, than ever before.

The merchant blast furnaces produced pig iron in August at the rate of 21,865 tons daily. While the merchant furnace production has been increasing since early in the year, by a total of fully 50 per cent., the August production was 23 per cent. under the previous record, which was 28,364 tons a day, made in February, 1913.

No factory owner of sense would expect one of his machines to run without lubrication, and decent people require the oil of fair treatment and pleasant words to keep them in good running order, as well as a reasonable remuneration.

TESTING THE EFFICIENCY OF LUBRICATION.*

By Alan Flowers.**

THE probability of being able to determine with great exactness the best lubricant for a specified group of conditions, is indicated in a recent paper by Professor Alan Flowers.

The apparatus as now constructed is the result of experiments begun at the University of Missouri in 1909. Fig. 1 is a diagrammatic illustration of the apparatus. It consists of a steam cylinder within which two pistons connected by a piston rod are placed. The space between the two pistons has a constant volume, so that steam admitted to this space does no work on the pistons. Two steam pipes are brought into the cylinder at points just short of the parts rubbed over by the piston, so that oil carried along by the steam may readily reach the rubbed surfaces. An electric motor drives five slots may have rings placed in them. All the rings have a ⅜-in. face and each of the four sets has a different radial thickness, so that the intensity of pressure exerted by the piston-rings against the cylinder wall may have values from 2 to 9 lb. per sq. in. Suitably located thermometers indicate the temperature of the working surfaces. Arrangements were provided so that the outer sides of the pistons could also be subjected to any desired steam pressure. The difference in pressure on the two sides of the piston is an important element in the amount of oil feed necessary and the difference in temperature on either side of a piston, as in condensing engines, is an important element in determining the viscosity of the lubricant, and therefore the amount of friction encountered by the pistons and piston-rings.

Electric heating coils provide a means of testing with various degrees of super- at atmospheric pressure, it takes at least 30 minutes for the friction to change.

Conclusions

The author deals with various features, and amongst other results presents the following conclusions:

Different lubricants do not necessarily give the same friction coefficient, and their lubricating value can be determined by means of this apparatus.

Constancy of friction requires a liberal supply of lubricant, particularly when there is a difference of steam pressure on the two sides of the piston.

Cutting off or reducing the supply of lubricant brings about an increase of friction within 5 min.

Increasing the supply of lubricant may bring about a reduction of friction within 15 min., but at low pressures, or when starting a run with surfaces free from oil, it may take two hours to reach a consistently low value of friction.

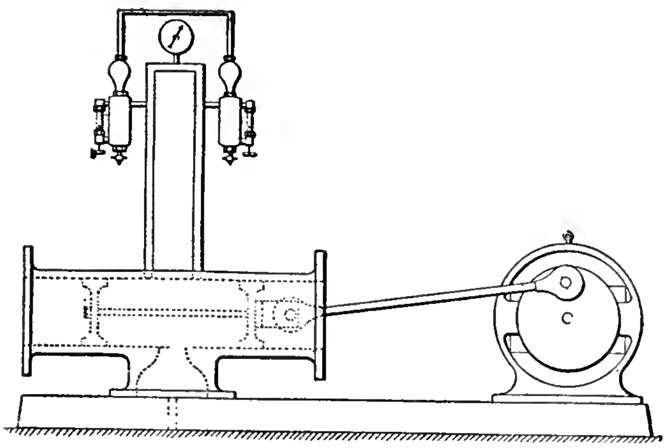


FIG. 1. DIAGRAM ILLUSTRATING PRINCIPLE OF CYLINDER FRICTION APPARATUS.

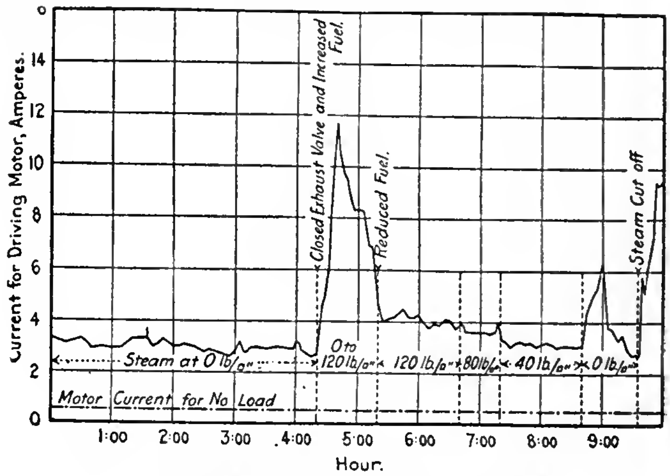

FIG. 2. READINGS AS TAKEN IN A TEST.

the two pistons by means of a crank disc and connecting-rod, and the net input of the motor is a direct measure of the friction of the two pistons and piston rings.

Full Size Apparatus

Actual dimensions of the apparatus are: Cylinder, 8-in. bore x 36-in. long, with a 3-in. drain from the middle of the bottom; connecting-rod 33 in. long, which with a stroke of 8 in. makes the maximum angularity of the connecting-rod less than 7 deg.

Ball bearings at each end of the rod make the connecting-rod friction negligible compared with the cylinder friction.

Two 1-pint. Detroit sight-feed lubricators supply oil in the usual manner to the steam pipes.

The piston-rings at present in use are of the constant-radial-thickness type. Each piston has five slots and one or all

*From a paper read at the recent annual meeting of American Society for Testing Materials.

**Professor of Electrical Engineering, Ohio StSate University, Columbus, Ohio.

heat. A set of readings is plotted in Fig. 2.

Peculiar Results

Variations observable in this test were largely due to the difficulty of controlling the oil feed. There was an excessive rise in friction amounting to 300-400 per cent. when the steam pressure was raised quickly from atmospheric pressure to 120 lb. per sq. in. This excessive friction does not occur when the steam pressure is increased gradually or when it is lowered; presumably it is caused by the sudden blowing of the oil out from the space between the piston-rings and the cylinder walls.

The effect of shutting off one of the two lubricators was to increase the friction within a few minutes, in spite of the fact that some oil was carried to the end at which the lubricator was shut off.

Shutting off all the lubricant caused an appreciable increase of friction within five minutes, when steam is present under pressure, but when steam is present

An increase in the rate of feed of the lubricant makes a considerable reduction in the friction when the amount fed is small, but with a continued increase of feed of lubricant, the friction tends to approach a certain minimum value.

The friction coefficients obtained so far are all large, 3 to 4 per cent. or more, and very much larger than the values found in well-lubricated bearings.

The friction coefficients obtained and the amount of lubricant necessary are greatly modified by the presence of steam pressure on the two sides of the piston.

The progressive employer is a firm believer in the fair-mindedness of average workmen, and believes it pays to take them fully into his confidence, and not only tell them what, but why. If we would all take the trouble to confide in and confer with our men freely and frankly, many of us would be surprised to find some hard-headed workman who can think just as fast as we can and who may have some good ideas in his stubborn head which it is up to us to get out.

ORDNANCE MAKING AS A CANADIAN INDUSTRY

THE demands which the future may have in store are the subject of much speculation and not a little misgiving by many of the numerous manufacturers who so promptly and efficiently transformed their peacetime factories into branch arsenals. When the call for shells was made, the manner in which Canadian manufacturers responded aroused considerable interest in the United States, and now when various firms in that country are getting down to a capacity basis on shell production they are frank in admitting their indebtedness to, and expressing their admiration for the many firms in Canada who so willingly placed all available information and experience at their disposal.

With a very few exceptions, our home manufacturers were engaged on contracts for the British War Office, while many of our neighbors were producing Russian ammunition. The strictness of British War Office requirements and the closeness of inspection, while somewhat irksome at times, were perhaps blessings in disguise, and demonstrated that our manufacturers are entitled to share first place with any other ammunition producers, whether British or foreign, Government or private.

The feeling of pride and satisfaction at being able to render patriotic service of such value has spread through all grades of producers; old men and boys have helped the cause in quite as effective a manner as if they had been eligible for enlistment, while many families who might otherwise have no direct interest in the war have been maintained in comfort as a result of their heads being engaged in shell making.

The impending decrease and the ultimate fading away of such a source of support will certainly go hard with many firms and individuals. Reports which continue to arrive regarding the unabated activity of the British Minister of Munitions are not calculated to have a very encouraging effect on producers here.

Despite desires to the contrary, the question which our shell makers are asking themselves is only intensified by the increasing activity of the Provincial Munitions Committees in Britain. Why, we feel constrained to ask should our manufacturers be left in the air, while Lloyd George continuously demands a doubling and trebling of the army of munition producers in Britain, an increase many times greater than the whole number of persons so employed in Canada?

The recent discussion regarding the proposed production of guns in this country may hold out hopes of continued activity to certain firms, but the efficiency of such a development as an aid in the war is very doubtful. In its economic aspect as a source of livelihood to a large proportion of the population it would be practically nil compared with shell production.

A gun and its projectile represent very clearly the two extremes of production methods.

Guns are costly. They are heavy. They require machine tools and other equipment for their production which by reason of their cost, and time required for installation, confine the possibilities of successful manufacture to a very limited number of firms. The cost of guns is not so much the amount of human labor due to numerous employees as the interest on vast plant expenditure. Wherefore then would the value of a large contract be of benefit to the country as a whole.

Shells are cheap. Their manufacture is second nature to Canadians. Their cost might be reduced by careful consideration, and the proportion of cost represented by wages is far and away greater than in guns. The actual total time that a shell is being worked on in machines may be measured almost in minutes, instead of days or weeks, as with a gun, while the individuals who share in the former time are at least ten as compared with one on gun making.

Ordnance making as a war-time industry will never benefit Canada to the extent supposed, and while it is hoped that with the successful accomplishment of "fixing," a call for further shell production may be issued, the time which must necessarily elapse in order to allow of the "fixing" catching upon production, is so great that many of our shell makers may well be pardoned for looking askance at the latest suggestion.

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., Sept. 20, 1915.—The continued demand from all quarters for war supplies and the optimistic feeling that in a short time this situation may further develop, keeps the industrial community as far as the war is concerned, moving at almost maximum activity.

Steel

The outstanding feature, as usual, is the demand for steel, this keeping the mills operating practically at capacity. While it was feared some months ago that the iron and steel industry might be affected to some extent by a possible shortage of labor, or that the demand would grow to such an extent that a shortage would occur in coke, pig iron, etc., at the present time the feeling generally expressed is that no serious restrictions will be placed on production for war supplies, particularly as the domestic situation in this direction shows little signs of returning to normal.

However, if the demand for steel for the manufacture of shells larger than those now being produced becomes general, which seems altogether probable, it will likely tax our mills to their very utmost, especially in the matter of billets, as the larger shells will be made from this class of product. There are indications that orders for large shells have already been received or are expected in the near future. Several plants are being equipped for the production of 6-inch shells and larger, one firm in Montreal hoping to start making the former in about a month.

Pig Iron

This market, while showing increased activity in some localities, generally remains stationary; quotations are practically the same as for the previous week.

Machine Tools and Supplies

The machinery market is little changed from that of last week. In some cases dealers are beginning to express the opinion that some difficulty may arise in securing suitable machines necessary for the production of large shells which from present indications are likely to be required. The machine tools that a large number of manufacturers have installed for the making of the smaller shells will be wholly inadequate for the production of the larger type, but those plants that have lately taken up the work of shell making and have installed somewhat heavier tools, not being able to get others in time, will be in a good position to accept orderes for the larger shells. This new feature in shell production will also create a demand for machine supplies in the way of special attachments. These in turn may develop some new features in tool design.

Metals

Metal quotations show little change, the situation keeping generally firm. Copper is slightly stronger in some directions, but other metals show a decline. The feature has been the jump in aluminum which is quoted at 50c per pound.

Very little change is to be noted in the price of old materials. However, owing to the rise in aluminum, the quotations in its scrap have correspondingly increased.

EQUIPMENT FOR AUSTRALIAN NAVAL DOCKYARD

D. H. Ross, Trade Commissioner at Melbourne, has cabled the Department of Trade and Commerce, Ottawa, to the effect that the tenders for the naval dockyards in Australia, which were detailed in our August 26 issue, have been extended to November 30. It was stated then that the tenders would close during the last week in October. As was mentioned also in the former article, the above mentioned tender forms have been received and may be inspected by interested Canadian manufacturers at the Department of Trade and Commerce, Ottawa. (Refer to File No. 1747.)

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

Toronto, Ont., Sept. 21.—There is little change to note in general business conditions. The gradual improvement in trade is being maintained and the volume of business is greater than it was for the corresponding period of last year. A better feeling prevails in business circles due to improved conditions and a better outlook for the future.

A new development in the engineering field is the proposal to manufacture artillery in Canada. Although this class of work requires considerable skill and is highly technical, the committee appointed by the Dominion Government has reported favorably on the possibility of making guns. The order is said to amount to sixty-five million dollars and the four grades of guns to be covered are the twelve-pounder, eighteen-pounder, 4.5-gun and the howitzer. Further developments have to be recorded in the munitions business. The Canadian Car & Foundry Co. have received another order for Russian shells worth, it is stated, over 50 million dollars. It is reported as being probable that a part of this order will be sub-let to Canadian concerns, the National Steel Car and Montreal Ammunition Co. being mentioned as probable participants.

Steel Market

The general situation in the steel trade is much the same as during the past few weeks, the brisk demand for forgings and rounds for shells continues, in addition to the big export business. There is such a big demand for steel for shells that Canadian mills cannot take care of all the business and inquiries have been sent to the States for 35,000 tons of steel rounds. The building trade is still very dull and there is little demand for structural shapes. Prices on bars, plates and shapes are unchanged but are holding very firm.

The improvement in the steel trade in the States continues and the situation is strong, particularly in open-hearth steel, for which there is a continued heavy demand. Prices on open-hearth products are very strong, and prices are almost certain to be higher. There is a continued heavy demand for rounds for shells and prices are holding very firm. A scarcity of wire rods is reported and quotations have advanced to $30, Pittsburgh. There is an active demand for billets and prices are firm the the advance announced last week.

Pig Iron

There is no change in the pig iron situation and conditions in the market continue much the same. Quotations on all brands are unchanged.

Scrap Metals

Prices of scrap metals, particularly copper, are firm, and heavy melting steel is strong. Fair business is reported and quotations are unchanged.

Machine Tools

Activity in the machine tool business

is not so much marked as a few weeks ago, and there is a lessening demand for new tools. Deliveries are still very backward, which is causing a more active demand for second-hand tools. The probability of further shell orders being distributed is interesting the trade, and a revival in business is anticipated shortly.

Supplies

Business continues brisk in machine shop supplies and prices are holding firm all round. The linseed oil market has re-acted and quotations are 2c higher, raw oil being quoted at 65c and boiled at 68c per gallon. Turpentine has also advanced 2c and is now quoted at 64c per Imperial gallon. Prices of leather belting are very firm and an active demand continues.

Metals

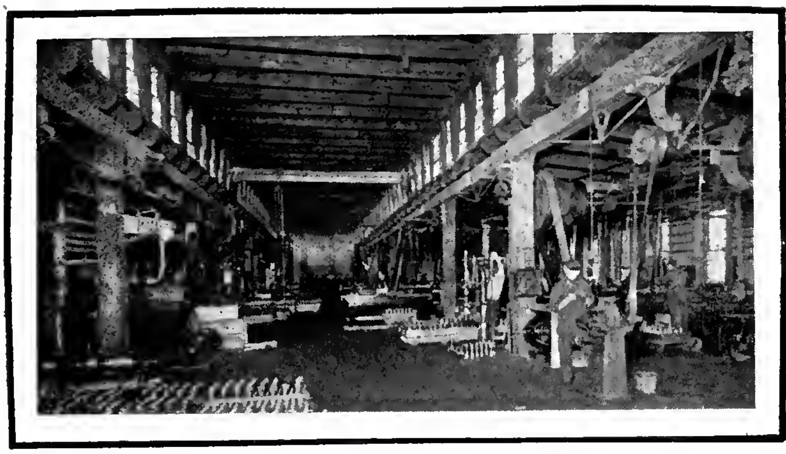
With the exception of a decline in antimony there are no price changes to note this week. The markets are steady at the lower levels recorded last week. As foreign exchange is intimately associated with the metal markets, the negotiations which are being conducted in New York between representatives of the British and French Governments and American bankers are naturally being followed closely by the trade. Both buyers and sellers are waiting developments and a rise in exchange will materially improve the prospects of doing business. There is some uncertainty in the tin market in New York as to how the new regulations imposed by the British Government will work out. The copper market is higher in London, but unchanged here, although the tone has improved. There has been more interest taken in the spelter market, but few sales have been made. The lead market is stagnant and prices unchanged. Antimony is easier because of a desire to reduce surplus stock, while aluminum is higher and quotations nominal.

Tin.—The market is dull, both in London and New York. There is very little inquiry for tin, both buyers and sellers are apparently awaiting developments regarding the loan which the representatives of the Allied Governments are negotiating in New York. Local quotations on tin are unchanged at 39c per pound.

Copper.—The British war loan negotiations are affecting the copper market but the outlook is brighter in anticipation of the loan being satisfactorily arranged. The market is firmer and quotations are unchanged at 19c per pound.

Spelter.—The market is quiet and unchanged. There is no disposition to cut the "Trust" price of 4.50 New York at present. Local quotations are unchanged at 6¼c per pound.

Antimony.—The market is quiet and



Shrapnel Shell Manufacture

In a Plant Producing Sheet Metal Working Machinery

Staff Article

The diversity of products formerly manufactured by what are now shell making establishments is perhaps only equalled by the originality and resource displayed in the methods invoked in the prosecution of the new industry. Dissimilarity between past and present activity has certainly had no deterrent effect on the continuity of successful operation which the plant described has always enjoyed, a fact which reflects credit on all concerned.

SHRAPNEL shell production has now attained such proportions that the detail description of its manufacture has become familiar to a large number of readers of mechanical and other papers; but, although the general cycle of operations in most establishments are similar to each other, the method of obtaining these results in the various plants differ to such an extent that a visit to the different factories impresses upon the observer the energies and resources employed and adopted by enterprising men to meet and overcome these problems with which they have been confronted.

The object of this article is not to describe the manufacture of shrapnel shells, but to show the means whereby some interesting and original methods were practised to eliminate and overcome obstacles that often become evident in cases of this kind where a new article must be produced from equipment intended for an entirely different product.

To describe these various methods, a brief outline of the different operations in this plant may be advisable.

After the rough forging has been marked for length, it is taken to the machine shown in Fig. 1. This tool (an old Hurlbut Rogers cutting-off machine) was practically in the scrap heap at the time, but was taken and remodeled as shown. The original friction drive from the front and rear was replaced by a powerful clutch drive from the end of the machine.

Roughing the Body.

Roughing the body was done on a Stevens & Co. $2\frac{1}{4}$ in. flat turret lathe, shown in Fig. 2. The shell is held on an expanding arbor and driven by the dog shown. A light cut is taken for a short distance, until the shell is supported from the rear with the two rolls shown in the cutter head. The feed is then thrown in and the rough cut taken. To put the round corner on the end of shell the cutter head, shown in Fig. 3, is used. The cutter (C) is securely held between two pieces (b) (b) in the head (d) and adjusted by the screw (a).

Roughing the Nose.

The fourth operation is the roughing of the nose and finishing the recess at the base of the shell for the powder cup.

This is also done on a Stevens $2\frac{1}{4}$ in. flat turret lathe. The shell is held in a special chuck designed in the shop, which proves very satisfactory. The details are shown in Fig. 4.

The casting A is bolted to a face plate on the spindle. The three section collet B is drawn in by means of the piece C, which is connected with a hand wheel at the rear of the lathe spindle by the rod D. The collet is kept expanded when released by means of the coil springs E.

Undercutting and Grooving.

The cutting of the groove, undercutting and waving are done on a Bertram lathe, with Bertram's waving and undercutting attachments. The waves are then nicked with a flat chisel to allow the air to escape when the copper band is pressed on; this also aids in preventing the band from turning when shell is leaving the gun.

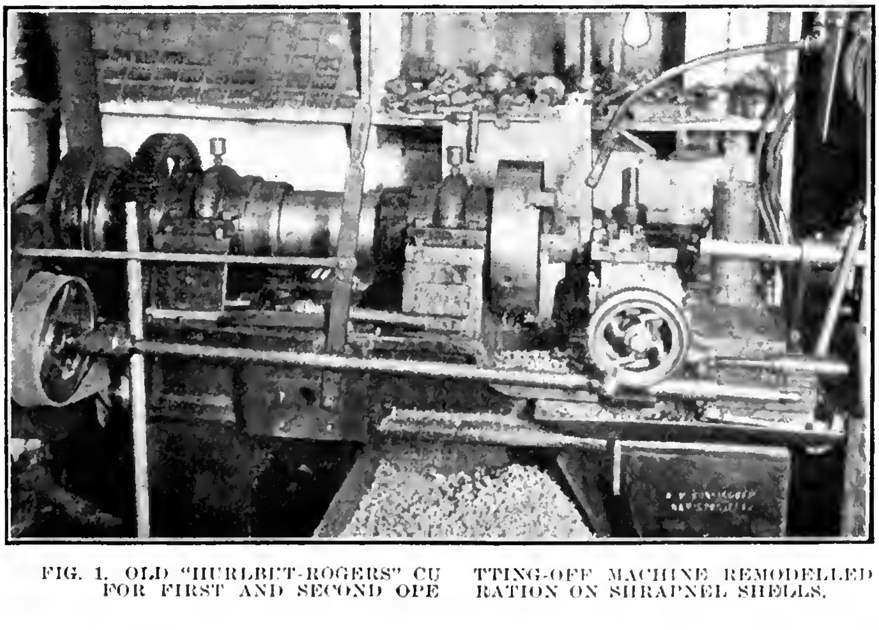


FIG. 1. OLD "HURLBUT-ROGERS" CUTTING-OFF MACHINE REMODELLED FOR FIRST AND SECOND OPERATION ON SHRAPNEL SHELLS.

Hardening and Nosing.

The shells are now heated in a natural gas furnace to a temperature of about 1,450° F. and hardened in a bath of special oil.

After buffing and testing with the scleroscope for the proper degree of hardness, which is about 45° on the graduated scale, they are re-heated in a special nose-heating furnace in a bath of

molten lead a short distance from the end and placed in a nosing press. Before the operation of nosing takes place the steel diaphragm is dropped in and the nose is then formed and placed in a box of lime to anneal for further machining.

Machining the Nose.

After annealing, the shells are taken to a Jones & Lamson flat turret and

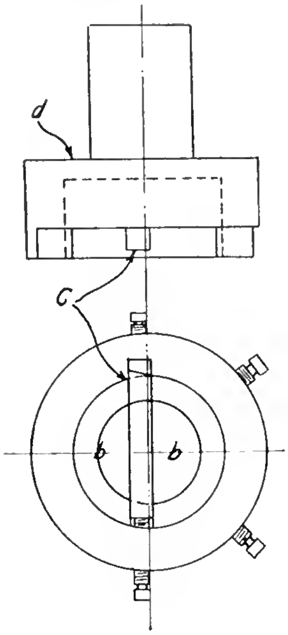

FIG. 3. RADIUS FORMING TOOL.

held in a chuck of the type shown in Fig. 4, and the nose rough-turned to the desired shape, faced, bored and undercut, and threaded for the fuse socket.

Grinding.

A centre plug is then screwed in the nose, and they are placed in a Ford Smith grinding machine and ground with a shaped wheel to the desired size of body and contour of nose.

While being ground the butt end of the shell is held in the chuck shown in Fig. 5. The piece of machine steel A is threaded internally to fit the lathe spindle and threaded outside to receive the nut B. This nut clamps the collet ring C (which is of 4 sections) upon the butt end of the shell. The spring D shown in the cross section of the ring at E for keeping section expanded when chuck is released.

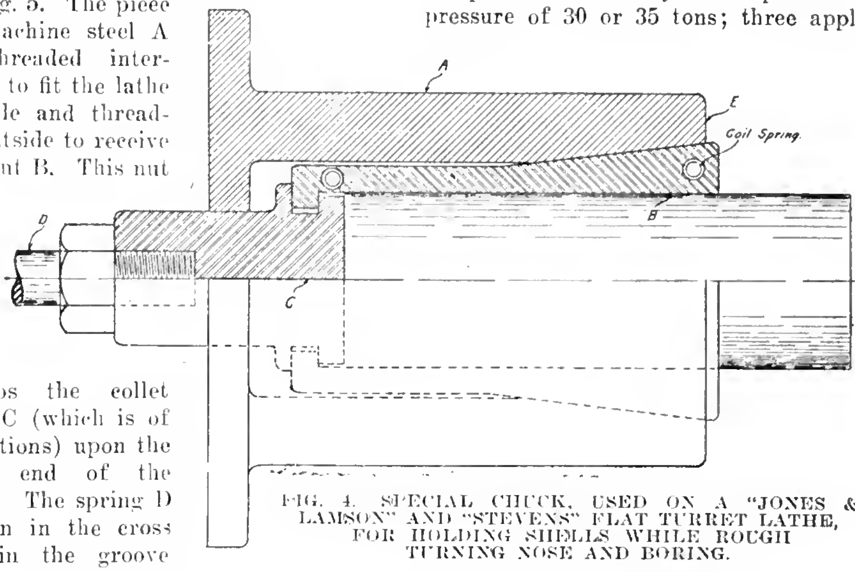

FIG. 4. SPECIAL CHUCK, USED ON A "JONES & LAMSON" AND "STEVENS" FLAT TURRET LATHE, FOR HOLDING SHELLS WHILE ROUGH TURNING NOSE AND BORING.

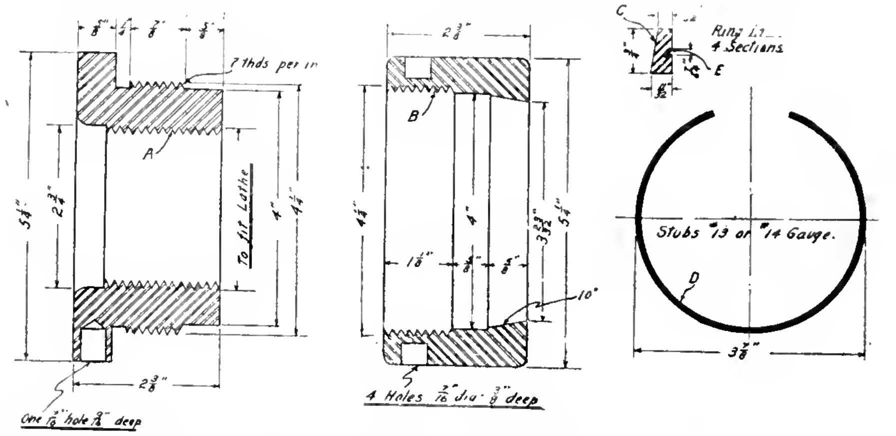

FIG. 5. CHUCK FOR HOLDING BUTT END OF SHELL WHILE BODY OF LATTER IS BEING GROUND.

Putting on Copper Band.

After being ground the copper bands are pressed on in a hydraulic press at a pressure of 30 or 35 tons; three applications are given, the shell being turned a little each time.

Filling the Shells.

After the band turning operation the shells are ready to receive the charge

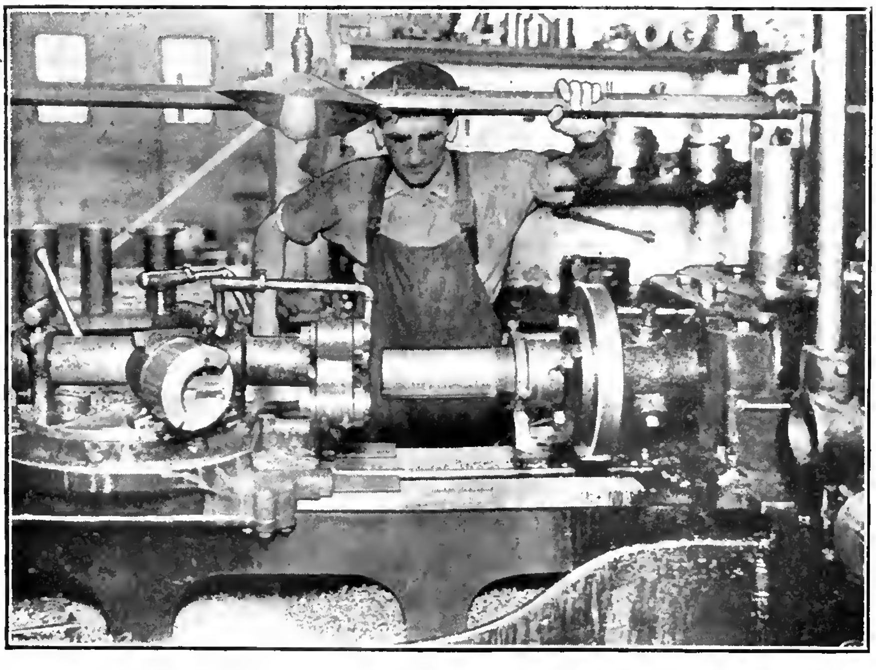

FIG. 2. ROUGH TURNING SHELL BODY ON "STEVENS" FLAT TURRET LATHE.

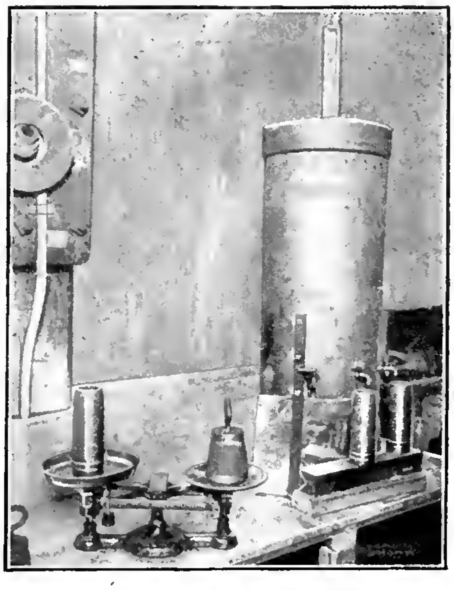

FIG. 6. RESIN MELTING FURNACE SHOWING SHELL FILLING AND WEIGHING ARRANGEMENTS.

of bullets and resin. The tin powder cup is first put in and allowed to fall into position beneath the diaphragm. The shell is placed on end and the brass tube screwed into the diaphragm. After filling the space around the tube with bullets the shell is placed on an air vibrator and the shot jarred and packed in until the weight of shell and bullets equal 16 lbs. 6 oz. 7 dr. The shell is then placed beneath the tap in the resin melting furnace shown in Fig. 6 and sufficient molten resin allowed to run in to bring the weight up to 17 lbs. 2 oz. 10 dr., one of the balls in the

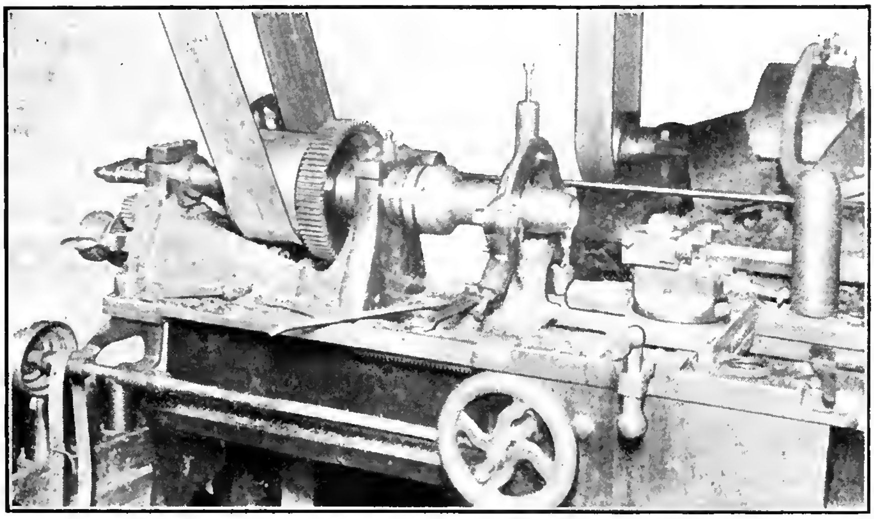

FIG. 7. FINISHING NOSE OF FUSE SOCKET ON LATHE WITH SPECIAL DRIVE.

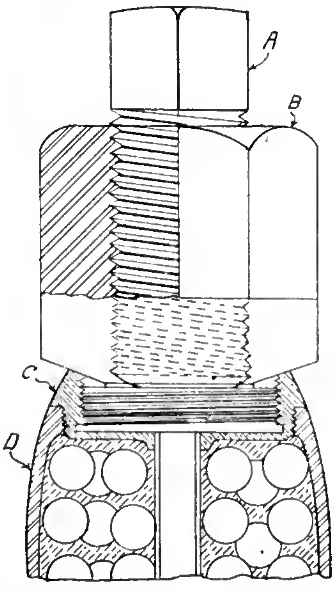

FIG. 8. TOOL FOR REMOVING BRASS SOCKETS.

shell being placed over the opening in the tube to prevent the resin from flowing in.

Finishing the Fuse Socket.

The shells are then held in a chuck and the fuse socket firmly screwed in. They are then held in a chuck similar to that shown in Fig. 5 on a London tool lathe and the rough part of the fuse socket finished to the desired shape and size. A feature of this operation was the replacing of the ordinary cone pulleys by a single wide faced pulley to increase the driving power. This operation is shown in Fig. 7.

Final Weight Test.

The shell is now ready for the final test for weight and inspection before painting. The weight at this point

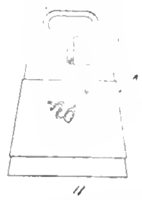

FIG. 11. LIMIT WEIGHT.

should be 17 lbs. 10 oz. 14½ dr. This was done on a Gurney scale. Now, if the shell weighs more than the limit allowed the base is faced off until the desired weight is obtained, but, if on the other hand the shell is too light the fuse socket must be removed and sufficient small shot added to bring it up to the required weight. To remove this fuse socket after it is finished requires some careful handling. The tool shown in Fig. 8 was used for this purpose. A is a threaded plug which screws into the fuse socket C. The shank of piece A is threaded left hand and squared on the end, the nut B is threaded to fit the thread on the shank. The shell is securely held in a chuck and the plug

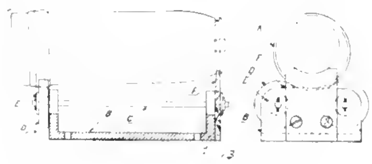

FIG. 13. PAINTING JIG.

screwed in, then the nut is screwed on until it comes in contact with nose of fuse socket, further pressure causes the socket to unscrew when the additional weight is inserted and socket replaced.

Facing Fuse Socket.

The beveled bearing on the nose of the socket is then finished by facing

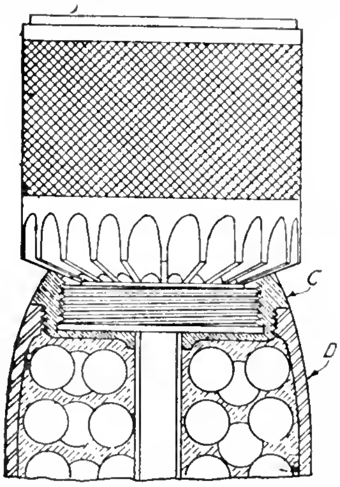

FIG. 9. TOOL FOR BEVELLING BRASS SOCKETS.

with the tool shown in Fig. 9. The threaded plug with shank extended as

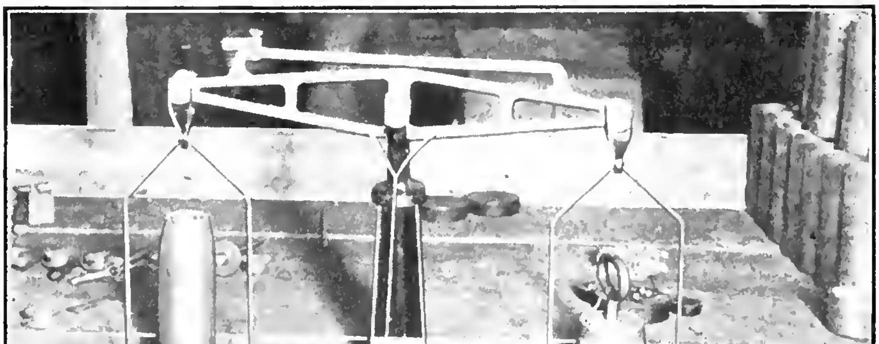

FIG. 10. INSPECTION BENCH SHOWING A FEATURE IN THE USE OF A SINGLE WEIGHT TO TAKE THE PLACE OF SEVERAL STANDARD WEIGHTS.

at A, Fig. 8, is screwed into the socket and the knurled rosebit B placed over the shank and turned by hand making a smooth joint for the time fuse piece.

Weighing Feature.

A feature in connection with the weighing of the shells at various stages was the replacing of several standard weights by one solid weight, as that shown on the scales in Fig. 10. This weight is more clearly shown in Fig. 11. The piece A was cast of a weight about equal to the required weight then drilled and tapped to receive the eye bolt B. The ends of piece A were then turned off until the exact weight was reached and then used in preference to the other weights and the adjustable weight on the upper beam. Instead of using this movable weight on the beam for finding the amount under or over, the piece of string solder, shown at C, was made the exact weight allowed over and above. This piece is shown on the top of weight in Fig. 10.

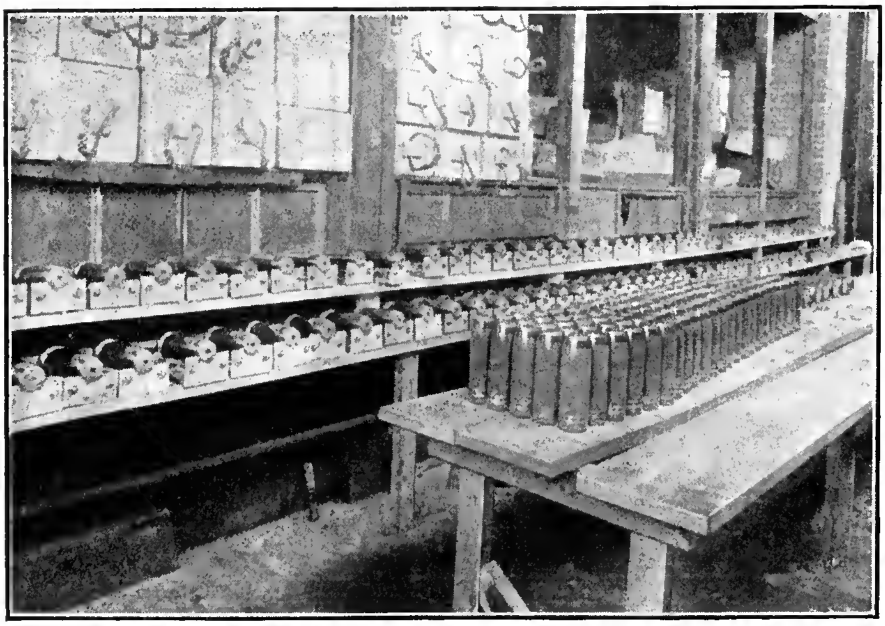

FIG. 12. SHELL PAINTING DEPARTMENT.

Marking and Painting.

After the shells have been finally passed they are marked in a Brown Boggs marking machine. They then go to the painting department a view of which is shown in Fig. 12. The cases in the upper left hand corner are used in shipping the finished shell. The jig used for painting the shell, of which there are a large number, is shown in Fig. 13. The frame is a light casting which carries the two shafts C on which are the rollers D held in position as shown. At the front end is a thin piece of board secured to the frame and hollowed out to receive the nose of the shell; a crank handle is fitted in the square hole and the shell revolved while being painted.

This plant is turning out from two to three series, (240 to 360) shells a day.

CANADIAN LIGNITE INVESTIGATION.

LIGNITE obtained from the Province of Alberta has been under investigation by the Department of Mines, Ottawa, and a report of over 100 pages has been issued covering the results. This report, which is made by B. F. Haanel, chief of the Fuels and Fuel Testing Division of the Department, and John Blizard, states that in an extended number of trials in gas producers the fuel was found eminently suited for such gas production. In fact, it is suggested that the nitrogen content is sufficiently high to make recovery of ammonia or ammonium sulphate profitable. It is added that no trouble was experienced in utilizing the gas in a gas engine.

The tests cover also the use of the lignite under steam boilers, and it was concluded that lignites with a moisture content up to 30 per cent. do not materially affect boiler efficiency. It is explained that fuels of this class require a specially large combustion chamber and a brick ignition arch arranged to burn the large percentage of volatile matter contained.

HARDNESS AND WEARING TESTS OF METALS

AT the suggestion of the Hardness Tests Research Committee of the Institution of Mechanical Engineers, some comparisons of the results of the different methods of testing the hardness and wearing properties of metals have been made. using specimens supplied by Sir Robert Hadfield. The comparisons made up to the present time have been between the results of the "Brinell" ball hardness test and the "Saniter" wear test.

For the purpose of making the latter test, the existing Wöhler fatigue testing machine was used with a 1-in. specimen rotating at 2,200 r.p.m. A hardened steel ring of 1½-in. internal diameter and 0.25 in. wide, was placed on the specimen and loaded with a weight of 210 lb. The wear was taken as the reduction in diameter of the specimen in ten-thousandths of an inch after 200,000 revolutions of the specimen. The results showed that the relation between the "Brinell" hardness number and the resistance to wear (as given by the reciprocal of the wear in ten-thousandths of an inch multiplied by 1.000), depends largely on the composition of the steel. In ordinary carbon steels a high resistance to wear (18 to 20) corresponded with a high hardness number (720), whereas, in manganese steels having a relatively low hardness number (241 to 286), the resistance to wear was extremely high (27 to 30).

In the wear test it was found that the effect of the vibrations of the wearing ring on the wear was very marked, so that it was difficult to repeat the tests. At the suggestion of the Committee, designs for a wear testing machine are being prepared, in which it is hoped that this difficulty will be overcome.—National Physical Laboratory Sectional Report.

QUEER HABITS

PEOPLE engaged on repetition work sometimes form queer habits, which appear to have no useful connection with their work. In a certain shop the heads of hexagon bolts were chamfered in a simple lathe, the bolts being screwed into a cylindrical block or chuck mounted on the spindle. As soon as the screw was tight the workman hit the chuck a resounding whack with a spanner. Both chuck and spanner showed that this must have been done millions of times during the years that the man had been on the machine. No useful purpose was served, but the habit had become automatic and could not be discontinued. The man could give no explanation as to why he did it and the origin of this curious habit remains wrapped in mystery.

A similar case is that of a workman who had to wheel broken stone in a barrow and tip it into a deep excavation for the foundation of a building. After tipping his barrow he would let go the handles and raise his hands above his head with an expression of horror on his face, apparently at the awful fate of the stones.

Radiator and Boiler Manufacture in a Modern Foundry

Staff Article

The production of steam and hot water heating apparatus is a highly specialized development in modern iron founding. Systematic care and increasing attention are necessary for the continued production of satisfactory work.—In the following article a brief description is given of a visit to one of those plants which have earned for Canadian manufacturers in this line, an enviable reputation for quality of product, due to good workmanship and material.

THE No. 3 plant of Steel & Radiation, Ltd., is situated on the outskirts of the town of St. Catharines, Ont., a progressive and flourishing community of over 14,000 inhabitants. The Grand Trunk Railway System supplies convenient transportation facilities and the comparatively close proximity of such manufacturing centres as Toronto, Hamilton, Welland, Niagara Falls, and Buffalo, ensures a favorable market in which to secure labor, materials, etc. The plant, which is comparatively new specializes in apparatus for steam and hot water heating and full advantage has been taken of such methods and equipment as can be adopted where high class repetition work is required.

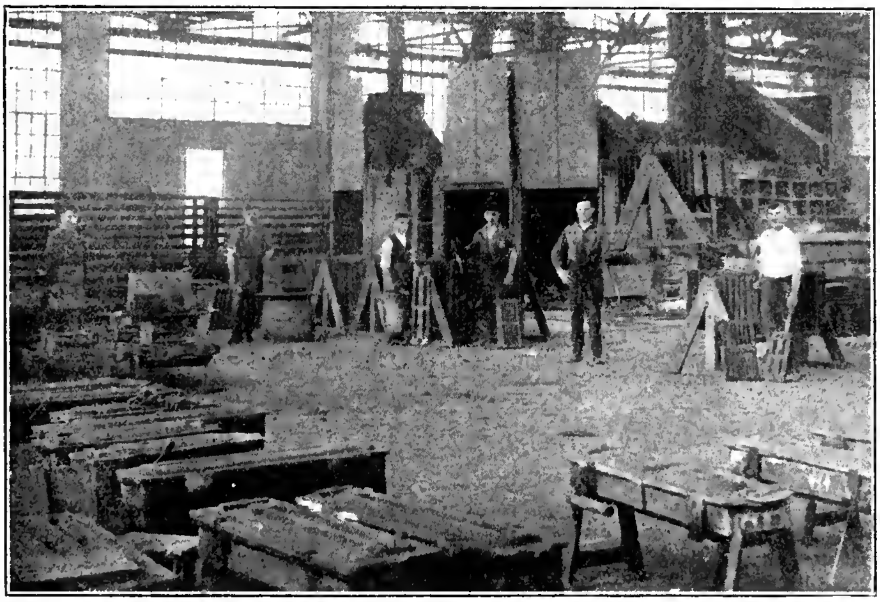

FIG. 1. FINISHED CORE AND CORE OVEN DEPARTMENT.

Buildings

The buildings consist of three principal bays running north and south and connected by a spacious cross aisle. The pattern shop, pattern store, and stock room are separately housed in detached buildings to the north of the main structure. All of the buildings are of modern design, an important constructional feature being the liberal use made of "Fenestra" steel sash, which is manufactured in Canada by this company. The efficiency of this product in providing light and ventilation is widely recognized, and its use, combined with ample height and floor space, provides ideal conditions for foundry operations. With the exception of the moulding department which is paved with brick, the shop has wooden floors throughout and in all respects is thoroughly representative of this particular sphere of modern foundry practice.

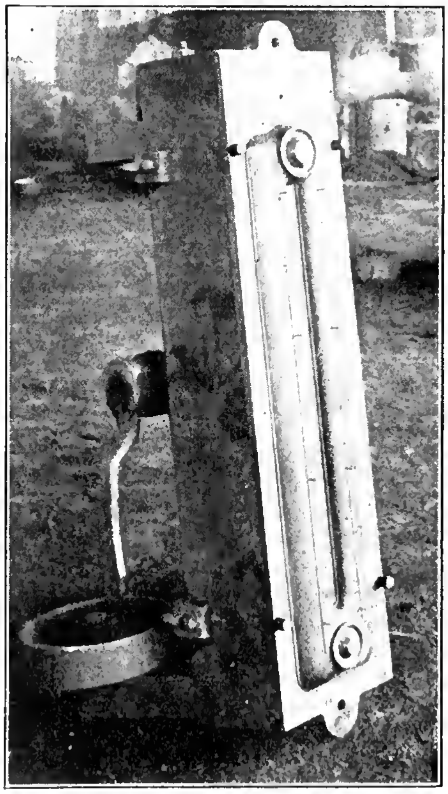

FIG. 2. MOLDING MACHINE FOR RADIATOR SECTIONS.

Raw material consisting of pig iron, coke, sand, scrap iron, etc., is delivered on the railway siding close to the cupola, a suitable covered storage space enabling a stock of material to be kept on hand

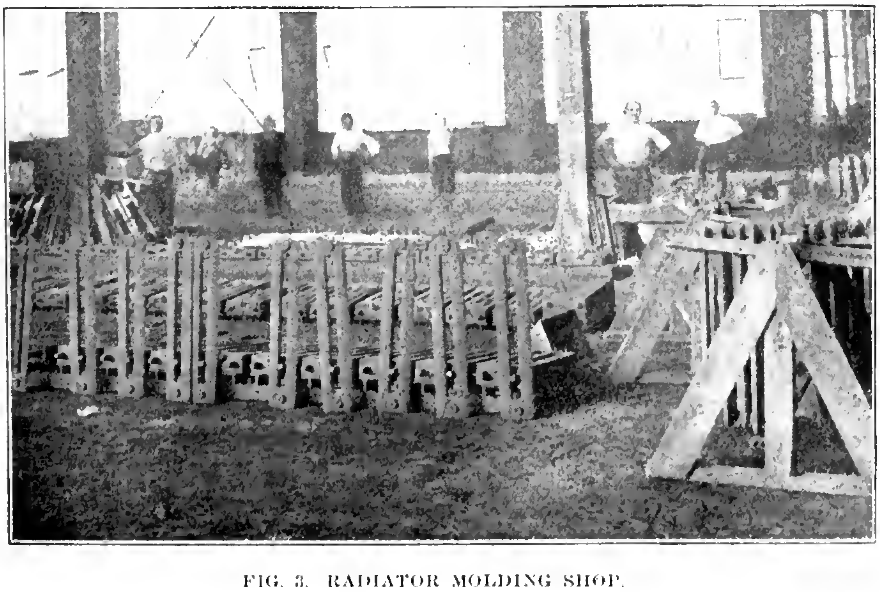

FIG. 3. RADIATOR MOLDING SHOP.

should weather conditions interfere with its handling in the open.

Cupola Installation

The cupola is installed at the east end of the cross aisle and ample space is provided to allow of safe and rapid handling of the ladles. Close to the cupola is the blower room in which is a large "Connersville" blower of ample capacity, belt driven by a 50-horse power motor. Two belt driven air compressors supply compressed air for hoists, etc. The cupola elevator gear is conveniently situated in this room and is operated by a 15-horse power motor. Electrical energy is obtained from Niagara Falls, the shop equipment including a transformer set which supplies 3-phrase 25-cycle current at a pressure of 550 volts.

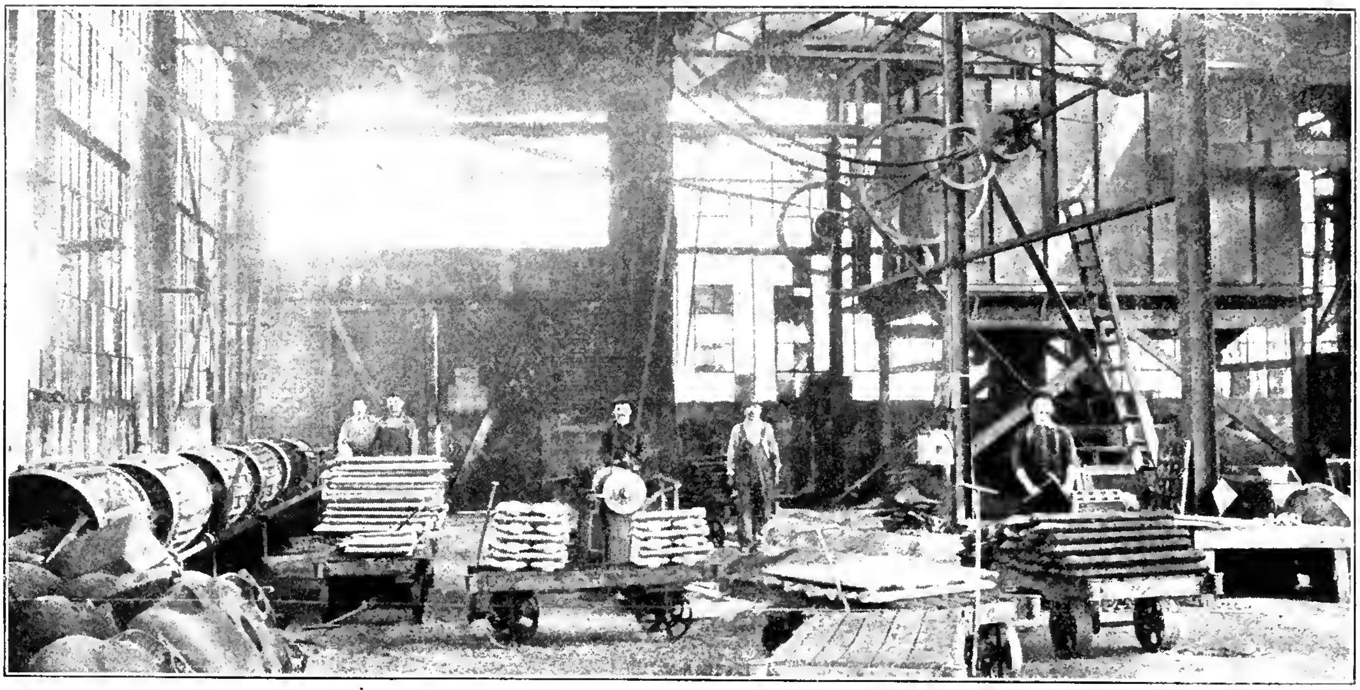

FIG. 5. GENERAL VIEW OF FETTLING SHOP.

Owing to the high grade of work required, metal patterns are used almost exclusively. After the cores are formed of specially prepared sand, they are placed on trucks with suitable bodies and run into the drying ovens. A transfer truck runs on a track across ea... e of the core ovens thus allowing any rack to be put into any oven, and when dried, to be placed in any desired position, in the storage space, where the cores are arranged on frames for transference to the moulding department.

Modern Methods

As would be expected in a plant of this description, moulding machines are largely used, Fig. 2 showing one type of machine which is simple, strong, accurate, and quick. Fig. 3 shows a view in the

FIG. 4. HEATING BOILER MOLDING SHOP.

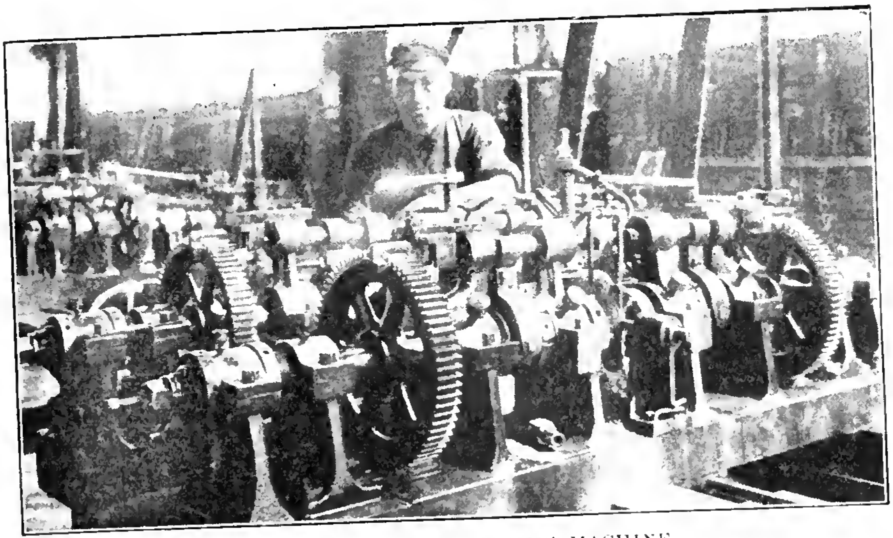

FIG. 6. TAPPING AND FACING MACHINE.

under hydraulic pressure. Specially designed fixtures enable this operation to be accomplished rapidly and satisfactorily.

Although the actual amount of machine work on radiators is not great, it has to be performed with a considerable degree of accuracy. The faces of the bosses which join each other must all be parallel; there must be exactly the same thickness from face to face, and the two faces on either side must be exactly in line. While slight inaccuracies do not appreciably affect a radiator composed of say six or less sections, the cumulative affect of bad machine work on 18 or 20 sections is quite apparent to a casual observer. Special machines which tap and face the four holes of a section simultaneously with the required

moulding shop, it being amply equipped with traveling air hoists, which save considerable time and labor in conveying the ladles of hot metal to the moulds. An overhead electric hoist travels on a track along the cross aisle and is used for transferring work from one bay to another.

A view of boiler moulds in course of preparation is shown in Fig. 4. The number of different pieces required in producing the boilers is greater than with radiators, in addition, the shape of the parts does not allow of the same moulding methods being pursued. As a result of this, the methods in use are similar to those generally adopted in the production of high grade foundry work, skilled labor and the best of materials and equipment being indispensable to the maintenance of the company's standard of excellence. A complete equipment of sand blasting and rumbling machinery is installed, and after being thoroughly cleaned the various parts are tested

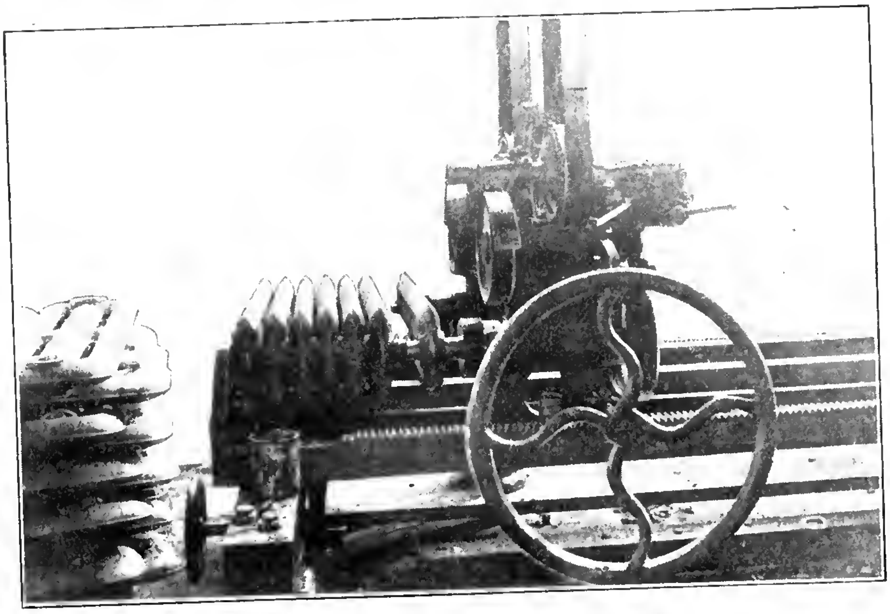

FIG. 7. RADIATOR ASSEMBLING MACHINE.

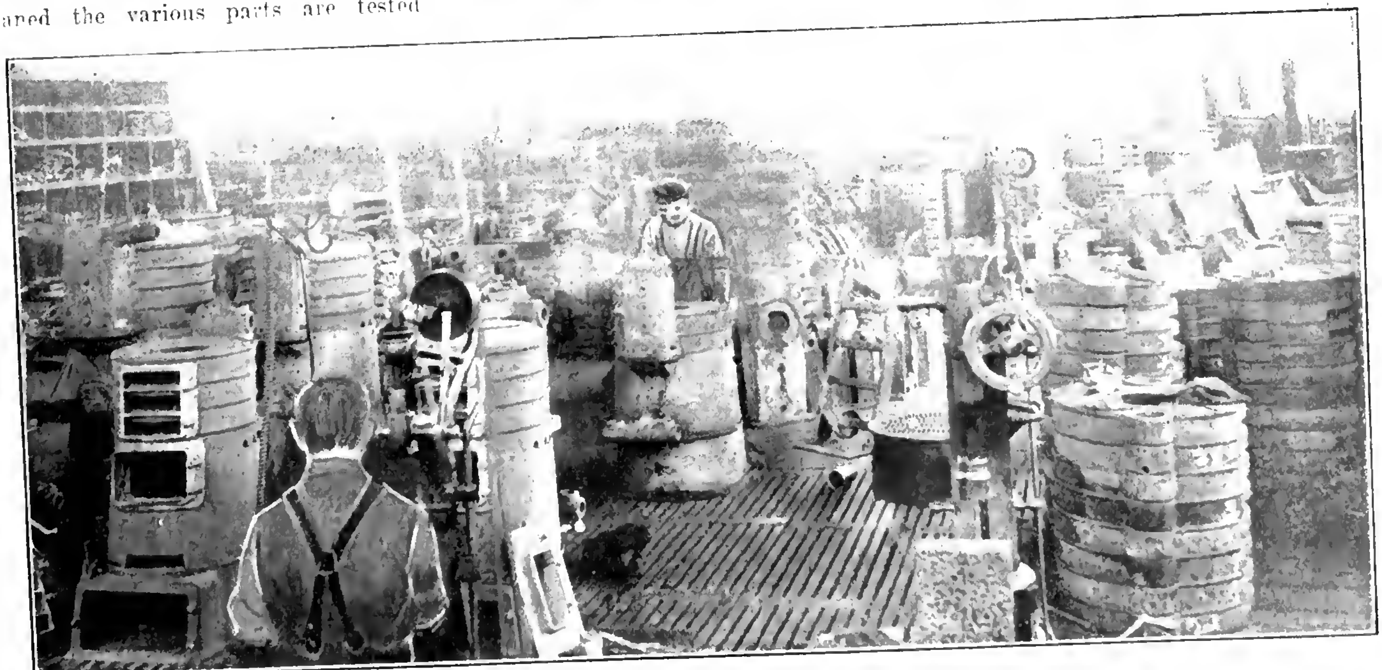

FIG. 8. HEATING BOILER ASSEMBLY DEPARTMENT.

degree of accuracy have been designed and built in the plant.

As can be observed in photograph, Fig. 5, the machine consists of two carriages, each of which carries two spindles. One of the carriages is rigid while the other is adjustable along the ways in the foreground of the picture. The machine shown has an adjustment of from 20 inches to 45 inches between centres of spindles, sufficient to handle all ordinary radiator sections.

Radiator Assembly

The threaded nipple system of construction is used exclusively in the company's radiators, making it thereby possible to produce tighter joints with less possibility of damage to the castings than when the push nipple joint is used. The latter method involves the use of tie rods or braces, which are unsightly when used externally, and interfere with the circulation when used internally. Furthermore, it is an easy matter to dissemble a threaded nipple for repairs, whereas a push nipple joint can only be separated at considerable risk of damage to sound parts of the radiator. As a result of this method of construction, few, if any, sections fail when the final hydraulic test is applied to the assembled unit.

Conditions render the use of push nipples desirable in the construction of steam and hot water boiler of which this firm has a large output. Push nipples of the spherical type as used by the company allow the component parts of a boiler to adjust themselves in use so that undue strains are avoided and all possibility of leakage is entirely prevented.

A well equipped machine shop and tool room are, as might be expected, a necessary adjunct of such a plant, and contribute to that quality of product for which the company have earned quite an enviable reputation.

LAKE SUPERIOR CORPORATION

SURPLUS profits from operation of the subsidiary companies of the Lake Superior Corporation in the year ended June 30 last amounted to $1,366,210, a decrease of $1,145,125, or about 45 per cent. The return does not include any figures from the Algoma Central & Hudson Bay Railway, which went into a receivership during the year, and to that extent the comparison cannot be exact.

The return giving the output of the main company in the group, the Algoma Steel Corporation, reveals, however, the source of the great shrinkage in earnings. "The production of pig iron, rails and merchants' mill material," says the directors' report, "is less than for the previous year on account of the sharp falling off in demand which was experienced towards the end of the year." The output, in tons, compared with the preceding year, was as follows:

	1913-14	1914-15
Pig iron	311,904	212,917
Steel rails	325,680	174,536
Merchant mill material	15,575	8,903

The subsidiary companies, after paying interest on bonds amounting to $1,166,414, writing off $62,000, providing $134,423 for sinking funds, appropriating $54,209 for reserves and paying to the holding company $342,859 as interest on bonds, etc., showed a deficiency of $393,695 for the year. This wiped out the $61,930 carried as unappropriated profits and left a net deficiency of $331,765 at the end of the year.

The total income of the holding company, Lake Superior Corporation, was $369,032, against $448,054 the previous year. After paying interest and expenses the balance remaining as net income for the year was only $1,661.

MELTING FURNACE DATA

IN the course of a paper read before the British Foundrymen's Association, F. C. Barker referred to the various forms of tilting type coke-fired furnace, both those heated on the regenerative system and ordinary firing. He specified one of the former in which the furnace body consists of two light steel shells, one within the other, the grate-bars being carried within the inner body and a preheater being fitted above. The working results for this furnace are given for the 400 lb. size as follows:—Time of melting 8½ hours; average metal to coke 5 lb. or 6 lb. to 1 lb.; life of crucible 60 heats.

For another furnace of the same general construction, but without pre-heating for the air, the following results were attained from practical foundry working over a period of 12 months:—450 lb. size furnace, average life of crucible 50 heats, coke consumption 4 to 1; 250 lb. size furnace, average life of crucible 60 heats, coke consumption 6 to 1.

Compared with coke-fired pit furnaces, these tilting furnaces show a saving of 50 per cent. in crucibles, and 50 per cent. in coke, while the amount of ash, owing to the better combustion of the fuel, is less by 80 per cent. The first-mentioned of these furnaces can be adapted to burn crude oil.

Oil fuel has several distinct advantages. The furnace can be started up directly the oil and air jets are opened up. One man can look after several furnaces. There is no cleaning out of the furnace at the end of the day, and little storage room is required. The furnaces require no stoking or poking, and the melting can be conducted in a reducing atmosphere. A long life is assured to the crucibles, and a wide range of temperatures can be obtained.

GOLD OUTPUT INCREASES

THE Department of Mines reports that the total gold output in Ontario for the six months ending June 30, 1915, amounted to $3,570,072. Last year the value of the output was $2,011,069. Of the total yield for the half year, $3,267,620 was mined in Porcupine. This shows that the output from the Porcupine mines is growing, and if maintained will show a 50 per cent. increase over the yield for 1914.

The department reports progress in many of the mining districts, and says that the prospects for a large output of gold ore from these mines are very bright. Some of the mines mentioned are: The Huronia at Kirkland Lake, Goodfish Lake camps, Munro camps, Howard's Falls (Kow Kash).

The output of silver continues to diminish. There is a difference of $1,864,655 between the output of 1914 and the decreased output for the half year of 1915. Nickel has been mined more extensively. Compared with the previous year, the value of the nickel mined has increased 18 per cent., and that of copper 2 per cent.

The figures for the six months in 1915 and 1914 are, respectively: Gold—$3,570,072, $2,011,069; silver—$5,188,763, $7,053,418; copper—$1,229,894, $1,197,059; nickel—$3,393,528, $2,872,843; iron ore—$288,296, $118,119; pig iron—$2,856,040, $4,429,664; cobalt—$34,443, $22,581; cobalt oxide (including nickel oxide)—$56,812, $379,152.

Experience.—A graduate should emerge from the engineering school possessed with intellectual humility rather than intellectual arrogance, and should realize that without experience his engineering judgment will be of little value. —Professor Swain.

Studies.—No man ever gained much from studies pursued for the selfish purpose of broadening himself out, without some definite relation to his usefulness as a citizen. We have an example of futility in the literary education pursued in China for 2,000 years, with no possible relation to the students' subsequent careers. If a student's inner motive is not greater power for the service of others, his education is a flat failure and his satisfactions are barren of happiness.—Professor Adams.

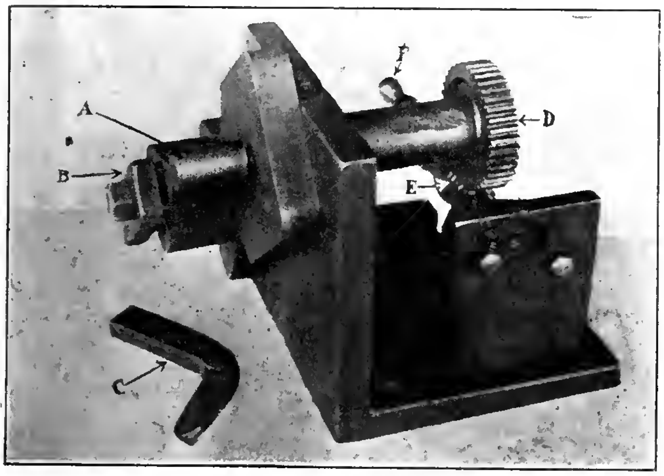
PRODUCTION METHODS AND DEVICES

A Department for the Interchange and Distribution of Shop and Office Data and Ideas Evolved from Actual Practical Application and Experience

SHAPING CIRCULAR PIECES

By G. E. Luck

A USEFUL device for machining circular pieces on a shaper is here shown. The piece shown at A is a rocker for a small punch press, though any similar piece may be machined in the same way. This rocker has a hole bored in its widest part for the crank pin, and this bored hole is used to locate by, as it is set over



SHAPING CIRCULAR PIECES.

a large pin inserted in the holding plate. The clamp B holds the work securely in place. A pointed pin in the holder-plate marks the centre of rotation and a punch mark in the piece to be machined is set over this pin in order to line up properly for the cut. The cutting is done with an extension tool like that shown at C. The holder-plate is attached to a spindle which has the gear D on its opposite end. A worm E meshes with the teeth of this gear, so that as the ball crank F is slowly turned, the work is revolved under the cutter. Once set, work may be machined about as rapidly in this way as ordinary flat work.

SUGGESTION FOR CUTTING SPIRALS

By S. Leeman.

I WAS very much interested in reading Mr. Miller's suggestions in your issue of Sept. 9 for cutting spirals.

Suppose we were cutting spiral grooves 6-in. lead and ¼-in. deep in a 1-in. piece, then according to his method of laying out or unrolling the piece, we would have a rectangle 6 in.×3.1416 with a groove diagonally across from corner to corner. Now, 3.1416 ÷ 6 = .5236, which is the sine of the angle between the diagonal groove and the side of the rectangle. Looking this up in a table of sines we get 31° 35′.

Let us now unroll the circle made by the bottom of the grooves where it is only half the diameter, and we get a rectangle with a height of 6 in. and a base-line of 3.1416 ÷ 2 = 1.5708. Again, 1.5708 ÷ 6 = .2618, and the angle corresponding to this is 15° 11′.

Now, if Mr. Miller has a cutter cutting an angle of 15° 11′ at one part of the groove and 31° 35′ at another, to which angle does he set his miller?

Another point in the article which is not very clear to me is where he says the difference in the length of the base-line and the upright line is the ratio between the turning gears and the feeding gears.

If Mr. Miller means that the ratio between the length of the two lines is the same as that between the revolutions of the two gears, he is hardly correct, for as I have shown, we may get different rectangles, giving different ratios, from different diameters and yet having the same lead produced by the same gearing.

If we call the base-line in all cases one, to represent one revolution of the work, and multiply it by 40 to get the revolutions of the gear necessary to revolve the work once, and we multiply the height of the rectangle, 6 in., by the pitch of the table screw, usually 4, to get the revolutions of the screw necessary to traverse the work that distance, we get 40 and 24 as the gears to use, or 5 to 3 as the ratio of the gearing; but as the table screw must turn fewer times than the worm, we must put the larger of the gears on the screw and the smaller on the index head.

INCREASED PRODUCTION ON MARKING MACHINE

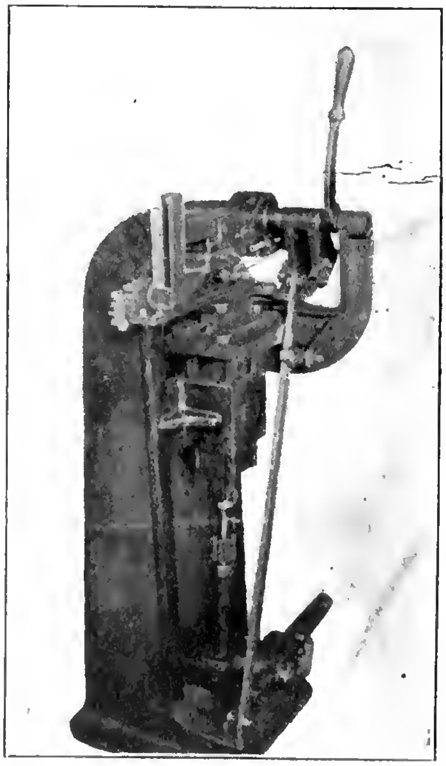
By D. A. Hampson

A MACHINE that was little known in most quarters before the recent manufacture of munitions was begun is the Dwight Slate marking machine. It is made in two styles—one for marking cylindrical work, and one for marking flat work. We had used one for years and not many months after the war's inception found it over-taxed and considered purchasing another.

The work that was wanted most was the marking of vast quantities of a steel piece that for all practical purposes may be considered as ⅛ in. x ¾ in x 1¼ in. These came to the machine more or less oily which, added to their thin shape, made handling difficult and production aggravatingly slow. Some study of the problem convinced the writer that improvements could be made—accordingly the work was done, and it fulfilled all expectations.

The Improvements

The photograph shows the machine as "improved." An extension on the table carries a vertical feeding chute that holds sixty pieces. To the horizontal slide (which carries the roll stamp) will be seen fastened a casting extending past the chute; it has, at its lower side, a dog which pushes out the bottom piece of the pile. The handle has also been changed from the back to the front of the machine, the pinion shaft lengthened, and provided with an outboard support. Further, the shaft drives a casting having an



IMPROVED MARKING MACHINE

internal runway for the two rollers that will be noted at the upper end of the diagonal bar. This bar raises the work table instead of having it done by the foot of the operator. The rollers drop

off the runways at the end of the stroke and the table returns by gravity. One end of the runways is hinged—as may be seen—this permits the return and the drop into position, ready to pick up the rollers for a new stroke. So arranged, a complete stroke of the handle feeds a new piece to the stamp, raises the table, marks the piece, and returns all parts to the starting point.

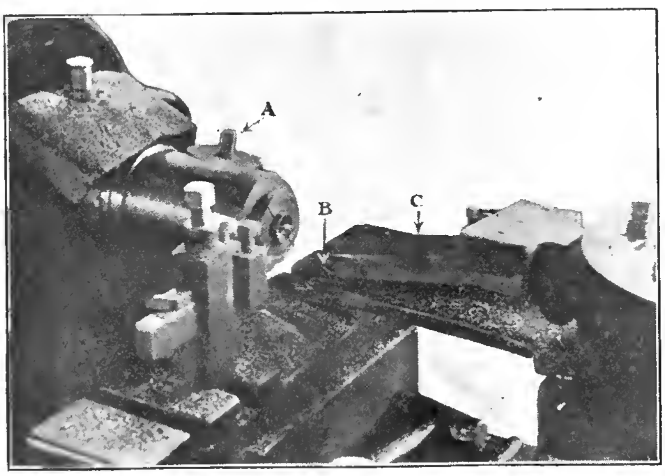
Reduced Labor

After loading the chute, the operator has but one thing to do—move the handle—as the pieces are confined in a trough that leads out at the back into work boxes. Relieving the operator of the mental and physical exertions of a hand movement, or foot movement for unloading, and for most of the loading increased the production two hundred per cent. A less skilled operator now does the same work and congestion no longer exists at the marking machine.

A TURRET CROSS-SLIDE FEED

By A. E. Granville

IN machining the piece shown at A, it is chucked by the stem and faced off. Being considered easier for the operator, and less liable to throw chips in his eyes, a cross-slide feed was made to be operated by means of the turret capstan. This was done by placing a hardened roller on the cross-slide at B, and a diagonal slide C on the turret. From this it will be seen that as the turret is fed toward the chuck, the cross-slide will be forced to move toward the back and carry the cutting tool across the face of the work. As the turret is run back a spring pushes the cross-slide toward the front and clear of the work.

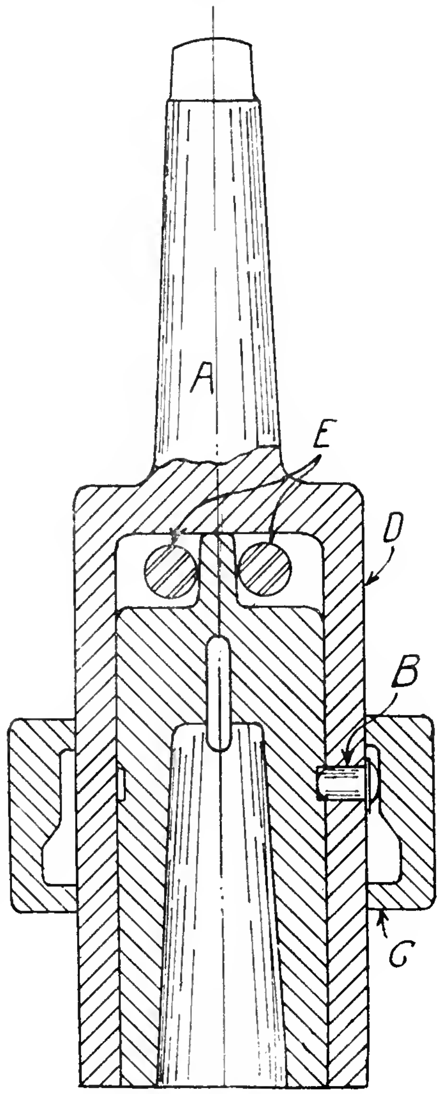


TURRET CROSS SLIDE FEED.

A SIMPLE DRILL CHUCK

THE removal of drills from their sockets by means of a drift is at best a poor method. This is especially true when used on multiple-spindle drills. On these machines, since there are several drills in simultaneous action, the waste of time required in removing one by the old method is indeed quite costly.

There are several drill chucks on the market which allow the drill to be removed while the machine is in motion, and that here described and illustrated is among the simplest we have seen. The chuck body A has a tapered shank which fits the machine spindle. Through the chuck body is fitted the pin B, and this pin is operated by the sliding collar C. After the pin has been fitted in place, the collar C is slipped over ,this being accomplished by means of a slot in bottom face of the collar. Through the top of the body are fitted two circular pins E. These engage with the tang of the adapter, thus driving it. The adapter D is pushed up into the body of the chuck when the collar is in its top position and is held in place by means of the pin B engaging with the annular groove machined on D.



A SIMPLE DRILL CHUCK.

From the foregoing the operation of the chuck can be easily followed. To remove the adapter from the chuck body it is only necessary to hold it lightly in one hand while the other pushes up the sliding collar. This allows the large diameter of the bore to come opposite the head of the pin B. A slight downward pressure on the adapter causes the pin to slide out from the groove, thus leaving the adapter free to be removed. With this appliance it is advisable to carry a full line of adapters bored out for the complete range of drills. Where this chuck has been used it has been found to give complete satisfaction.

SHRAPNEL SHELL SOCKET TOOL

By Geo. Armstrong

NO doubt several manufacturers in the shell industry have found more or less difficulty in securing a suitable apparatus for screwing the fuse sockets into place, or in removing a finished socket from the shell without marring the same. The latter is often necessary and must be done in order to rectify faulty weights. When the shells are finally inspected, they are often found to be under weight and in order to bring them to the desired standard it is necessary to remove the brass socket and place shot in the shell, till the correct weight is reached.

The tool described in this article is one that has been found to give entire satisfaction for this particular feature of the work. Referring to Fig. 1, the stud is turned from the solid and is made in two diameters, the larger diameter being threaded 14 threads per inch, R.H., to fit the thread in the fuse socket. The thread pitch of the smaller diameter is the same but the thread is left hand. A square head is milled on the top of the thread, and is made to fit a standard size wrench. The L.H. nut is made as shown in the sketch, the large diameter being bored to a bevel similar to that of the outside diameter of the fuse socket.

When it is required to screw a semi-finished socket into place, the nut C, Fig. 2, is first run back a sufficient distance in order to allow the larger thread to be screwed into the fuse socket, and within two threads of the bottom. The nut C is then turned back till it binds against the top of the socket. A wrench is placed on the head D of the stud and is turned to the left, or in the direction required to screw the R.H. thread. The action of the right and left hand thread is to bind the nut C, and the fuse socket tightly together. The fuse socket, nut

and stud then screw down as one unit till the shoulder of the fuse socket binds against the shell. To remove the tool, all that is necessary is to put a wrench

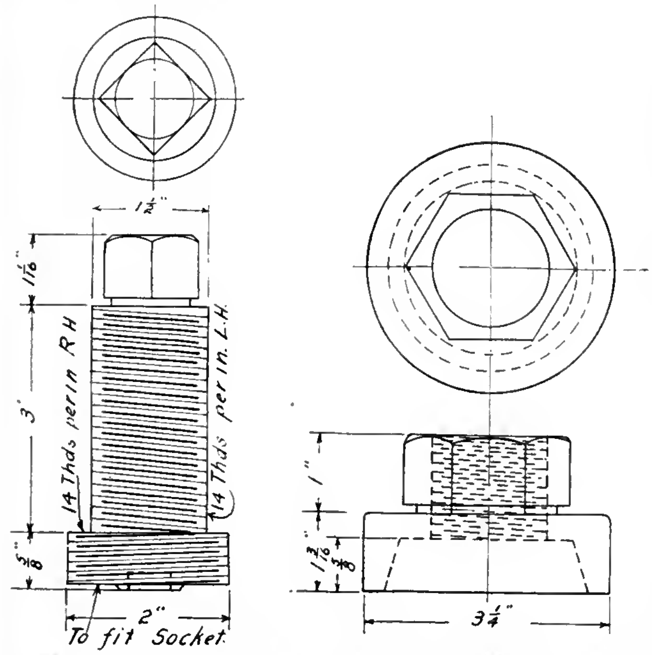


FIG. 1. STUD AND NUT FOR SHELL SOCKET TOOL.

on the nut C, and loosen it by turning to the left, at the same time holding the stud stationary with the other wrench. The plug, thus released, can be easily screwed out of the socket.

The removal of a finished socket from the shell is done in the manner illustrated in Fig. 2. The plug A is screwed into the socket to within one thread of the bottom and the nut C is brought

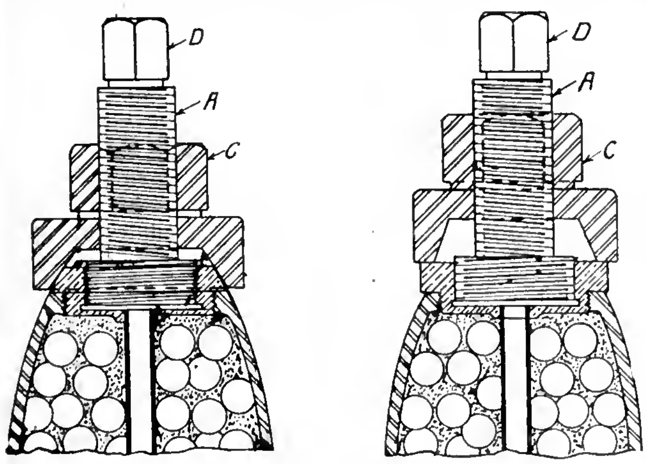

FIG. 2. APPLICATIONS OF SHELL SOCKET TOOL.

down against the socket, a wrench being then placed on the nut C, and turned to the right. The action is similar to the previous arrangement, the right and left hand threads again having the tendency to bind both the nut and socket together, thus allowing the latter to be withdrawn. The tool is removed by the socket in a similar manner as already stated, that is, a wrench is placed on the head P, and is held stationary while the nut C is loosened by the other wrench.

BELLOWS and Tilt Hammers.—An inquiry into the evolution of the bellows would yield some valuable information on the steps through which metal working progressed in the past centuries. In the small, but little known, museum at the Record Office in Chancery Lane, there are two sixteenth-century drawing attributed to Lord Burghley. They illustrate a phase of lead-smelting in Derbyshire. One, described in one corner as the "Old Order," shows two men each standing on a pair of bellows, the nozzles of which are directed towards a furnace. The other picture, inscribed "Burchardes Furnise," is quite elaborate. There is a rough representation of a water-wheel outside the wall, with gear connecting to an overhead shaft of wood in the smelting-house. Four bellows are shown attached by as many connecting rods.

Mr. Charles Dawson, of Lewes, has a photograph of a clock-face made at Ashburnham, which was the centre of one of the Sussex ironmaking areas. The dial shows in a quaint fashion some of the phases of the industry: digging the ore, cutting down the trees, charcoal-burning, the interior of the forge, the foundry, and even the checkweighing of the cannon and other output of the works. The picture is the only contemporary representation of a Sussex ironworks of which I have any knowledge.

With regard to tilt hammers, Mr. Lewis, another Sussex antiquarian, suggested that the original tilt hammer was merely pivoted a little out of the centre. There was a free end opposite the tup, on which one or two men stepped to raise it. When they stepped off, the blow fell on the metal on the anvil. Afterwards the blow depended upon a cam, or the sprocket of a star wheel on the waterwheel shaft. Sometimes the pressure was exerted on the top of the free end of the hammer beam, at others under the beam between the pivot and the tup. By these primitive means a good merchantable bar of useful length was hammered out of the bloom. It is on record that as early as 1300 the farrones, or ironmongers, of London were agitating against the Sussex ironmasters, who were delivering iron bars so short that making tyres for cart wheels was rendered difficult.—Practical Engineer.

A NOTABLE Event in Foundrydom.—What might be termed the "modernization of the foundry" has been effected almost entirely within the past twenty years, as it is during this period that the greatest advances have been made, not only in the purely mechanical end of the business, the production of castings and methods of melting and mixing of the metals, but in easing the lot of the worker and making the foundry a more desirable place in which human beings shall live their working hours. In place of the dark, damp, unventilated and unheated frame buildings of the past, we now have fine structures of steel, brick and concrete, lighted by large arc and incandescent lamps at night. The various improvements that have been made are too extensive to be enumerated, even were it necessary; they have extended to all branches of the foundry industry, as every foundryman is well aware whose active career has covered the period in question.

These changed conditions are primarily due to the great educational movement that had its inception in the formation of the American Foundrymen's Association twenty years ago; the most notable event in the history of founding, an event that could hardly fail to result in good to the entire trade, for had little else been accomplished other than to bring foundrymen together to become acquainted with each other and with the men who furnish the supplies and build the machines, the formation of such an organization would have been well worth while, for once foundrymen got to know each other, distrust vanished, and it did not take long to discover that none had a monopoly of foundry knowledge, and that mutual advantage resulted from discussing with each other the various problems and difficulties encountered and the manner in which they were solved or surmounted.—Brass World Editorial.

Correction.—In our issue of August 26th, describing the Lea Simplex Cold Saw the statement was made that "the stock . . . is moved far enough ahead to cut possibly within one-sixteenth of an inch of the finished length." This is quite in error. The makers of the machine guarantee that by means of this gauge plate, "stock is cut to the exact finished length, and absolutely square."

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

NEW PLAIN-TURNING LATHE

UNDER usual circumstances, the plain-turning lathe as such, because of its elementary simplicity would probably not be looked upon as a highly economical manufacturing machine for a shrapnel or projectile shop; but an analysis of its feeds and speeds in their improved forms, and of the manner in which the machine does its work, will show to what extent improvements in its design have made it a manufacturing tool of high rank.

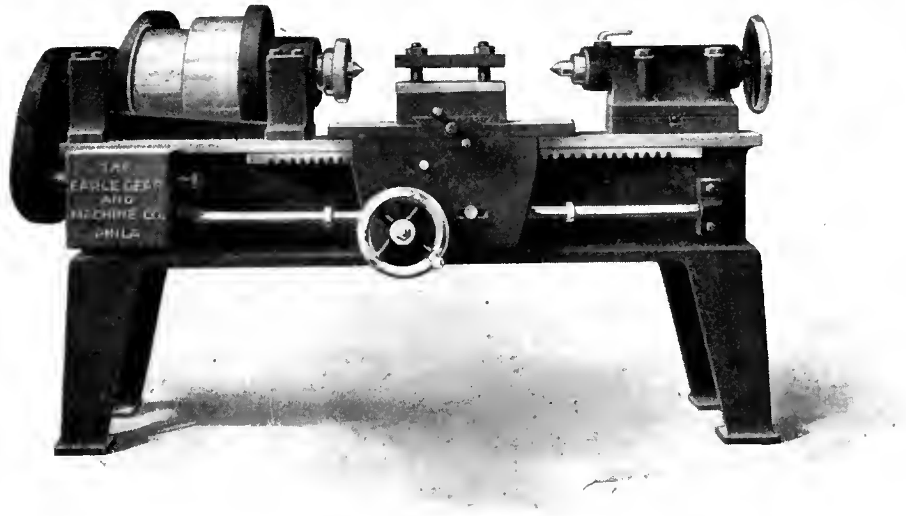
The accompanying illustration gives a good idea of the general character of one of these lathes, as made by the Earl Gear & Machine Co., Philadelphia, builders of the "Lea-Simplex" cold saws. The machine shown here happens to be one with a two-step cone and back gears in the headstock, the swing being 18 in. over a 7 ft. bed. Where preferred it may be had with a variable speed motor, direct connected to the spindle through gears. Other sizes of 20 in x 8 ft. and 24 in. x 8 ft., are also built, and being much heavier and more substantial, are obviously fitted for heavy work such as 4½ in., 6 in., and larger shells.

Everything is arranged for the rapid and easy execution of the various operations. Questions of spindle alignment are avoided in the method of construction. The popular compound rest for the tool post becomes unnecessary, for the simplest form of cross-slide on the saddle will do everything the machine is intended to do.

The turning of the shell nose requires the addition of a forming attachment milled to the contour of the nose. For this operation the headstock spindle is recessed deeply enough (at a diameter larger than the maximum shell the lathe is intended to take) to allow about four and four and one-half inches of the shell to enter. This leaves about four inches for the chuck grip, and gives the lathe tool unrestricted access to the nose. These lathes also take the French 75 m.m. shell.

As the illustration shows the machine is quite simple in design—and its sturdiness is evidenced in the different parts visible in the picture.

The bed which is seven feet long, is cast in one piece with the headstock. This carries with it several decided advantages. In the first place, it establishes permanently the parallelism between headstock spindle and bed; furthermore, it assures alignment of the carriage and tailstock with the headstock spindle. The unusual width of the bearing surfaces of the bed make more than a single "V" unnecessary, the purpose of this being to take up reactions occasioned by the lathe tool.



NEW PLAIN TURNING LATHE.

The greatest distance between centres is 28 inches. The swing over the bed is 18 in. and 10 in. over the carriage. The height from floor to horizontal centre is 40 inches. Much attention has been given the design of the bearings. The front and rear spindles measure 5 in x 6¾ in. and 4½ in. x 5½ in. diameter and length respectively, and are of the ring oiling type. Governed by these dimensions, the diameter of the tailstock spindle was made 3½ in. and given 6 in. travel.

The carriage, which is power driven has long and wide bearings on the bed. This makes movement by hand very easy, and of course utilizes but little power when moving under power feed. Feed changes are handled through slip gears, plunger controlled, which are in a gear box attached to the head end of the bed. A considerable variety for different metals is achieved by the combination of gear box feeds and spindle speeds. In the belt-driven machine, with two-step headstock cone, the combination with the two-speed countershaft gives eight spindle speeds, or 24 combinations of feeds and speeds, of which the highest is 68 feet per minute. Of course, the eight-spindle speeds include the two back-gear speeds, which are produced through gear ratios of 5¼ to 1. Naturally, the machine with variable speed motor drive may be made to offer more than 24 combinations.

One of the most interesting features of the machine is the headstock spindle, which is furnished either solid or bored, as specified. When it is fitted with a face plate, it takes a No. 5 Morse taper (as does the tailstock). This spindle is bored only when it is to be used in taking nosing operations. A one-inch hole passes through the entire spindle. This makes it tubular, and adds very much to its stiffness, reducing weight at the same time. At the face plate end, a larger hole is recessed into it in a way that provides: First, sufficient depth for any length of shrapnel shell having a diameter within the machine's capacity; secondly, sufficient bearing surface for the chuck jaws, assuring an absolutely tight and vibrationless grip, without digging into the stock; thirdly, the required amount of protrusion beyond the chuck jaws to permit complete nosing with one setting; and, fourthly, minimum overhang beyond the chuck, which prevents chattering and assures smooth, accurate work.

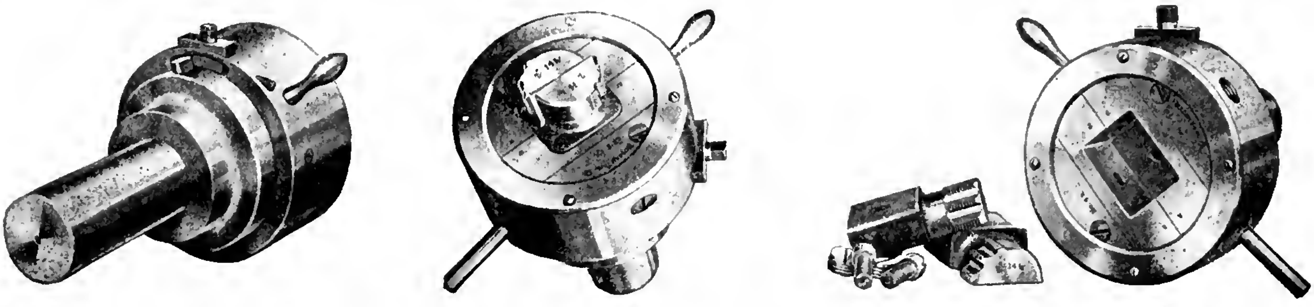
NOVEL COLLAPSIBLE TAP

THIS collapsible tap has been developed by the Modern Tool Co., Erie, Pa., and is designed to meet all requirements of internal threaded work.

As will be observed in the illustration, the tap proper is formed in two halves, being similar to an ordinary solid tap split along the centre line. Instead of having grooves cut at equal intervals around the body, the grooves are confined to opposite sectors of the two halves and are made fewer in number. The shanks of these tap-chasers, as they should be termed, terminate in the form of a square of generous proportions. These square ends are made a push fit in

the recess formed in the chaser blocks which slide in opposite directions, each block moving its chaser across the face of the other chaser.

By confining the cutting teeth to a suitable portion of each chaser, the device immediately assumes all the characteristics of a collapsible tap, the blank surface on each chaser allowing them to be brought toward the centre to withdraw the teeth from the thread. The chaser-blocks slide in a tap head which in turn is driven in a positive manner by the shank. The action of the mechanism is controlled by a cam ring and suitable means are provided for automatic release, resetting, and adjusting to size.



"MODERN" ADJUSTABLE COLLAPSING TAPS, SHOWING FRONT AND REAR, ALSO TAP WITH CHASERS REMOVED.

This tap is suitable for use on the various makes of screw machines, turret lathes and other tools where the tap is stationary and the work revolves. It can also be applied on machines where the work is stationary and the tap is revolved, a simple device for closing the tap automatically as it revolves, being easily attached.

The "Modern" collapsible tap is built in four sizes having a range as follows:

No. 1, having a capacity from ½ in. to 1 in.

No. 2, having a capacity from ¾ in. to 1⅜ in.

No. 3, having a capacity from 1¼ in. to 1¾ in.

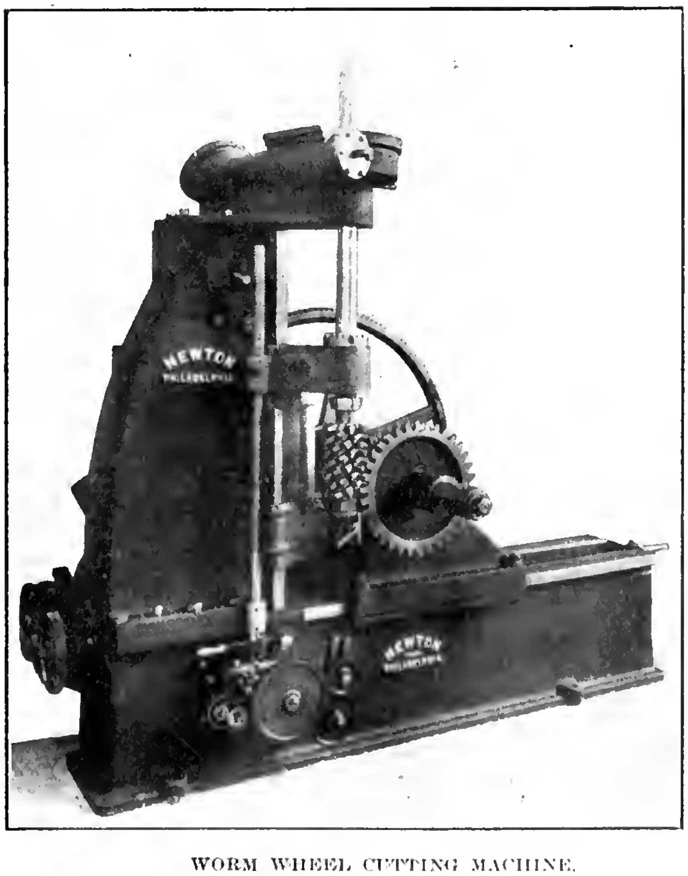
No. 4, having a capacity from 1¾ in. to 3 in.

WORM WHEEL CUTTING MACHINE

THE accompanying illustration shows a new worm wheel cutting or generating machine now being placed on the market by the Newton Machine Tool Works, Philadelphia, Pa. The wheel is cut by either fly cutters or a taper hob. The cutter or hob has the form of a tap and is set to the same distance of axis between worm and wheel and the same angle to the plane of wheel at which the worm actually runs. These measurements remain unchanged during the entire process of cutting.

Contrary to the practice generally followed to cut the teeth of wheel gradually deeper by feeding the cutter in a radial direction to the wheel centre, the cutter in this process is fed at a tangent to the circumference of the wheel, thus cutting first with the tapered end into the solid metal. The teeth of the wheel will become gradually deeper as the cutter, while being fed across the surface, grows larger in diameter, the full end finishing the teeth.

A large worm wheel having 92 teeth, triple lead, 47½ inches outside diameter, 5½ inches face, and of 2 diametral pitch was cut in ten hours.



WORM WHEEL CUTTING MACHINE.

INTERNATIONAL NICKEL

IF the Germans are not securing all the Canadian nickel they want direct, they are not neglecting any ways by which they may secure it indirectly. Mr. Cochrane, a New York millionaire, had built for him the finest and largest power yacht afloat at a cost approaching a million dollars. The hull was an experiment in yacht building, being composed of monel metal, a nickel compound put on the market by the International Nickel Co., and named after its president, Ambrose Monel. Hundreds of tons were used in the construction. Unfortunately it proved a failure. The metal would not withstand the action of the salt water, and after about three months the yacht leaked so badly that Mr. Cochrane sent it to the scrap heap in Boston. As it was being broken up, two Germans arrived from Washington and began negotiations for its purchase. Arrangements were made for repairing the vessel and the adding of large additional quantities of nickel wherever possible. The agent explained that the matter had been discussed at Washington and began negotiations for its purchase. Arrangements were made for repairing the vessel and the adding of large additional quantities of nickel wherever possible. The agent explained that the matter had been discussed at Washington, and it was arranged that, being an American pleasure yacht, it could cross the ocean under the Stars and Stripes, and sail into a German port with an American crew without interference from the Allies. The boat in question is the largest sailing yacht afloat, and undoubtedly hundreds of tons of nickel could be worked into the hull and used as ballast and for other purposes, and thus evade the scrutiny of British and French naval scouts. How much more Canadian nickel may have got to Germany by these indirect methods it is hard to say.

London, Ont.—The city council have decided to purchase five machine guns at a cost of $5,000.

How to Keep Men in Your Employ? A Possible Solution *

By W. A. Grieves **

The necessity of hiring an extra percentage of help in order to maintain the required number of men up to a proper standard is and always has been a source of considerable loss to large employers of labor. The writer clearly explains how one firm avoided this loss and at the same time contributed not a little to the material welfare and happiness of employees.

If you are a manufacturer employing 2,200 men and are shown that it costs you, on an average, about $88,000 more each year than it should, to maintain this force, you are at once interested. At the Jeffrey plant, methods have been adopted for meeting this problem with favorable results and the principles that have been applied can be adapted to other concerns.

Thinking our experience might be abnormal, we sent letters to 40 manufacturing concerns, in the middle west. This letter told how we had been able in five years, by adopting different methods, to reduce the cost of maintaining our force by $24,000 per year.

Fifty per cent., 20 firms, replied and gave their experience for the past year. Others wrote that their experience had been so bad, they felt diffident in putting it upon paper. The replies of the 20 firms revealed that to keep an average force of 44,000 men at work, during the year. they had employed 69,000 men.

Why Men Quit

If more care and thought were exerted to find out why men quit their jobs so frequently, this condition could be improved, and there would be a larger balance on the credit side of the ledger at the end of the year. A certain percentage of any force will change, including loss by death, 1 per cent.; by sickness, 5 per cent.: through removal, 10 per cent., and through mistakes in selecting the right man for the right place, 25 per cent. To maintain an average working force of 44,000 men. taking the foregoing percentages, only 18,000 should have been hired. Instead, 69,000 were hired. or 51,000 more than can be accounted for.

To arrive at the financial loss, group the employes into the following classes:

1—Highly skilled mechanics.
2—Semi-skilled mechanics.
3—Helpers and handy men.
4—Laborers.
5—Clerks.

Then distribute the cost as follows:

1—Expense of employing.
2—Time loss in giving instructions.
3—Breakage of tools and machinery by new men.
4—Spoiled work.
5—Decreased production.

Analyzing these five divisions, their cost in dollars is secured. The clerical work in hiring and discharging men is the least expensive. This cost can be placed very conservatively at 50 cents per man. The instruction expense depends largely upon the nature of the work and the skill and experience of the new employe. The unskilled laborer will cost from $1 to $2 each, for instruction. Experiments in our machine shops show that $10 is not too high for the average skilled mechanic. It is reasonable to figure the expense for semi-skilled men at one and a half time this amount. Helpers and handy men will require at least $5 for instruction; while training new clerks will add a few more dollars. Experience shows that the total cost of instruction can be conservatively placed at $20 per man.

The cost of increased wear and tear and damage done to tools and machinery is difficult to determine, but is about $1 for the highly skilled mechanic and from $7 to $10 for helpers and handy men, an average of $7.

Loss due to reduced production is undoubtedly the largest item. Our experience has been, that mechanics after six months in our employ will gain an average of three to five hours' time per day, while the average new mechanic takes from one month to three months to be able to meet the time limits. At the average wage of 35 cents per hour, the old men gain four hours per day. At 50 per cent. of the day rate, the gain is 70 cents per day. As these men have also saved a like amount for the company, in one month of 24 working days, the company loses $16.80 per man. If the average period during which time is lost by the new men is placed at two months. the loss totals $33.60 per man for decreased production.

The expense incident to spoiled work also is hard to get at, but is at least $15 for skilled and semi-skilled mechanics and $5 for handy men and helpers.

These losses total $81.10 per man. To be conservative, reduce this to $40 per man average. For each of the 20 firms, averaging their employes at 2,200 men each. this means $88,000 of unnecessary expense, or $1,760,000 for all of them. And we have not counted the increased overhead. These figures clearly indicate the need of greater stability of employment in our industrial institutions.

Salesmen vs. Workmen

Industry is composed of two major divisions, producing and selling. What has been your attitude toward the inefficient salesman? In some cases you discharge him. Generally you are no better off. In replacing him, you take the same chances of getting one just as inefficient. Therefore, you reason that the best solution is to educate the salesman. Why not do the same in the manufacturing departments?

The first plan of attack should be through education. The better educated a man is, the more ground for believing that he can be reasoned with. As an example, while conversing with one of our best paid and highly skilled mechanics, recently, he remarked that the company must make an enormous profit on a certain product. Material and labor costs were the only two elements he had considered. Of the immense overhead burden, such as sales, expense, supervision. upkeep, insurance, interest on investment, advertising, etc., he was entirely ignorant.

Is it any wonder that such men fall easy victims to the misleading arguments of the selfish and unprincipled labor agitator? The trouble rests with the manufacturers. They have allowed themselves to be advertised by those who do not know — allowed themselves to be shown wrong side up.

Do your men know that if you make money this year. it probably will go into new machinery and equipment next year? Do they know that through changes in design, this new machinery may be good only for the scrap heap next year? Do they know that during periods of depressed business, you are compelled to take work below cost, simply to give them work and hold your organization together? Do your men know that while you are eager to pay higher wages. provide better equipment, and have more ideal working conditions, you are restrained by competition? You are willing to pay $5 per day to mechanics, but others may pay only $3 per day. Do your employes know this?

In the Jeffrey betterment policy, we

INDUSTRIAL SIGNIFICANCE OF MODERN ENGINEERING DISPLAYS

THE Panama-Pacific Exposition is now entering on the final stage of its career. The success which has attended its limited life is as gratifying as it was unexpected. In spite of the seeming lack of support accorded it by foreign governments, on whose active participation in the event considerable expectations had been built; in spite of the war, which has so absorbed the thoughts of all nations, that the event which the Exposition celebrates—the opening of the Panama Canal—was relegated to the background of international affairs until its very existence seemed largely forgotten; in spite of these and other adverse factors of the situation, the Exposition has not only proved a successful event from a popular and spectacular point of view, but according to latest available reports the receipts have enabled provision to be made for all financial liabilities, so that from now on till the closing day, the Exposition has simply to pay its way. Judging from events still scheduled to take place, interest in the show ought to continue unabated.

Looking at the Exposition from an engineering point of view, one finds many features which mark a decided difference from previous and similar undertakings. The most peculiar feature and one which appeals with sudden force when its possible significance is fully realized, is the fact that for the first time on record, steam has been discarded as the source of power for the many exhibits in motion.

Internal combustion engines not only form the source of power, but, to the careful observer seem to surpass in interest, if not in magnitude, the magnificent displays so effectively staged by electrical corporations.

Wonderful may be the developments, and numerous the applications of electricity, but a point which should not be lost sight of is the fact that electricity is simply a form of energy, easy of transmission, application and control, but always dependent on some supply of mechanical energy for its creation.

Many parts of Canada are bountifully endowed by Nature with water power, which has been so developed for electrical purposes, that we give less thought to our electrical than to our water supply. On the other hand, people are apt to overlook the fact that while water in itself costs nothing, the utilization of the potential energy in water can only be accomplished in the highest degree by operations of great magnitude.

The remarkable degree of efficiency attained by internal combustion engines with low grade fuel is not confined to units of large size. Economy of operation comparable with modern hydro-electric plants is now obtainable with relatively small plants, and the possibilities of future oil developments in parts of the Dominion not too well favored with water power give to this type of engine an interest of more than passing moment.

While the absence of steam plant exhibits at San Francisco is perhaps due to a combination of geographical and commercial circumstances, the fact that there is a scarcity of such exhibits only intensifies the feature referred to.

The Canadian National Exposition which recently closed its doors after its 36th annual occurrence has not always featured engineering displays in a manner commensurate with the importance of either the event or the industry. At the present moment, and for a considerable time to come, the engineering firms of Canada will form one of the principal mainstays of the Dominion, if not the Empire. Future industrial developments demand that we be thoroughly familiar with every economic aspect of power generation and the various apparatus therefor. In the reconstruction of European industry our manufacturers will find ample opportunity for renewed activity, and the consistent education of power users should have careful consideration at the hands of our exhibition authorities.

Every encouragement should be given to manufacturers to exhibit both machinery and prime movers under actual conditions. The long delayed Machinery Hall should be provided at the earliest possible moment. The lack of suitable facilities for proper display has deterred many of our leading manufacturers from exhibiting in the past. A Technical Committee with power to negotiate suitable exhibits well ahead of time would eliminate many of the eleventh-hour efforts which are at present of yearly recurrence, and a combined display of machinery and manufacturing processes in an adequate manner would be attended with desirable results to exhibitors and authorities alike.

SELECTED MARKET QUOTATIONS

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., Sept. 27, 1915.—The recent favorable news from the front has had a cheering effect in business circles and will assist materially in stimulating business. The manufacture of shells is proceeding in a satisfactory manner, and it is generally believed that further contracts will be placed at no distant date. The manufacture of field guns is being contemplated, but nothing has been done beyond making preliminary investigations. A committee has been apointed to look into the matter.

Steel

Steel, as usual, is still holding the central position in the market, as the demand, both for bars and billets is still heavy. The demand for shells seems as urgent as ever and with the prospect of larger shells being manufactured the steel makers will be kept busy for some time to come. With the possible advent of gun making having the attention of the Canadian manufacturer, the steel industry will necessarily have to face a new problem in producing the required raw material.

Pig Iron

Quotations on pig iron remain firm, there being very little change in the situation. There has only been a moderate turnover during the week, the strength of the market being due to the sales already made.

Machine Tools and Supplies

The machinery outlook for the week is little changed. Deliveries are still very backward for certain tools, especially those required for the production of high-explosive shells.

That new possibilities for the machine tool builder are becoming evident, is the fact that steps are now being taken to see what can be done in the making of field guns for the Allied Governments. The manufacture of these guns would create a demand for new and heavier types of machine tools and would tax the resources of the tool manufacturers. There would also be a bigger demand for small tools and attachments.

Metals

Quotations on the different metals show little change over those of the previous week. Prices are holding firm with the exception of antimony, which shows a slight decline.

Old Materials

Several fluctuations have been noticed in the scrap prices during the week. The present price of wrought iron scrap is $2 per 100 lbs. higher than a week ago; machinery scrap iron shows an advance of $3 and scrap zinc $2, while a decline of 20 per cent. is shown in heavy lead.

Toronto, Ont., Sept. 28.—The remarkable development in the export trade of Canada is shown in the returns recently issued by the Department of Trade and Commerce. In August alone the export of manufactured goods reached a total of over two million dollars, practically double that of the corresponding month last year. This heavy increase is largely attributable to the heavy output of war munitions. The returns of the export trade for the five months of the present fiscal year show a total of over two hundred million dollars, representing an increase of fifty million dollars. The value of imported goods shows a falling off of about four million dollars.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

While the above condition is distinctly beneficial to the Dominion, the full effect has not yet begun to be felt. The domestic trade is still comparatively quiet, although a more optimistic spirit prevails in business circles. There is, generally speaking, a feeling of returning confidence, due to the large crops and encouraging trade returns.

The steel trade continues very active, due to the heavy demand for steel for munitions. The outlook in the trade was never better. The demand for machine tools has fallen off, on account of there being no new orders for shells placed recently. It is, however, confidently expected that there will be a revival of business at no distant date. There is little of interest to note this week in the metal markets. The trade is awaiting developments in the sterling exchange situation. The scarcity of aluminum is becoming more pronounced and prices have made a sharp advance. Apart from this the markets are steady.

Steel Market

The market is very firm, and the mills continue to do big business. The demand for steel for munitions is so great that Canadian firms have been obliged to import billets and steel rounds from the States, notwithstanding the fact that some of these concerns have recently increased their producing capacity. Prices are holding very firm, and an advance in bars may be announced at any time. The demand for steel, other than for shells, and export trade, is light.

The high-speed tool steel situation continues to cause considerable anxiety to consumers owing to scarcity and advancing prices. Stocks are getting lower, and the demand is becoming heavier. The Vanadium Alloys Steel Co., of Pittsburgh, announce a further advance of 15c per pound, while other markers have also been obliged to raise their prices. Makers in Sheffield, England, are having the greatest difficulty in supplying their Canadian customers on account of the heavy demand in the home market. Prices of galvanized sheets are easier owing to the downward tendency in the spelter market. Sales are not very heavy, largely due to the mills refusing to sell for extended delivery. Prices of black sheets are firm, and there is a tendency towards higher prices.

Heavy export business is becoming a more dominant factor in the steel trade in the States than at any time since the beginning of the war. Large orders for bars for shells are being placed and deliveries are running into next year, being practically unobtainable this year. Prices are very firm, and the market generally has an upward tendency. There is a big demand for billets, and prices are naturally advancing. Bessemer and open-hearth billets have advanced again, and are being quoted at $24.50 and $25 respectively.

Pig Iron

There is practically no improvement in the foundry pig iron situation, and foundries are moving cautiously in buying for future requirements. Prices have advanced and Hamilton and Victoria brands are being quoted at $20.50 per ton.

Machine Tools

The demand for new tools has fallen off considerably, due to the lack of new shell orders, and also the difficulty of obtaining new machinery. Makers are in a sold-up condition, and deliveries are as backward as ever. This situation has resulted in a demand for second-hand equipment, although even in this case business has fallen off to some extent. Inquiries now are principally for tools for making shell parts, and quite a number of second-hand tools have been sold recently for making that part of a shell called a "Gaines."

Supplies

Business continues good and prices firm. Prices of high-speed steel cutters of all descriptions have been withdrawn on account of the difficulty in obtaining raw material. Boiler and structural rivets, 3/4 in. and larger, have been advanced from $3.25 to $3.75. Solder, half-and-half, has declined 1c, and is now quoted at 23c per pound.

Metals

The markets are firm and prices steady, with the exception of aluminum, which has made a sharp advance. The entire market is awaiting the outcome of the loan negotiations now being carried on between representatives of the British and French Governments and American financial interests in New York. The market is being affected by the sterling exchange situation, and it is generally believed that the situation will improve considerably if the price of the pound sterling rises to a more normal basis. Business conditions locally are unchanged, the principal demand being for metals for munitions.

Tin.—The market is firm, with an upward tendency in London. There is, however, comparatively little interest being shown in either spot or future deliveries. The market is being adversely affected by the sterling exchange situation. Local quotations are unchanged at 39c per pound.

Copper.—The market is still awaiting the big buying movement, which showed some evidence of starting about three weeks ago. Production of copper at the present rate is believed to be in excess of consumption, and hence it is believed that buyers of the metal are better able to hold off and purchase only for immediate needs than they were a few months back, owing to the heavy demand for copper for munitions. There is every probability of an increase in consumption when the sterling exchange situation improves. Quotations for copper locally are unchanged at 19c per pound.

Spelter.—The market is stronger with the possibility of higher prices. Consumers are taking more interest in spot and near-by positions, but the demand is not heavy. Quotations are unchanged at 18c per pound.

Lead.—The market is firm and unchanged. The "Trust" price of $4.50 New York is being maintained, and it is generally believed that this will hold steady for some time. Local quotations are unchanged at 6¼c per pound.

Antimony.—The market is dull and featureless. Quotations are unchanged at 35c per pound.

Aluminum.—Supplies of this metal are becoming more difficult to obtain, and with an increasing demand the situation may be said to be acute. Quotations have advanced 15c, and are entirely nominal at 55c per pound.

St. John, N.B., Sept. 25.—Local industrial conditions continue to be satisfactory, the only effects of the war so far as can be noticed, being the absence of new building enterprises, though as regards the volume of trade with most houses it goes along in a steady and encouraging manner. Collections throughout the province are fair. The lumbering season has been better than was generally anticipated last spring. Fishing, particularly along the North Shore, has been exceptionally good, and except in some quarters, the crops have been well up to the standard. Thus it follows that manufacturers are finding at least a good home market, and few complaints are heard as to the falling off of business. It is not so good, of course, as if there had been no war, but all things considered there is no reason to grumble. The orders for war supplies have also been an important factor in Maritime Province towns and cities, and have helped to keep many men employed. There promises to be considerable shipping from Halifax and St. John this winter, and at the latter port the C. P. R. are now seeking extra accommodation.

A new flour mill is to be built at Newcastle, N.B., to cost in the vicinity of $6,500. Its capacity will be one barrel an hour. The matter has been decided upon favorably by the Board of Trade, and a committee composed of Hon. John Morrissy, Secretary E. A. McCurdy and John Betts have been appointed to look into the matter and report back. About fifteen million feet of lumber on the dock yard of the Bathurst Lumber Co. at Bathurst, N.B., were destroyed in a fire there this week. The lumber was valued at $250,000, which was well covered by insurance.

The expectation is that early in October the street cars will be crossing the new spandril arch bridge across the Reversing Falls, St. John, N.B., just recently completed. A diamond crossing has been ordered and the plans are about completed. The old Suspension Bridge has been dismantled and removed by men under Contractor McVey. The granite blocks are being taken to Moncton for use in the new bridge there. The death of a well-known business man of St. John occurred this week in the person of Frank H. Foster, aged 62 years. He was secretary-treasurer of the Canada Brush Co., of St. John and had been one of its promoters. Mr. Foster was also head of the wholesale firm of Foster & Co. He was particularly well known throughout Eastern Canada and very highly respected.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Atache, Russian Embassy, Washington, D.C.

A POSSIBLE STEEL FAMINE

THE First National Bank of Boston, Mass., in a recent letter, says:—

"Although a brand new furnace may be blown in here and there, it takes a year or two to make a general increase in steel-making capacity. This question is being discussed because authorities in the trade announce that the steel industry is running almost at capacity—that it is from 60 to 90 days behind in deliveries, especially on bars, and that it is sold out through 1915 with contracts offering for 1916. It is even hinted that a famine in steel will develop in 1916 if the present trend continues. Moreover, it is pointed out that the railroads have not been in the market for equipment since 1906; and that they will be driven in by the existing activity and this time for heavier equipment than has ever been known. For example, the Pennsylvania is ordering a 140,000-pound 'Dreadnought' freight car—the heaviest ever constructed, which will necessitate either all steel wheels or a 6-wheel truck, and may ultimately lead to a heavier rail, heavier trestle, and freer use of heavier steel throughout. Buying of this character by the railroads might prolong the revival in steel over years.

"Analysis of the steel trade shows a somewhat peculiar condition. At the bottom of the boom is, of course, the war orders. It is probable that export business in steel takes up from 40 to 60 per cent. of present production. Domestic business lags; car building is comparatively light as yet; new construction of buildings requiring structural steel is sub-normal; and only a few more rails have been bought in 1915 than in 1914. The automobile industry is about the only domestic consuming steel line which

is fully active. Despite the lack of domestic steel consumption, the trade is reported full and sold out. On the basis of contracts received, the steel trade is probably sold out as stated, but October is awaited as the test month of the genuineness of the boom as regards specifications and production—March and October being the best steel months of the year."

CANADA'S TRADE STATEMENT

A FAVORABLE showing is made in Canada's trade statement for August and for the five months of the fiscal year ended with that month. The total trade in merchandise in August was $81,926,976 against $75,901,335 in the corresponding month, an increase of six million. In the five months of the fiscal year the aggregate was $375,824,612, as against $364,197,801, an increase of eleven millions. Imports in August were $40,832,822, a falling off of four millions and exports $41,094,154, an increase of ten millions. Total imports in the five months were $175,562,199, a decrease of forty millions, while the exports were $200,262,413, an increase of fifty millions.

Various Exports

The export of manufactured goods in August was $10,690,464, practically double that of last year, while for the five months they were $62,231,845, as against $26,728,965. The marked increase is largely attributable to the heavy output of war munitions.

Agricultural exports in August totalled $6,895,726, a falling off of half a million, while for the five months domestic agricultural exports were $48,207,048, a decrease of two millions.

Mineral exports totalling $6,090,370 increased in August by a million and a half and in the five months by three millions. Animals and animal products likewise show an increase. In August the total was $9,193,103. Forest products exported in August were $5,846,890, an increase of a million and a half. In the five months the total was slightly over twenty-two millions, an increase of three millions.

Duty Collected

The total duty collected in August was $8,431,565, an increase of $70,000 over August of last year, while for the five months it aggregated $36,514,037, a decrease of $300,000.

It is apparent that the extra duties, designed to keep the revenue abreast of the ante-bellum period are accomplishing that purpose.

The Dominion Stamping Co,. Walkerville, Ont., will in future be known as the Dominion Forge and Stamping Co.

CANADIAN COMMERCIAL INTELLIGENCE SERVICE

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Comissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

Producing Fuse Sockets and Plugs for Shrapnel Shells

Staff Article

The problem of how to produce to specification a satisfactory article of high-degree accuracy, and yet at a price low enough to be consistent with the temporary nature of the service required, is well instanced in the manufacture of sockets and plugs.

THE observations and impressions derived from an hour or two spent in a small factory manufacturing the component parts of the finished shrapnel shell give to the thoughtful mind a clearer conception of the energy and resourcefulness of the average Canadian manufacturer when the time comes for him to develop to the utmost the equipment at his command.

The speed with which this productive power has been brought to the highest point of efficiency shows the determined interest and sterling qualities of both the manufacturer and the various artisans required to produce the necessary results.

One of the features of this great movement which is worthy of commendation is the co-operation of effort among many manufacturers to reduce to the minimum the delay often necessary when equipment is required for the completion of one or more parts of a much needed article. Often a manufacturer may be able to accomplish the required result with the exception of one operation. To do this operation it may be necessary to install expensive machinery; but if this operation can be performed in another establishment within a reasonable distance, the co-operation of these firms along the desired lines may mean much to the final outcome, as well as mutual benefit to themselves.

In the manufacture of shells, both shrapnel and high explosive, many component parts are required which necessitate their production in separate plants to those equipped for the making of the shell body. In producing the fuse sockets and brass plugs which form the nose of the finished shell, one of the necessary requirements is the brass foundry.

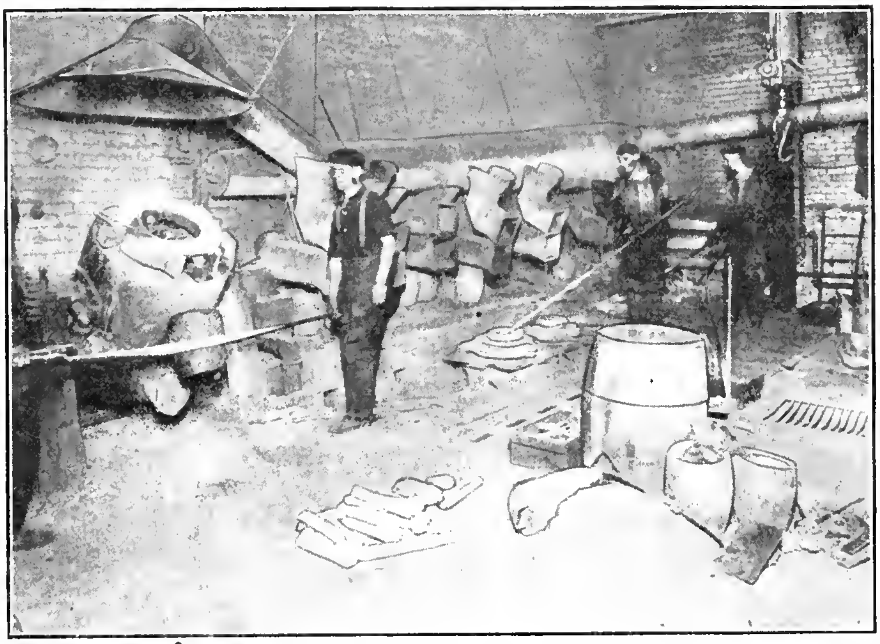

FIG. 1. CRUCIBLE SECTION OF BRASS FOUNDRY WHERE SLUGS FOR FUSE SOCKETS ARE PRODUCED.

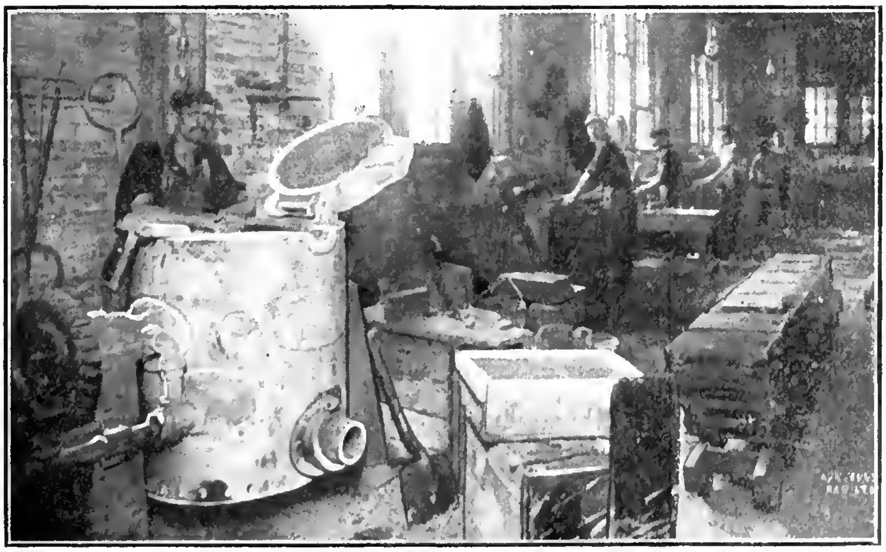

FIG. 2. FUSE SOCKET PRODUCTION IN THE FOUNDRY.

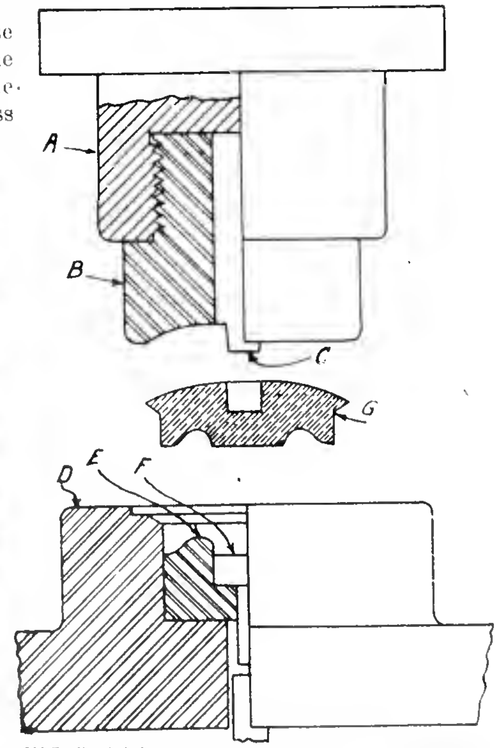

FIG. 5. DIE FOR FORGING BRASS PLUGS.

The subject matter of this article was obtained from observation and impressions derived from a visit to a plant, which for years has been employed in the production of gas and electrical fixtures, as well as filling orders for a large variety of brass and aluminum articles.

Casting the Slugs.

Fig. 1 shows a view of the foundry where the slugs are cast before the forging operation. In this picture is shown

the crucible section where the various metals are melted before pouring into the moulds. At the extreme right and also at the left are two crucibles which have a capacity of 500 lbs. apiece; another of these is shown in Fig. 2, which is being repaired. Beside these three, there are ten others beneath the floor, each having a capacity of 150 lbs. These furnaces (of natural gas) are in operation at present 24 hours a day, metal being poured off at intervals of 15 or 20 minutes, day and night. The composition of this metal for the fuse sockets

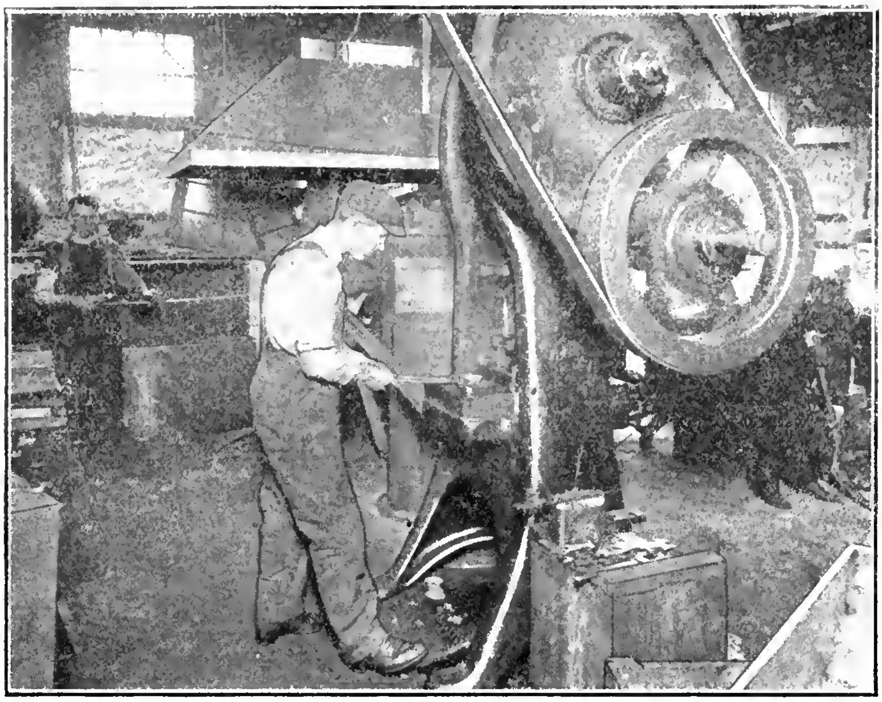

FIG. 3. POWER PRESS FORGING SLUGS INTO FUSE SOCKETS AND PLUGS.

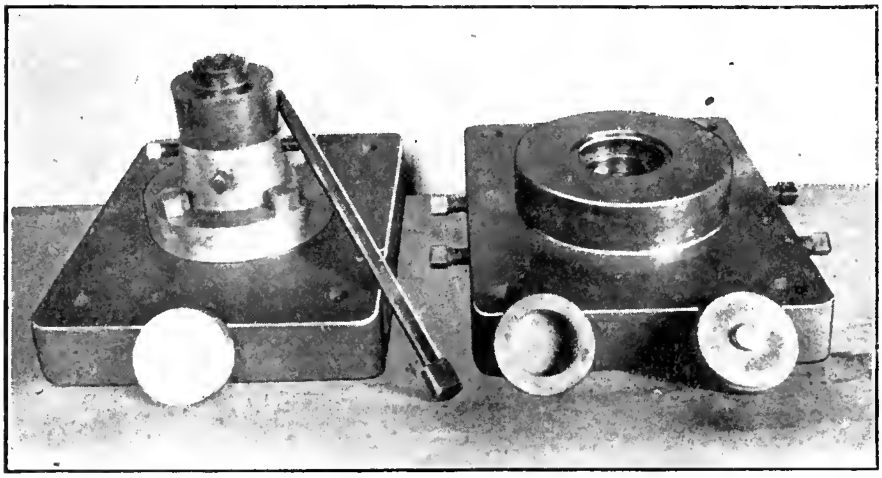

FIG. 4A. DIE FOR FORGING BRASS SOCKETS.

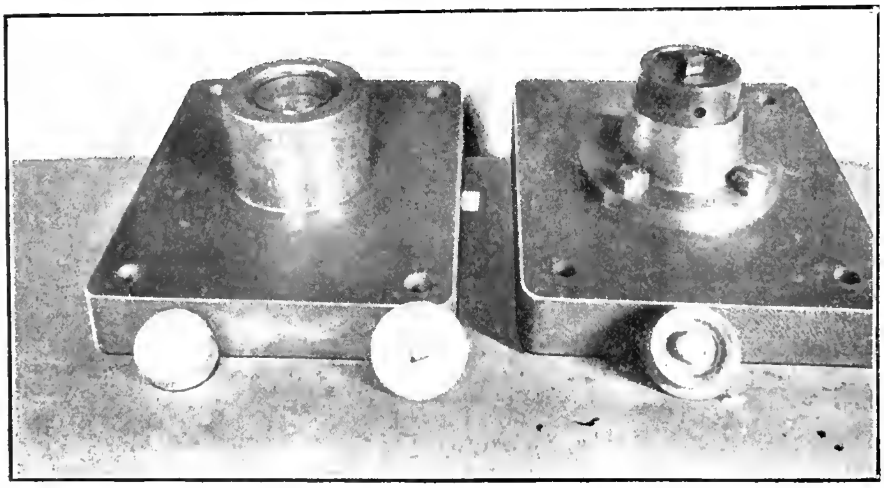

FIG. 5A. DIE FOR FORGING SOCKET PLUGS.

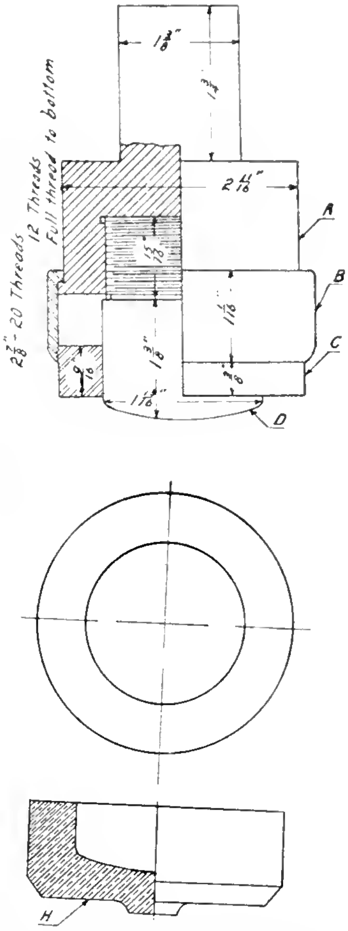

SECTION OF SOCKET AND DIE.

is 40 per cent. copper, 58 per cent. zinc, and 2 per cent. lead.

Fig. 2 shows a view of the floor and benches where the metal is poured into the various moulds previously prepared.

Forging Fuse Sockets and Plugs.

After the slugs are sufficiently cold to be removed, they are shaken out and gathered up and taken to another factory some distance away, who have a

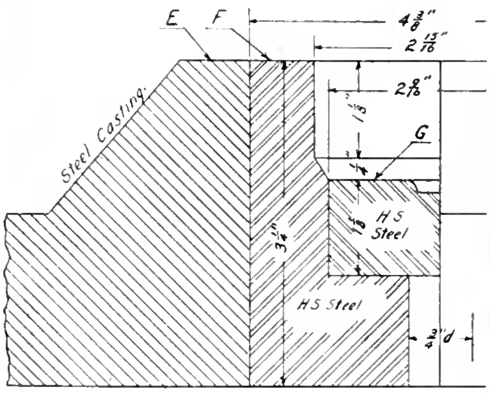

FIG. 4. DIE FOR FORGING BRASS SOCKETS.

press suitable for forging these slugs into the desired shape.

This operation is shown in Fig. 3. In the background is the furnace where the slugs are heated to a cherry red and passed to the man at the press by means of the trough shown. This operator places the hot slug into the die and the punch upon descending forms the piece into the desired shape. The construction of these dies is shown in Figs. 4 and 5, Fig. 4 being the die for the sockets and Fig. 5 the die for the plugs. A view of the finished forging is also shown with each die; also shown in Fig. 4a and 5a.

Machining Sockets.

The first machining operation is performed on a Warney & Swasey turret machine. The cycle of operations is chucking, drill bore and face, undercutting, tapping, finish face and ream. At periods during these operations a blast of air is forced into the recess to remove surplus cuttings; this is shown in Fig. 6.

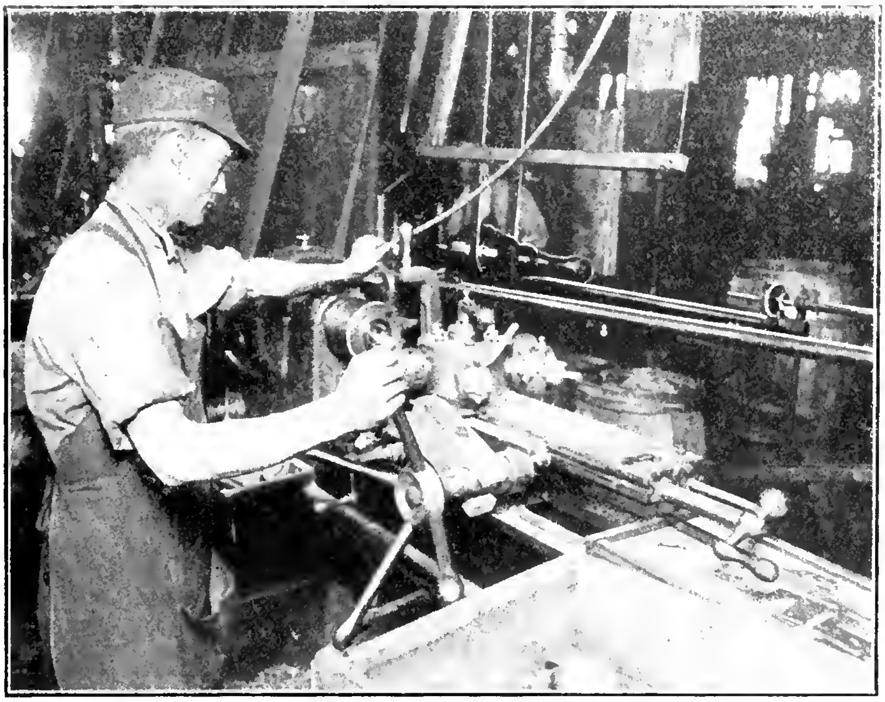

FIG. 6. FIRST MACHINING OPERATION ON FUSE SOCKETS.

The second operation on the fuse sockets (also done on a Warney & Swasey turret machine) is the finishing of the side which screws into the nose of the shell. This operation is shown in Fig. 7. The cycle of operations is chucking, roughing from the back, finishing from the front, and threading with the die. The sockets are then drilled and tapped for a small screw used for locking time fuse in position; they are then retapped to the finished size.

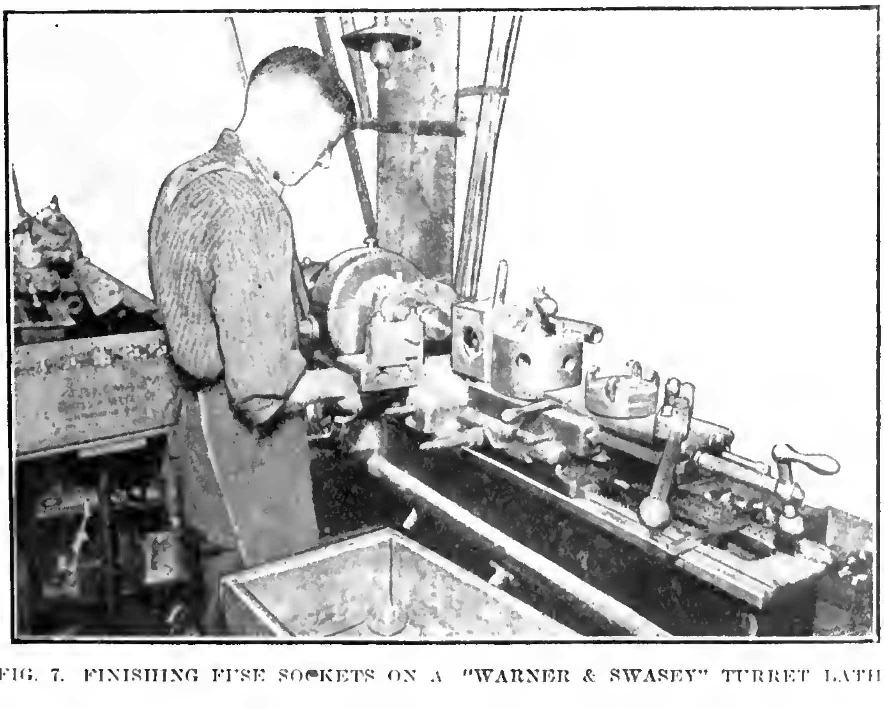

FIG. 7. FINISHING FUSE SOCKETS ON A "WARNER & SWASEY" TURRET LATHE

Machining the Plugs.

The work on the plug is done at one setting, the cycle of operations being chucking, roughing, undercutting and threading. This operation is shown in Fig. 8. These plugs are used to protect the fuse socket during the period of transportation, after which they are replaced by the timing fuse.

HOW METAL COOLS FROM LIQUID TO SOLID

IN the course of a lecture delivered before the Sheffield branch of the British Foundrymen's Association on April 30, Dr. W. Rosenhain, F.R.S. (Head of the Metallurgical Department of the National Physical Laboratory), advanced an interesting theory, the consideration of which might enable one to understand some of the things which happen during the cooling of metals.

Special attention was given to the consideration of the existence of non crystalline or amorphous layers in metal bodies which have been cooled from a liquid condition. The "change of state" which took place during solidification involved something more than the formation of mere crystals commonly understood. Crystals invariably form at right angles to surfaces which happen to be at uniform temperatures, the growth of these crystals beginning at different points of centres termed nuclei where the temperature of the metal first reaches the freezing point. Each of these nuclei or centres then extended in all directions, meeting the arms of other nuclei and causing the crystal growth to permeate the whole body as quickly as the various parts reached the state of solidification, on freezing point.

By a crystalline body was meant one in which the particles, of which the body was composed were arranged in some regular manner. The absence of such a crystalline formation was termed an amorphous state, and science had enabled a very considerable insight to be obtained regarding the manner in which these particles were formed, as well as their absence. The growth of a crystalline structure did not result from the building up of successive layers, but by shooting out branches until these met other branches and the intervening spaces were filled up. What was it that made the atoms of the metal arrange themselves in this way? Clearly there was some directing force which made the atoms turn and arrange themselves.

and determined whether a given atom should adhere to one crystal or to another. It would appear that the attractive force acting on the atom from one crystal was greater than those acting upon it from another.

The Amorphous Theory

But ultimately a point must be reached between two growing crystals where the opposing forces of the crystal growths were nearly balanced and the atom was not impelled very strongly one way or the other, and therefore did not range itself definitely on either side. The effect of the two such opposing forces was very clearly illustrated in the attraction of iron filings by the two similar poles of a magnet (as shown by means of a slide) between which there was a distinct neutral ground where the two opposing sets of forces were so nearly balanced that the particles of iron arranged themselves in a completely indifferent manner. So in the case of a cooling mass of metal, there would be a neutral zone between any two crystals where the atoms would go on cooling down without arranging themselves in crystalline order. This amorphous or non-crystalline layer between the crystals of metal would have the hardness characteristic of all under-cooled materials. The behaviour of pure iron which would consist of crystals of iron, with amorphous layers between, was considered. The amorphous layers would be stronger and harder than the crystals themselves, and if strained or deformed there should be very little movement at the boundaries of the crystals, all the movement taking place within the crystals themselves. Slides were exhibited which showed that deformation of the body as a whole was accomplished by deformation of the crystals themselves.

A temperature of 900 deg. Cent., however, approached somewhat to the softening point of the amorphous layers, while the crystals melted suddenly and changed from the solid to the completely liquid at a much higher temperature. At such a temperature as 900 Cent., nearly all movement took place by the sliding over one another of the boundaries. Thus the flow of these metals at high temperatures obeyed the law of the flow of various liquids. To carry the process a little further, the deformation might be continued until rupture took place; in the cold metal the crystals broke across but at a suitable high temperature the crystals could be pulled apart from one another quite easily, so that the fracture followed the crystal boundaries. Several slides were shown illustrating the varying course of the fractures at different temperatures, with various metals, including purest gold, to show that the action was not attributable to the presence of impurities, as was sometimes suggested by opponents of the theory which was also confirmed by experiments in vacuum.

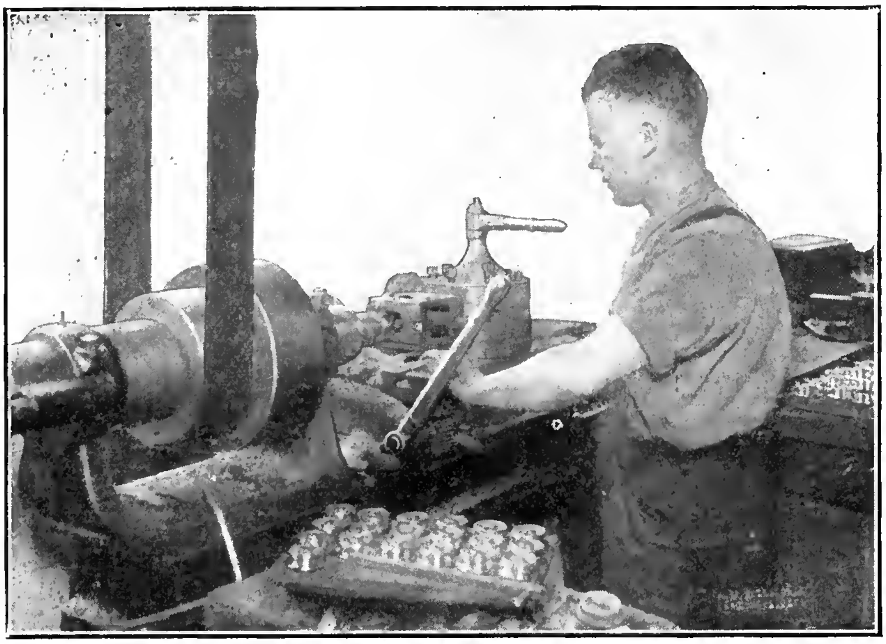

FIG. 8. FINISHING BRASS PLUGS ON FLAT TURRET LATHE.

Experiments in latent heat also, in the opinion of the lecturer, clearly indicated differences which would be very hard to explain on any other physical ground. He was quite prepared to admit that there was no definite proof of the existence of this "amorphous cement," but some people would never be convinced until one could hit them with a piece of amorphous metal. At the same time he thought there was enough evidence to indicate that there must be something in the theory. It explained the difference in the mechanical properties of metals, which depended upon the size of their crystal structure; and the curious difference in their elastic limit was very readily explained by it. It also served to give a reasonable explanation to that most puzzling of all facts, that a very small proportion of impurities produced such enormously disproportionately large mechanical, electrical and other effects; these added bodies would always tend to concentrate themselves in this amorphous cement, and might account for the large effect of vanadium on steel. This, he thought, was one of the most fruitful applications which the theory offered, but a good deal remained to be done in working out these applications; it showed why other things injured steel, because they spoiled the binding power of this amorphous cement. Dr. Rosenhain also discussed the separation of the various constituents of alloys, the formation of solid solutions, and the formation of cores. Cores were due to the rate of cooling; only by a slow cooling could completely homogeneous crystalline aggregate be obtained. The limitation of phosphorus in steel was considered, fissures in shrapnel shells being due in his opinion to regions of low carbon and high phosphorus, resulting in layers of different hardness. The remedy was to eliminate the phosphorus as far as possible, or to render its distribution uniform. One way was to decrease the speed of solidification of the steel, and if that was impracticable, the next best thing was to anneal the steel very drastically at a certain stage in the working.

ZINC DISCOVERED IN NORTHERN QUEBEC

ZINC in large quantities is reported to have been discovered in the vicinity of Burbridge Lake, in the Upper Gatineau district, Quebec, north of Ottawa. Denis Callahan, a Haileybury prospector, recently found evidences of this mineral in that part of the Laurentian hills, and engineers will investigate.

John D. Macfarlane, a mining engineer of Shawville, who was in the capital on his way up to look over the locality, believes it possible that zinc will be found there in considerable quantities. He is familiar with the country, and reports already made indicate that the deposits may prove as valuable as those now controlled by the New Jersey Zinc Corporation in that state. Conditions in the Burbridge Lake district are reported to be similar to those existing where this corporation has its wealthy deposits. Zinc is selling at very high figures just now on account of its use in the manufacture of war munitions.

Autogenous Welding with the Oxy-Acetylene Blow Pipe*

By C. Royer **

Welding by means of the oxy-acetylene process is a method of repair, which can be adopted in connection with almost any description of metal work. The possibilities possessed by it as a manufacturing process have not, however, been fully recognized, and it is in this direction that further future developments of the art are most likely to take place.

THE successful application of autogenous welding in very many instances has proven to the industrial world the great utility of this process. The possibilities of this process are continually being demonstrated in hundreds of workshops, where its successful application in daily work indicates the almost unlimited field of usefulness which the future holds for it.

Electrical, Chemical and Autogenous Welding

Before proceeding with the subject of this lecture, it might be desirable to mention the subject of electric welding. Electric welding consists of the application of electrical energy in such a manner that the temperature of the work will be raised to the desired point in two ways, either by causing the work or certain parts of it to form a resistance circuit and be heated by the effort of the current in overcoming the resistance, or by striking an arc between a suitable electrode and the part of the work to be welded.

In the first case, the two parts to be welded are pressed together, and the current supplied through electrodes on either side of the contact joint, the resistance of which causes local heating of great rapidity, which soon reaches welding point, when the two parts are inseparably united at the point of contact.

*From a lecture given before the Metallurgical Society of McGill University, Montreal.
**Manager of L'Air Liquide Society, Montreal.

PATCH WELDED IN.

Spot welding is the best example of the resistance process, and is very serviceable where large quantities of similar parts are to be handled..

The arc process possesses some peculiar advantages, due to the fact that its rapidity of action serves to eliminate the large amount of expansion and contraction, which in some cases militate against the success of autogenous welding. The successful application of the arc-process depends largely on the type of apparatus, many of which have been designed, but all of which have not proved an unqualified success. The advantages of the arc process are sometimes offset by the changes which take place in the metal, the resulting difference between the welded region and adjacent parts being occasionally very marked in regard to such features as hardness, brittleness, and elongation.

INSTALLING FREEZING COILS WITH WELDED JOINTS IN AN ARTIFICIAL ICE SKATING RINK.

The Thermit Process

This is strictly a chemical process, and depends on the fact that when powdered aluminum is intimately mixed with iron oxide and a small portion heated to a suitable temperature, the aluminum combines with the oxygen and releases the iron. This reaction is accompanied by intense heat, the iron being turned into a molten mass, which is available for use in a welding mould, as used in scoop welding. Although limited in application, its reliability and capabilities render it indispensable in certain classes of repair work.

Blow Pipe Processes

The general use of the blow pipe as a means of welding is of comparatively recent occurrence, but it has firmly established itself as a recognized branch of industrial activity. Its most interesting features are the large variety of work which it can perform, and the number of different metals which can be united by means of it.

Comparatively little expense is involved in the installation of a plant for any particular line of work, while the fact that this process alone is capable of use on cast iron, steel, aluminum, copper brass, bronze, etc., renders it unique among welding processes.

Although several combustible gases

PATCH CUT OUT.

have been proposed for use in the blow pipe, experience has shown that acetylene gas is the most suitable.

BROKEN PRESS FRAME.

Oxy-Hydrogen Flame

The possibilities of oxygen and hydrogen for blow pipe work were first tried out on a commercial scale in 1901. The combustion of hydrogen in oxygen results in the generation of a large amount of heat, 350 British thermal units being released for every cubic foot of hydrogen consumed. At the same time, a proportion of water is formed in the shape of vapor.

Theoretically, two volumes of hydrogen and one volume of oxygen are necessary for perfect combustion. Practically, a flame of such composition is unsuitable for welding, due to the presence of water vapor, which is decomposed by contact with the hot metal; the oxygen combines with the metal to destroy its quality and impair the reliability of the weld. This action may be avoided to some extent by using an excess of hydrogen, in some cases 4 to 1, but this waste is accompanied by a lower flame temperature, so that except for very light sheet steel work the use of the oxy-hydrogen flame is almost discontinued.

Acetylene Gas

The use of acetylene gas had also been proposed in 1901, and its economy of operation, combined with its wide field of application, has resulted in its universal adoption by autogenous welders.

Acetylene is an endothermic gas which gives 1,630 British thermal units per cubic foot, 270 of which are due to the heat of dissociation. By weight, acetylene consists of 92.3 per cent. carbon and 7.7 per cent hydrogen. When one volume of acetylene is burned with one volume of oxygen, carbon monoxide and hydrogen are formed, and burn in the shape of a small bright cone in the centre of the flame. Towards the outer part of the flame these bodies combine with a portion of the oxygen of the atmosphere, presenting a different appearance from the central cone.

While $2\frac{1}{2}$ volumes of oxygen are theoretically necessary to burn one volume of acetylene, only one volume of oxygen need be supplied to the blow pipe, the atmosphere supplying the balance. The large proportion of carbon monoxide and free hydrogen in the oxy-acetylene flame have a reducing action, which renders the flame perfectly neutral and non-injurious to the work.

HEATING WITH BLOW-PIPE TO REMOVE PROPELLER

Autogenous Welding

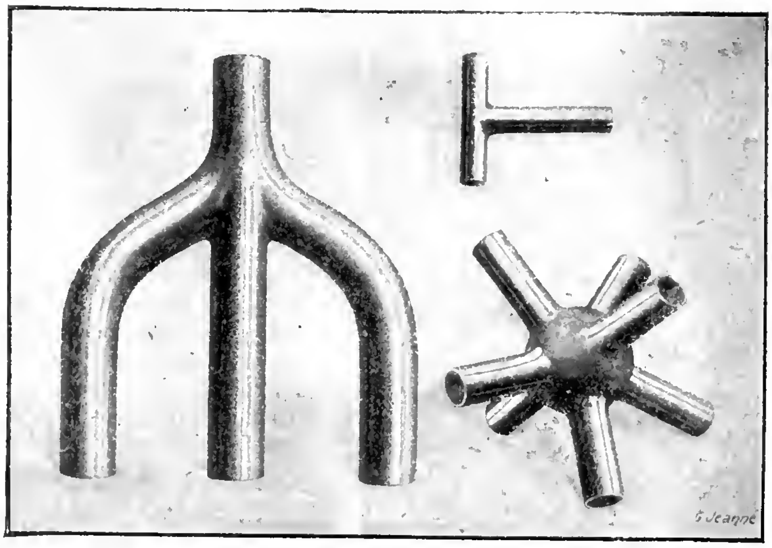
The use of combustible gases to generate heat in such a manner that it can be applied locally with a blow pipe or torch is the distinguishing feature of autogenous welding. The remarks which follow are based on the use of acetylene gas, combined with oxygen.

PRESS FRAME REPAIRED.

Oxy-acetylene welding is the art of so applying the heat of combustion to the work that a welding temperature is quickly obtained and maintained until the material is in a state of fusion, which then permits the union of surfaces or parts, the building up of areas, filling of cavities or hollows, the removal of metal, and cutting apart of various shaped bodies. Steel plates up to $1\frac{1}{2}$ inches in thickness and round or square bars up to 6 inches in diameter can be welded with the blow pipe without alteration to the chemical or physical characteristics of the material.

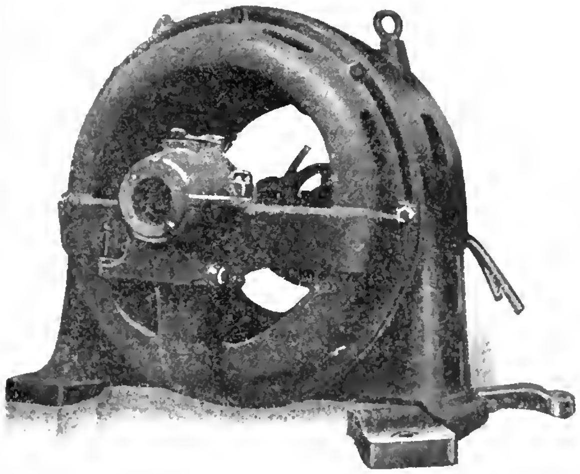
Oxy-Acetylene Equipment

The necessary equipment consists of a



BUILT UP COPPER PIPES

blow pipe with various size nozzles or burners, and a supply of oxygen and acetylene, the two gases being most conveniently handled when contained in steel tanks or cylinders.



BROKEN FOOT OF ELECTRIC MOTOR.

Compressed oxygen is readily obtainable in most industrial centres, while tanks containing dissolved acetylene are familiar to every automobile user. These tanks contain a porous substance saturated with acetone, which is a liquid possessing the power of dissolving or absorbing acetylene gas when supplied under pressure. As a result of this a greater quantity of gas can be stored at a less pressure, and in smaller space than when compressed alone. Generators are also used in which the acetylene gas is formed by the action of water on calcium carbide. They are desirable in large permanent installations, but for general work, the portable plant has many advantages.

Repair Work

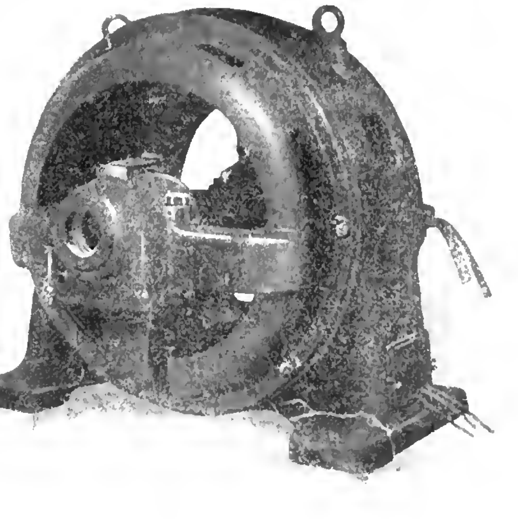
The most widely known field for welding is in repair work. In many cases repairs may be made in a few hours on parts, the replacement of which would require days and sometimes weeks. The indirect saving due to the none-stoppage of plants is frequently even more than the direct savings due to repairing instead of replacing.

Consideration must be given to all these features before deciding that a job can be profitably performed by welding. When heavy sections have to be operated on, the cost increases rapidly, while the effects of expansion and contraction have to be fully considered, carefully observed, and guarded against by various methods and devices.

Cast Iron

With suitable equipment and materials, a capable operator can weld cast iron parts, the joints between which will have a strength of more than 100 per cent. of the original material. This is due to the use of feed rods of better quality material than the work. In order to avoid hardness in the welds it is necessary to use feed rods rich in silicon, i.e., about 5 per cent., and take all precautions against too rapid cooling.

Cast iron, having no elongation, is not suited to withstand stresses produced by unequal heating, and in most cases it is necessary to preheat part or all of the work to be done. Even preheating does not always overcome this trouble with cast iron and much experience on the part of the

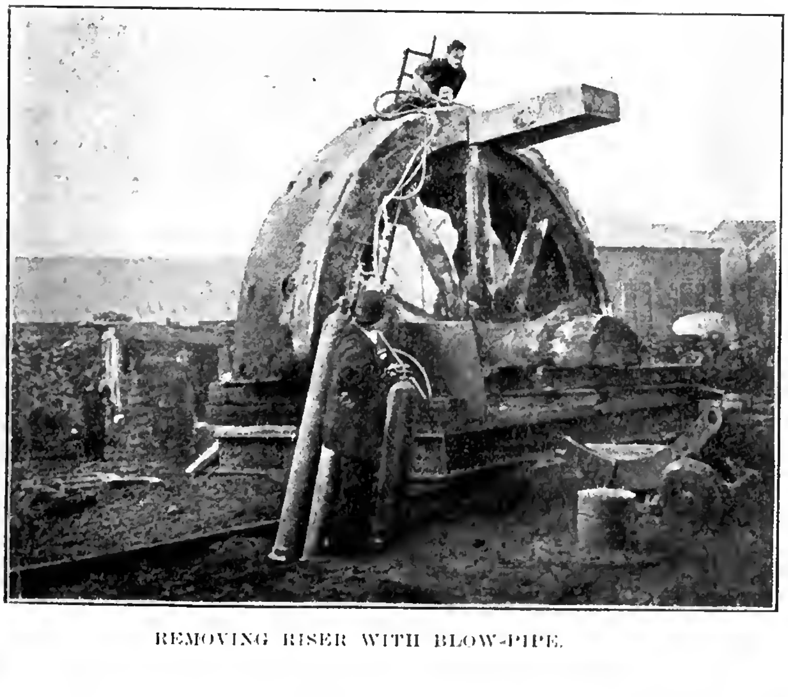


MOTOR WITH WELDED FOOT.

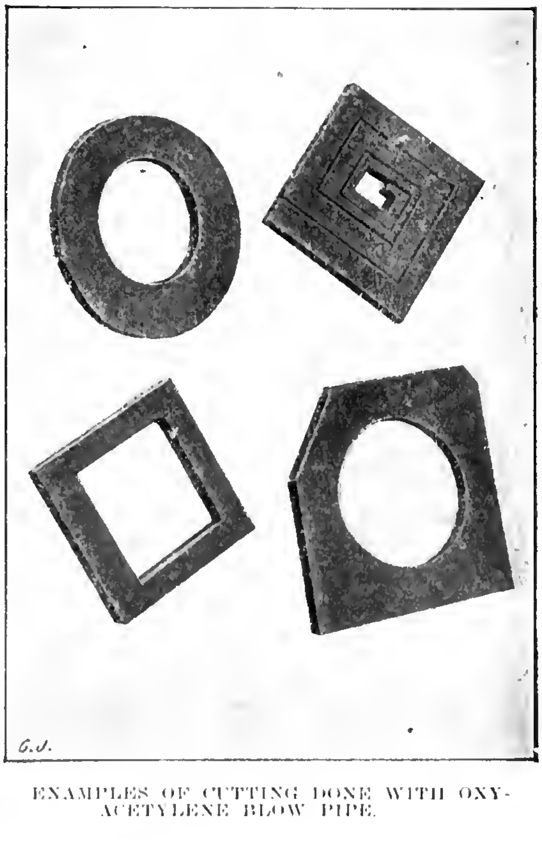
operator is required to insure the production of good work.

Steel

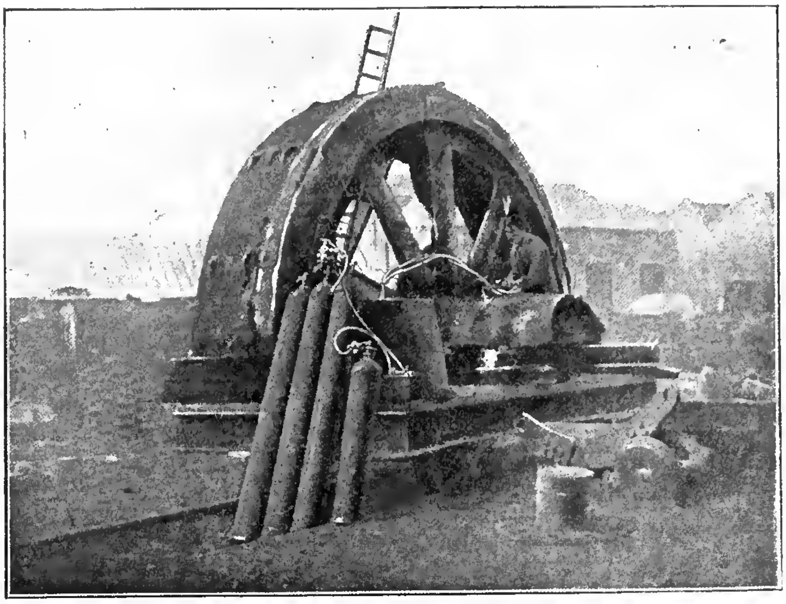
A proper weld in steel or wrought iron should always show above 85 per cent. of the original strength. The mere fact that an operator fuses a piece of feed rod and allows the drops to fall on comparatively cool metal does not constitute welding. It is only adhesion. A careful welder will have all surfaces at the required temperature, he will avoid the formation of oxide by controlling the



REMOVING RISER WITH BLOW-PIPE.



EXAMPLES OF CUTTING DONE WITH OXY-ACETYLENE BLOW PIPE.



CUTTING OFF HEAVY RISER.

flame, by the proper use of the hammer at the right moment he will improve the grain of the metal, and by further use of the blow-pipe, he can so anneal the work that the efficiency of the joint may be as high at 95 per cent.

In addition to cast iron and steel, oxy-acetylene welding is largely used for welding brass, bronze, copper, aluminum, and other metals. Its use in cutting up structural work such as bridges and buildings in course of demolition is a very great saving of time over the old laborious hand cutting. After heating a suitable spot on the plate or beam to melting point, the acetylene gas is turned off, and a stream of pure oxygen is played on the heated metal causing it to melt and at the same time generate enough heat to allow the action of the oxygen to be continued along the desired line until the piece is cut through.

The removal of risers and feeders in foundry work is an everyday application of the process.

Manufacturing Applications

The application of autogenous welding to the making of steel barrels, tanks, etc., has been carried out with considerable success, but a large field of usefulness has so far only been touched. For articles made of plate up to 3/8 inch thick it is very suitable, making a perfectly tight joint which requires no caulking, is cheaper than riveting, and presents a better appearance.

In the manufacture of steel and iron pipes, flat strips are rolled to shape and welded by an automatic machine. This process is used in making water and gas pipes, bicycle tubing and bedsteads.

By means of oxy-acetylene welding, water, steam and gas pipes have been reduced in thickness as threaded joints are eliminated. Many installations of complete systems have been made without a screwed joint, the joints being welded while in position. Very few fittings are required, as a hole can be cut in a pipe and a branch welded on. The welding of flanges to pipe is also another great advantage.

The construction of heating boilers by welding together parts made of steel plates, has been greatly developed also the construction of radiators by the same method. Other applications which can be made include the following:—

The construction of steel cars, doors, frames, window sashes, etc.

Poppet valves for internal combustion engines.

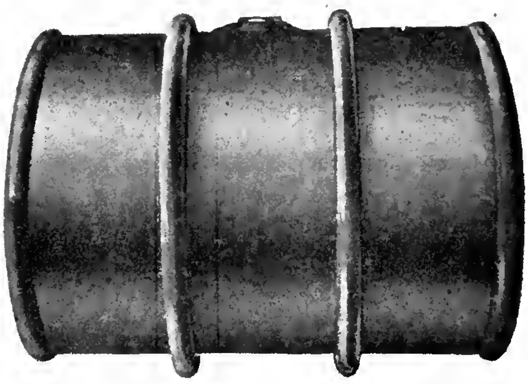
Cement pipe lines where the liners are shells of light gauge steel.

CUSTOMS RETURNS HIGHER

AN increase of over two millions in Customs receipts is the healthy condition shown by the figures issued for September by the Department of Customs.

For the month, receipts totalled $8,029,665, as compared with $5,919,273 in September of last year, or an increase of $2,110,391. For the six months, ending September 30, of the present fiscal year, receipts have been $44,760,830, as compared with $43,044,913, an increase of $1,715,917.

This indicates that for the first half of the 1915 financial year, at least, the Customs revenues have been swelled by the tariff increases of last season to the extent of almost two millions. As it usually takes some time before Customs taxes have their due effect, the showing for the last half of the year is expected to be even better. It must be remembered in comparing the first six months of this year with those of 1914 that the latter period includes but two months of war.



WELDED STEEL BARREL.

The pressure in the chamber of a gun at the moment of discharge of the shell is about 25 tons per sq. in.

MOLDING A LARGE ACCUMULATOR BASE

By J. H. R.

THE St. Lawrence Iron Foundry Co., of Montreal, Que., who make a specialty of supplying all kinds of iron castings to the trade are at the present time remodelling a portion of their plant and equipping same for the machining of 4.5 high explosive shells. They will, however, continue to develop the foundry end of their business, and in order to give your readers an idea of the nature and scope of same, the molding features connected with the production of a large accumulator base casting are here detailed and illustrated.

This casting, which will weigh in the neighborhood of 17,000 lbs., is for the base of one of the largest accumulators yet built in Canada, and which is being constructed for the Montreal Ammunition Co., by the Canadian Boomer & Boschert Press Co., of Montreal. The accumulator, when completed will furnish a pressure of 1,500 pounds per sq. inch to hydraulic presses engaged in the drawing of shell cartridge cases. The casting will consist of 25 per cent. steel, which is obtained from the use of the discarded shells and shell ends from shell making plants. The pattern for this base casting was of the skeleton type, being quite satisfactory in view of the fact that only one casting would be required.

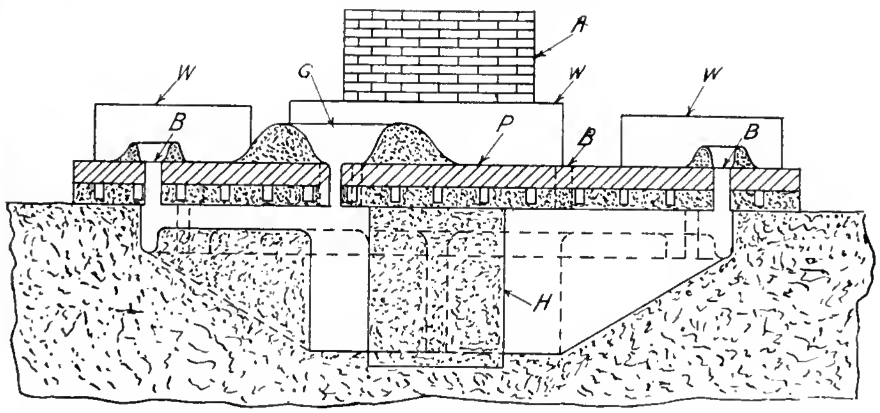

FIG. 1. SECTION THROUGH GREEN SAND MOLD FOR ACCUMULATOR BASE.

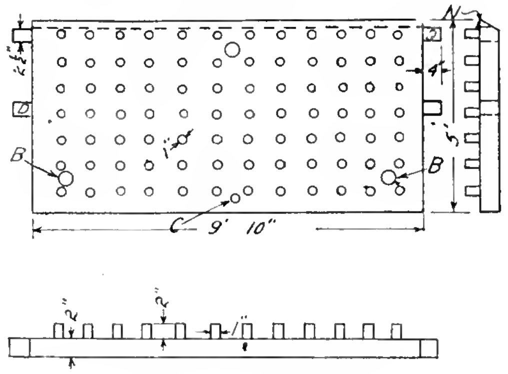

FIG. 3. COPE PLATES.

Preparing the Mould

The mould was prepared as shown in Fig. 1. A pit was dug in the floor and the pattern set into it, and levelled up. Green sand was shoveled in and thoroughly rammed, care being taken to have the sand of uniform density at all points. As there was no base to the pattern the openings between the ribs made it easy of access.

When the spaces between the ribs were completely rammed, the surplus sand was removed by sweeping the surface above the ribs leaving the space for the metal at the base of the casting. The sand having been levelled off, the pattern was carefully removed, the moulder and his helper afterwards cleaning up and smooth facing the various surfaces. A view of the mould at this stage is seen in Fig. 2. As it was not thought advisable to construct a special cope the method shown in the figure was adopted as this had proved satisfactory in former cases.

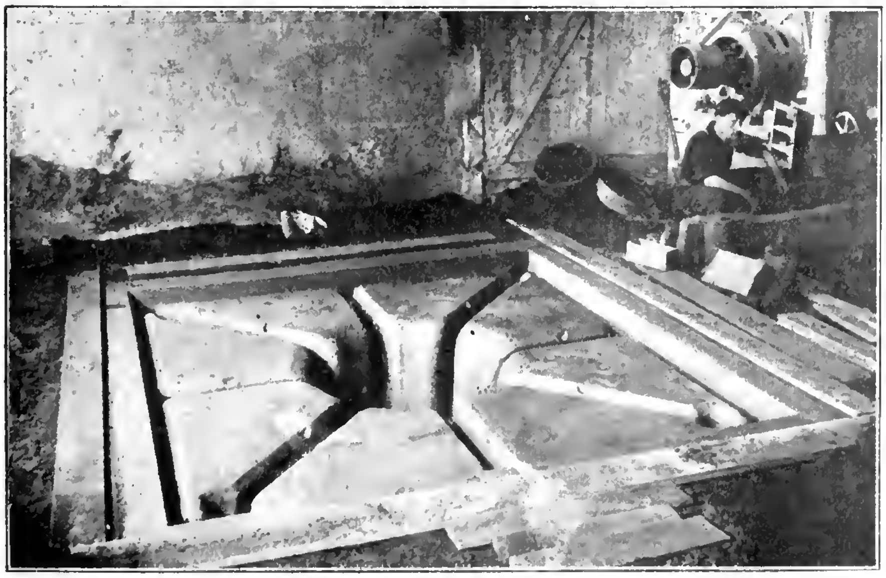

FIG. 2. COMPLETED GREEN SAND MOLD FOR ACCUMULATOR BASE.

Special Cope Plates

Two plates of cast iron weighing about 2 tons each and similar to that shown in Fig. 3 were cast. Pins A which protruded about two inches from

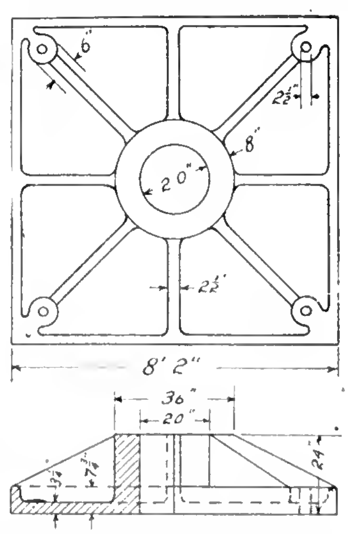

FIG. 4. ACCUMULATOR BASE.

the main plate and were about one inch in diameter were placed irregularly about the surface for the purpose of retaining a layer of sand spread over the surface and which was rammed up and surface levelled by placing the plate in the framework shown to the right is Fig. 6. This thickness of sand amounted to about $2\frac{1}{2}$ inches. Cored holes B were put into the plate so as to come directly over the corners of the casting and be just outside of the boss as shown in Fig. 4, which is a sketch of the finished casting. The holes C were for inserting eye-bolts for convenience in handling, while the lugs D, were used for turning the plate over when the sand facing was in place.

Arrangement of Mould

The arrangement of the mould for producing these plates, two of them being used, is shown in Fig. 5. A space sufficiently large was cleared on the floor and the sand rammed to an even density. A skeleton frame was used to make the required plate dimensions which were about two inches thick by nine feet ten inch by five feet. When placed over the mould as shown in Fig. 1 there was a bearing of 10 inches all around the edge.

The object of making two plates in place of one was for convenience in handling. It will be noticed that the plate edges which come together in the centre of the mould as shown at N are bevelled. This is for the purpose of securing a good close joint with little labor. When the plates are butted, the trough formed by the two bevels is rammade with a little waste and sand thus securing a close joint and avoiding fins or burrs, which would be liable to appear if the plates were left the full thickness at their edges.

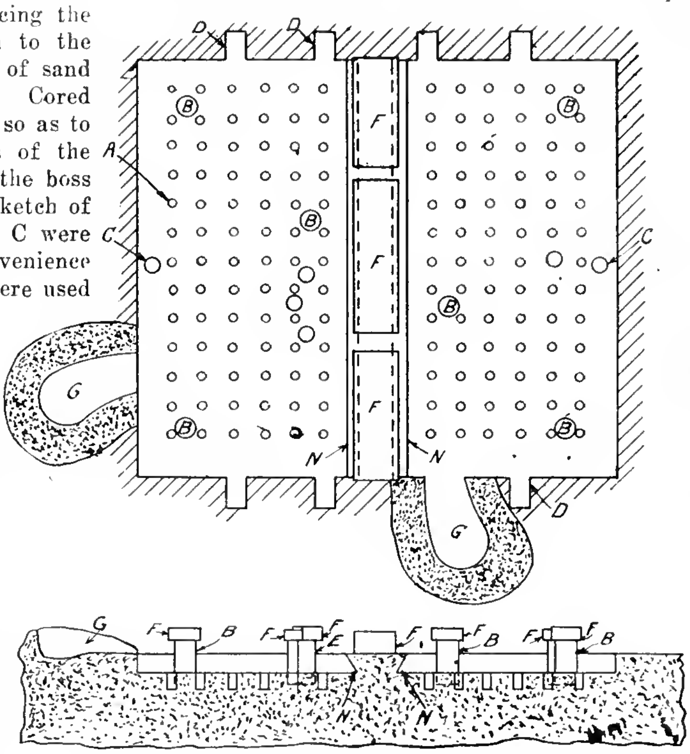

FIG. 5. GREEN SAND MOLD FOR COPE PLATES.

The layout of this mould is shown in Fig. 5. The cores B are for the risers while those at E were for the runners from the pouring basin when placed over the mould Fig. 1. The pouring basins G were placed to one side of the moulds. The cores were prevented from shifting by means of the weights F. A view of the mould in readiness for pouring is shown in Fig. 6.

Accumulator Base Casting Mould

A sketch of the mould for the accumulator base casting is seen in Fig. 1. After the mould is prepared as per Fig. 2, the plates with their facing of sand are placed in position and the basins for pouring and risers arranged. The weights W, together with that of the plates, amounted to about ten tons. The plates at the centre rested on the 20-inch cove H, which extended up level with the base of the cutting.

Pouring

The largest ladle in the shop which was handled by a 5-ton "Whiting" crane had a capacity of only 5 tons. It was, therefore, necessary to provide some means of continuous pouring. The brick bosh A shown at the rear of Fig. 1 was constructed of sufficient size to hold about 4 tons of iron and this was filled with molten iron while the 5-ton ladle

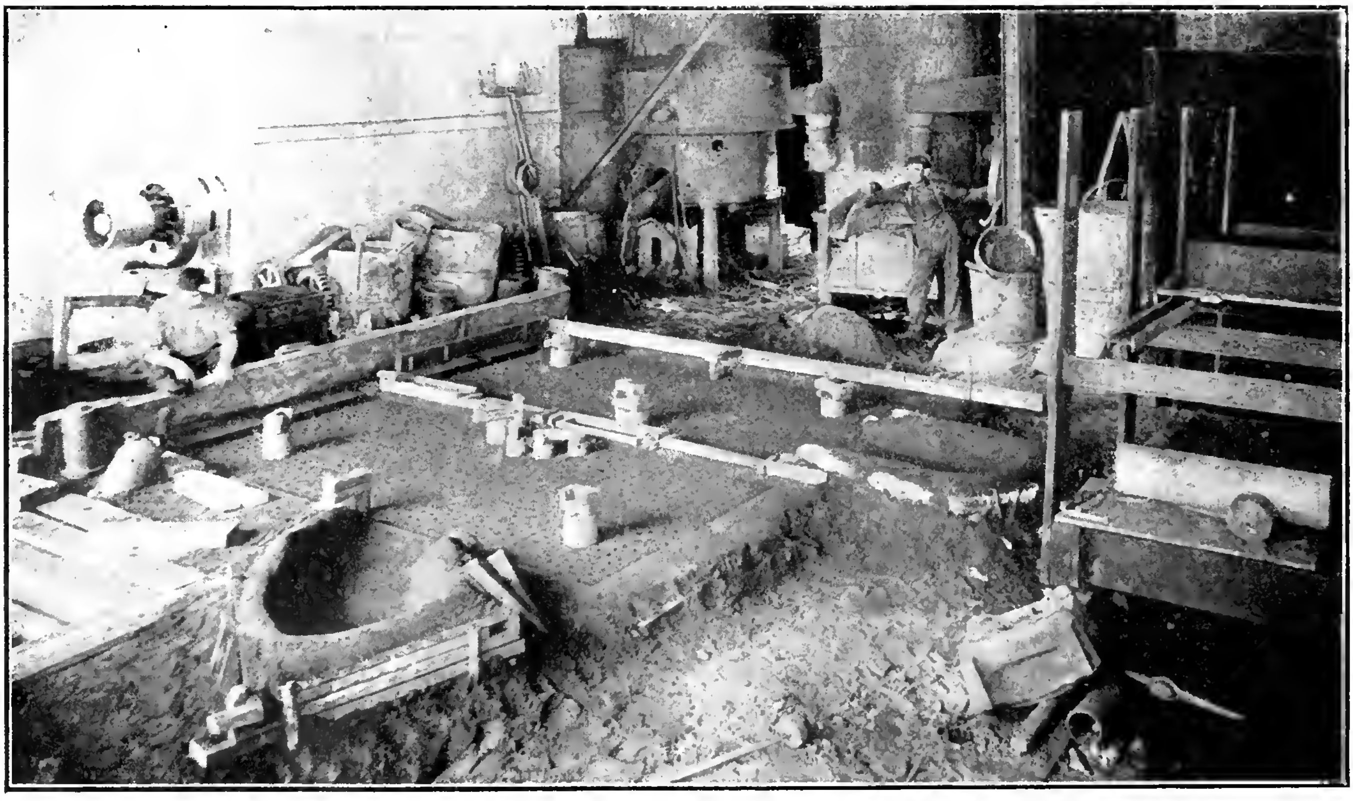

FIG. 6. GREEN SAND MOLD FOR COPE PLATES IN READINESS FOR POURING.

was being poured. When the 5-ton ladle was emptied, the bosh was tapped, and while the metal was running in the ladle was being refilled.

One of the problems which confronted the foundry foreman was the removal of the casting after cooling, as the 5-ton crane was not deemed capable of lifting a casting which was expected to weigh between 8 and 9 tons. One side was raised at a time by which process it was gradually turned over on to a track prepared with special rollers. It was then removed to the Canadian Boomer & Boschert Co. shops across the road in which the accumulator was to be erected and completed.

CONCERNING BELT SLIPPAGE

By N. G. Near.

ANSWERING R. McLaren, who says he is "still unconvinced that a slipping belt necessarily means fuel waste," I do not know how I could explain the matter more simply than by use of the hoisting engine.

This is the principle upon which all Prony brakes are made, and this principle is used in running all "Prony" brake tests. Therefore, when the slip of a belt becomes 100 per cent., the belt will not move the driven pulley at all and the whole arrangement becomes a veritable "Prony" brake.

With reference to the hoisting engine, Mr. McLaren says:

"We will assume that the weight is suspended from the drum by a cable and that the cable slips on the drum, the tension being adjustable in a manner similar to the brake band. We will assume also that the drum has a radius of 1 ft. and that it turns at the rate of 100 r.p.m. The power required to hold the weight stationary would be $(2 \times 1 \times 3.1416 \times 100) \div 33000 = 628.32$ h.p. How then would he cause the weight to rise?"

It is a fact that the weight of 33,000 pounds cannot be raised without some additional power because nothing can be set in motion from rest without the exertion of some force acting through distance. An additional hundredth, thousandth or millionth of a horse power will therefore be sufficient to raise the weight. To raise it "quickly" though, may require an additional 25 or 50 h.p., and this can easily be computed from the familiar formula, $F = Ma$, where F = force, M = mass, a = acceleration given to the 33,000 pound weight.

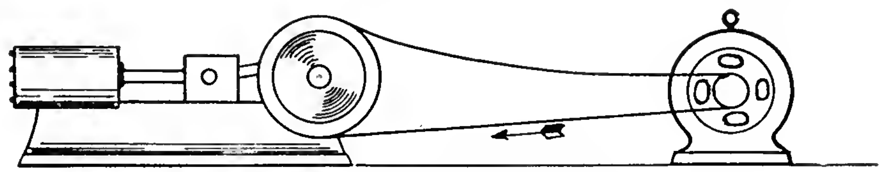
It is, therefore, evident that should the engineer so choose, and should he happen to have that amount of energy available, he could expend an additional 1,000 h.p. or more in raising the weight.

It is true, as Mr. McLaren says, that running the engine faster or increasing the tension in the cables, will accomplish the desired end, and either operation will require more steam.

No, I would hardly claim that it is easier to climb a stair than to walk along a level floor. When you climb a stair you store potential energy within yourself, and it requires work to do that, but when you walk along a level floor, the summation of all the work done by one's self on one's self is zero. No work is done at all.

The Gas Engine Example

As for the gas engine, let me explain in detail why each per cent. of belt slip on gas or gasoline engines represents a fuel loss of more than one per cent. I refer here only to gasoline engines that fluctuate violently.



CONCERNING BLLT SLIPPAGE.
When running, belt slip zero; tension in upper half belt, zero; tension in lower half belt, 1,000 pounds.

The tension in the belt here is 1,000 pounds only because the load does not require a greater tension. Should the load be greater, the tension would of itself become more than 1,000 pounds, and there would be no slip, but, there is a limit. Let us suppose that the belt slips at 1,100 pounds. This tension is reached when the engine "jerks," due to the sudden explosions, and, during the instant of slip, the tension of 1,100 pounds is doubtless maintained. More energy is being taken from the engine, then, during the instant of slip than during an instant of normal pulling, and I therefore naturally conclude that the full consumption is greater, due to slip, than if there were no slip.

The best way to eliminate this loss is to make the fly-wheels so heavy that the fluctuations will not be violent enough to cause belt slip, or, the explosions may be made frequent enough to produce the same effect.

I trust I have now made myself perfectly clear.

POINTS ON RUBBER BELT CONSTRUCTION

BRIEFLY, the process of belt manufacture is as follows:—Cotton duck, of such weight and strength as is required for the work to be done, is frictioned or coated with rubber upon the calender. The quality of the rubber, like the weight and strength of the cotton, varies according to the nature of work to be done. The frictioned fabric is then cut into definite widths, according to the width of the finished belt, after which the plies of fabric are built up either by folding or laying ply upon ply or a combination of both.

After the belt is built up and the cover applied, a seaming strip of high-grade rubber is laid over the outside joint in order to weld this joint firmly together and prevent separation or opening up of the seam. The raw belt is then rolled upon a shell and given a slight cure in open heat in order to vulcanize the edges. After the "first cure" the belt is carefully vulcanized between the polished plates of a powerful hydraulic press. The rubber is forced into the duck, and the whole belt becomes perfectly smooth and firm. Just prior to vulcanizing, the belt is stretched under great pressure, thus minimizing stretch when the belt is put in actual use.

Rubber belts should be run at not less than 200 ft., nor over 5,000 ft. a minute, a good average being 2,000 ft. Shifters should not be used, as, once the edges of rubber belting are worn through, the plies readily separate. All animal oils and greases are injurious to rubber belting.—Practical Engineer.

BRITISH EXPORTS TO CANADA DECREASE

THE following are the official figures from London, of trade between Canada and Great Britain in the undermentioned articles during August:—

Imports From Canada

	Aug. 1915	Aug. 1914
Wheat	£282,380	£1,506,011
Wheatmeal and flour	238,132	147,889
Barley	78,984	85,797
Oats	29,481	97,395
Bacon	278,791	129,404
Hams	49,392	21,380
Cheese	700,012	723,930
Canned Salmon	115,392	2,948
Canned lobsters	28,964	53,622

Exports to Canada

Spirits	£ 29,959	£ 54,359
Wool	15,650	16,767
Pig iron	665	869
Wire	983	2,948
Galvanized sheets	5,118	18,241
Tinned plates	2,099	5,403
Steel bars	4,494	7,134
Pig lead	849	4,050
Cutlery	5,429	6,037
Hardware	2,370	10,596

PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

SHELL MACHINERY IN FRANCE

THE fact that the French nation is mobilized to a man for the purpose of producing shells as well as actual fighting is of particular interest to our readers at the present moment. Our allies were alive to the necessity for extraordinary shell production long before it was realised by ourselves, and the efficient manner in which munitions manufacture was tackled and made a national problem has already earned the admiration of not a few British engineers.

Previous to the outbreak of hostilities, the firm of Alfred Herbert, Ltd., of Coventry, Eng., enjoyed a widespread business with various European nations, but since then, their activities have been limited to certain countries. One of their travelling operators in France has done excellent work in the designing of shell machinery which has been made by the firm's customers in France. His description of conditions and methods which we reproduce are from the house organ of Alfred Herbert Ltd.

In the first place the various works in the country were grouped, the shops in each group working in conjunction with each other, while an expert engineer was put in control of the group.

Contracts were then given out to the controller of each group, who divided and sub-divided the work amongst the establishments under his control, according to the capacity of each shop. Machine tools changed hands according to the work given out; for instance, a particular shop had a few automatic machines, but not enough to undertake a large contract for shell bodies. These automatics were thereupon transferred to another shop which had more of the same type, while the latter sent some of its smaller machines to the first.

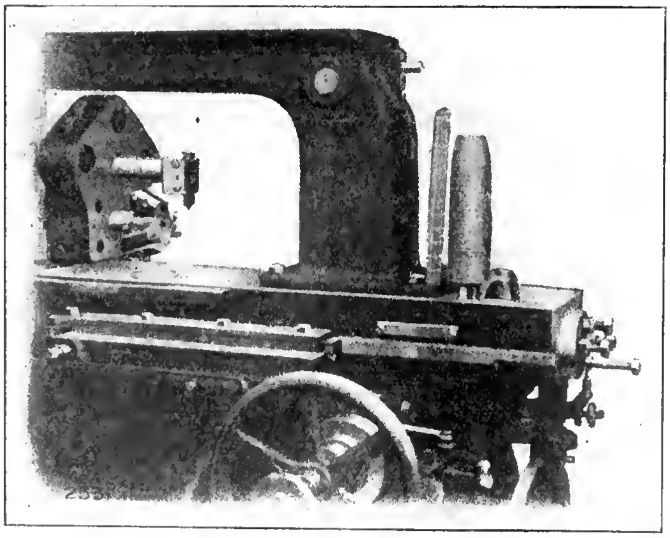


FIG. 1. 75 MM. H. E. SHELL, WITH SECTION CUT FROM NOSE.

With a large number of automatic machines, the second shop could turn out a large number of shell bodies in an efficient manner, while the first shop was put into better shape for handling fuses and grenades.

At the same time, it was no easy matter to switch all these works over from building motor cars, locomotives, etc., to shell and gun production. Tools were a great problem, but it was not allowed to remain a problem long. One or more works in each group was told off to act as a sort of tool room to the rest, a plan that has worked very satisfactorily.

Automatic machines are not being used for turning and boring shell bodies to any great extent in this country, but our French allies have turned to account any and every machine they could lay their hands on.

Although we are not allowed to mention names, it is by the courtesy of the controller of one of the aforementioned groups, that we are permitted to publish the accompanying illustrations with particulars of the tools used for producing 75 mm high explosive shells on our Nos. 4 and 6 Automatic Turning Machines.

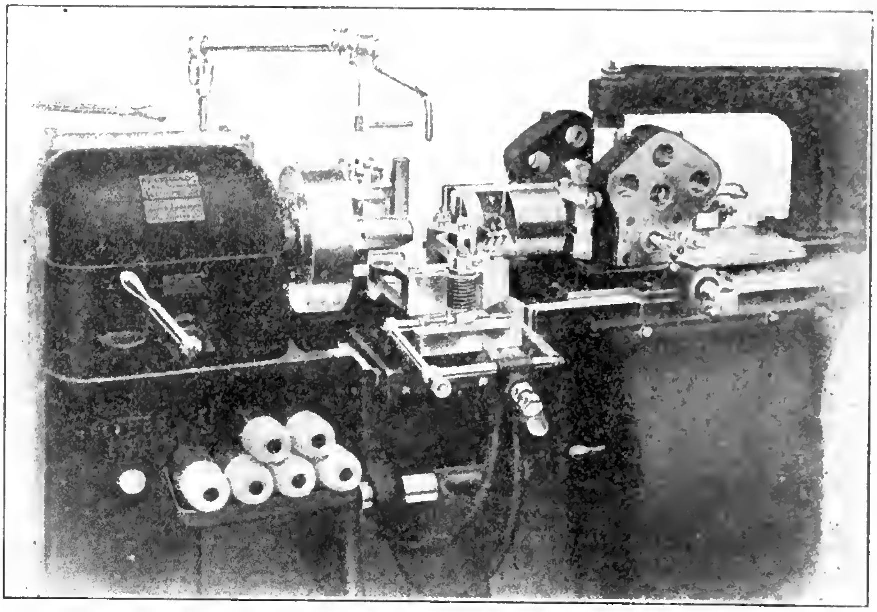

FIG. 2. ROUGHING BOX TOOL AND PROFILER.

The French 75 mm high explosive shells are made from forgings. These are first rough turned and finish bored previous to a closing-in operation. After the nose has been closed-in the shell bodies are delivered to the Automatic Turning Machines for the finishing operations. It should be noted that during the first rough-turning operation, the boss at the closed end of the shell is turned to a definite size with limits either way of 0.008 inches.

This boss is made use of after the closing-in operation, for holding the shell body true in the chuck.

In the first operation on the Automatic, the shell body is held in soft jaws, mouth outwards, while a special draw-in chuck fitted in the spindle, grips and holds true the boss on the end of the shell.

The shells are located by the bottom of the hole, using a device that gives a definite length from this point to the front of the chuck jaws.

The box-tool shown in position in Fig. 2 first turns the shell body to about half way down. The special radius tool

fixed to the front cross-slide is then fed forward by the roller device seen on the next turret face. At the same time the mouth is reamed. This operation is seen in Fig. 3.

This illustration also shows the special recessing tool used for boring and dovetailing the mouth. Owing to the necessity for fitting the profiling tool to the front cross-slide, this recessing tool has to be fed by the rear cross-slide. It was, however, found necessary to have the tool inverted so that the spring and lever feed reversing mechanism seen in the illustration, Fig. 3, was adopted, and works very well.

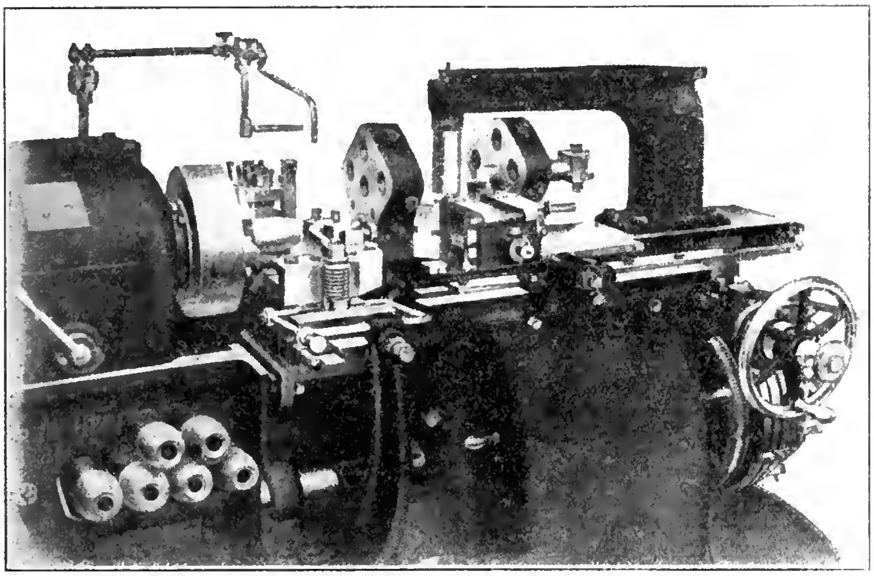

FIG. 3. PROFILING TOOL IN OPERATION.

In the second operation the rear portion of the shell is finished. Owing to the manner in which the lengthwise limits of the shell are specified, it was found impracticable to locate the shell by the mouth; the best way and the one adopted is to fit a bush in the machine spindle, boring this out to suit the profile of the shell nose. The shell is then pushed into this bush and gripped by soft jaws in the chuck. Centring and locating the shell in this manner by the finish-turned nose effectually prevents the shell from running out of truth.

The outside diameter is first finish turned with tools in the turret. The band groove is cut by a tool in the rear cross-slide and the outside of the shell between the band groove and the closed end is then turned taper by means of the profiling slide seen in Fig. 4, and a taper former carried in the front cross-slide.

The special knurling apparatus, seen in Figs. 4 and 5, is then used for serrating the bottom of the band groove.

The total time for both operations, including chucking and removing, is 17 minutes, the speed at which the shells are turned being approximately 66 feet per minute.

The roughing tools used last for about 30 shells, while the finishing cutters will machine 60 or more before they require re-grinding.

Re-setting the tools after sharpening takes 10 minutes for the roughers and 15 minutes for the finishers. This gives a total output of about 38 shells per day of eleven hours per machine.

Automatic Turning Machines are also being employed on the first operation on 105 mm shells in a similar manner to that described for the first operation on 75 mm shells.

For profiling the nose however, it is necessary to take two cuts, roughing and finishing. These two cuts take place simultaneously, a double slide arrangement being mounted on the turret, the two slides being guided by formers held in the front and rear cross-slides.

Although there is about half an inch of metal to remove near the nose end of the shell, this operation is completed in 20 minutes.

GLASSES FOR EYE PROTECTION

DEMANDS for adequate eye protection are becoming more insistent with the widespread use of apparatus for such processes as oxy-acetylene welding, electric furnaces of various types, and all metal manufacturing processes which involve the exposure of operators to direct heat and light rays of considerable intensity. In a report on investigations regarding the provision of suitable glasses for eye protection, in a recent issue of the Iron Trade Review, M. Luckiest, of the National Lamp Works, presents a number of interesting facts relative to light and its control.

The energy which is radiated from all hot bodies into the surrounding media is sent forth impulses or waves. In a manner similar to that of a wireless receiving station, the eye is physically capable of perceiving pulses or waves of a certain definite frequency or length, name from 0.39 micron to 0.75 micron, a micron being a small unit of measurement equivalent to one one-thousandth

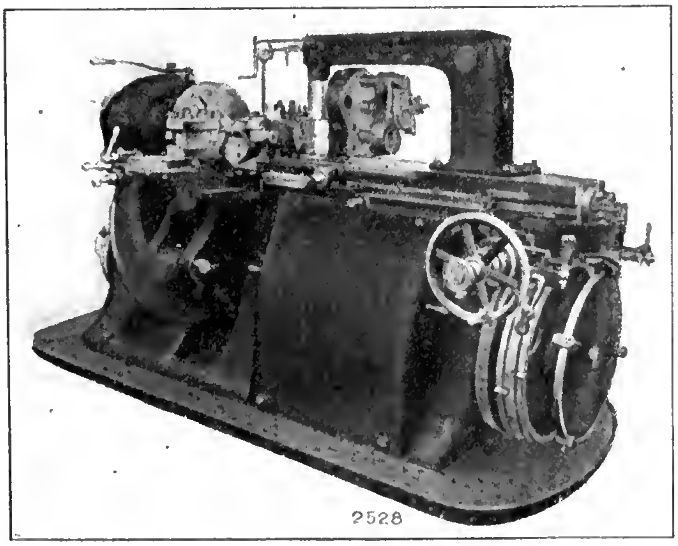

FIG. 4. TAPER TURNING AND KNURLING.

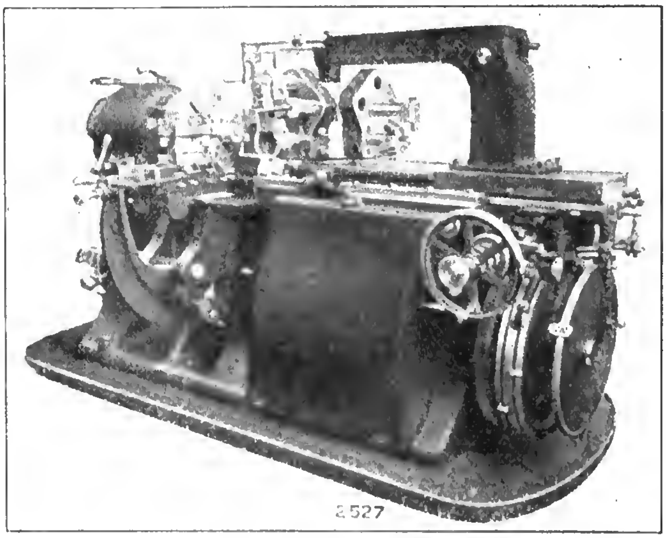

FIG. 5. SHOWING KNURLING AND ROUGHING TOOLS.

of a millimeter. These limits constitute what is known as the region of visible spectrum.

Various Kinds of Rays

A hot body before it has reached a sufficiently high temperature to become luminous, gives off only what are commonly known as "heat" rays. As a matter of actual fact, all rays, whether visible or invisible, when absorbed by a medium, produce heat in that medium. As the temperature is increased, visible rays begin to emanate from the heated body. Further increases in temperature cause ultra-violet or chemical rays to emanate, the relative amount of the various kinds of rays emitted depending not only on the temperature of the body, but also on the substance of which it is composed.

The ultra-violet rays, that is those of shorter wave length than 0.39 micron, have no illuminating power. Certain varieties of them however are very active in destroying animal tissue. Complete data regarding them has not been obtained, but their harmful properties render it desirable to prevent any of these rays from entering the eye.

The retina or nerve surface of the eye can also be damaged by focussing excessive amounts of energy upon it. The selection of suitable glasses therefore involves two important features besides the provision of mechanical strength, viz. ultra-violet rays should be prevented from falling upon the eye, and the intrinsic brightness of the image thrown into the eye should be reduced to safe limits.

Very few glasses totally absorb the ulta-violet rays, and these are objectionable owing to the strong coloring in them. Yellow-green is the most desirable color.

Heat rays should be prevented from entering the eye because it is suspected that eye fatigue arises from the absorption of excessive heat. A desirable feature of the yellow-green glass is the fact that variations of brightness due to the changes in temperature of incandescent bodies have the same relative appearance to the eye when using this glass, as when using uncolored glass. This fact accounts for the satisfaction experienced by welders when judging temperatures through these glasses.

Common smoke glasses simply reduce the amount of light, but do not absorb the unsafe ultra-violet rays. A variety of glass known as Akopos has been found which absorbs all of these rays, and can be combined with other glasses which are necessary to reduce undue brightness.

The appended table gives designations of safe glasses for various metallurgical processes.

Process.	Temperature degrees Fahr.	Safe glasses.
Electric arc	6,200	Ak.+E.S.
Electric arc under pressure	6,450	Ak.+E.S.
Oxy-hydrogen flame	3,600	Ak.+S.16
Oxy-acetylene flame.	4,350	Ak.+S.20

Ak. is an abbreviation for Akopos: E.S. S 16, etc., are opticians' designations for glasses of various shades.

TAPER FUSE THREADS

FUSE adapter bushes of naval lyddite shells have a taper hole in them cut 14.083 threads per inch. In the 6-in. shell, the length of this thread is about 2 in., and it is quite impossible to get anything like a satisfactory job on so long a thread by using taps, as each of the cutting edges on the tap leaves a line where it stops cutting, and there is a danger of breaking the tap by running in too far.

For handling fuse adapter bushes on "Herbert" No. 4 capstan lathes, taper turning and chasing attachments, Fig. 1, are employed for cutting the thread. Previous to being chased, the hole is finished with taper reamers. The chasing attachment is shown in position in the illustration.

In action, the lathe spindle is run reversed and the chaser travels out from the work, operating in conjunction with the quick withdraw motion of the patent chasing saddle. The actual thread cutting is very rapid, taking approximately 40 seconds for a thread of 2 in. long, whilst the finish and accuracy obtained is excellent.

The corresponding male portion is screwed with a 1¼-in. "Coventry" patent self-opening diehead, fitted with the taper threading attachment shown in Fig. 2. The taper is governed by a former bar, which is forced outwards by a spring, and kept stationary by a stop held in the tool post of the lathe, while the diehead travels forward.

The advantage of cutting taper threads by this method is that the work is finished quite smooth and round, without the four ridges left by taper dies where they cease cutting.—Herbert's Monthly.

As men improve in the service they render, their incomes should improve; they should be paid in proportion to the ability they show in the development of the business, whether it is an improvement in quantity or quality or both.

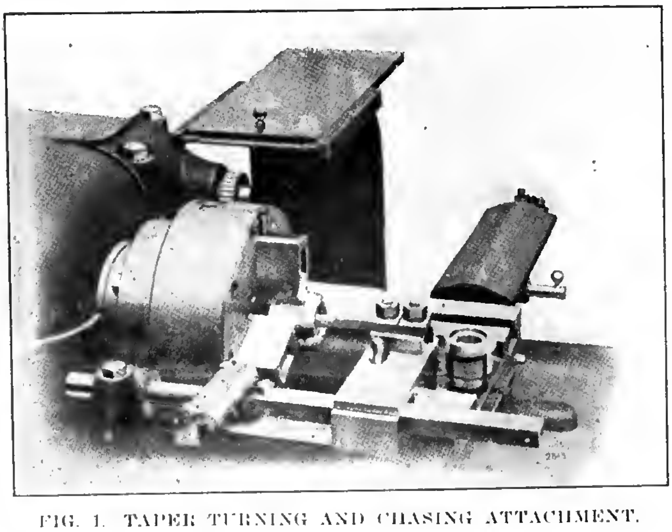

FIG. 1. TAPER TURNING AND CHASING ATTACHMENT.

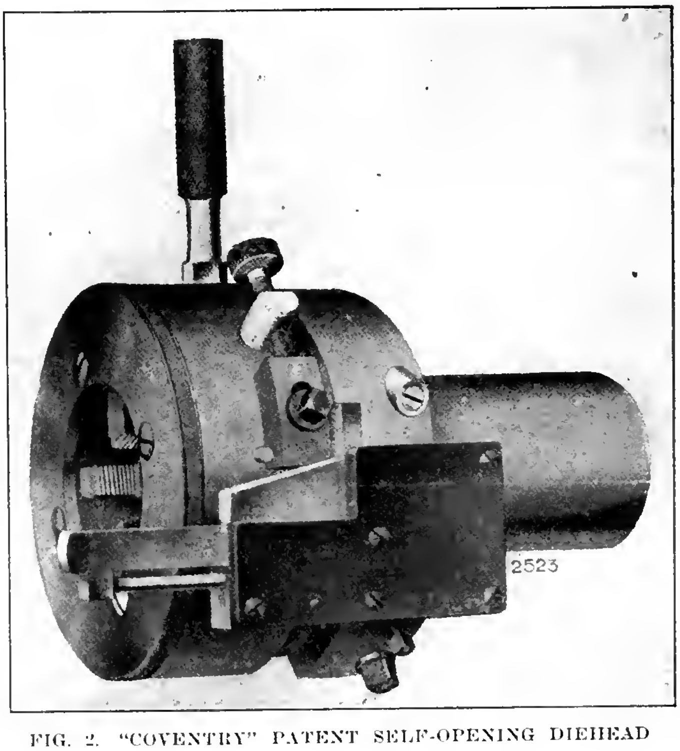

FIG. 2. "COVENTRY" PATENT SELF-OPENING DIEHEAD

SCIENCE OR COMMON-SENSE?

THE beginning of the winter session of studies in the many technical schools throughout the country brings into increasing prominence every year, the subject of technical education. It is not very many years since discussions centered on the question, rather than the subject of technical education. People, especially employers, looked askance at the benefits which the rising generation of workers were supposed to be deriving from those institutions, and the practical value of the training, to the employer at any rate, was assessed at what, to the student, was a discouragingly low value.

The recent opening of the new Toronto Central Technical School marks what may well be regarded as a climax in the development of technical education. Quite apart from the magnificence and completeness of the institute as an educational plant, the significance of the event, as marking a further advance toward ultimate national efficiency, should make a deep and lasting impression on those manufacturers whose future prosperity and welfare will be largely dependent on the efficiency of the employees of the next generation.

By a peculiar coincidence, the recent meeting of the British Association for the Advancement of Science took place at Manchester almost simultaneously with the opening of the school in Toronto. As representing what might be turned the extremes of scientific knowledge the two events offer one of those contrasts which are characteristic of an age of advancement.

Knowledge feeds upon itself, and will not be suppressed. Ambition is the fruit of knowledge and a nation with no ambition is destined to ultimately sink into oblivion. Unguided ambition becomes recklessness, and when indulged in on a national scale induces catastrophe.

Professor Arthur Schuster, F.R.S., delivered his presidential address to the British Association on the subject of "The Common Aims of Science and Humanity." Although a man of German extraction, his deservedness of such a high honor was fully recognized by the authorities, and the subject matter of his address discloses a mind bereft of all traces of "kultur" and possessed of that receptive, analytical and constructive ability which is truly characteristic of the British scientist.

If it were possible to speak individually to the many thousands of young minds who at the present moment are digging into the rudiments of science with all the enthusiasm born of youth and novelty, advice for each one could be found in Dr. Schuster's Address.

In discussing the question of scientific success, he quotes a previous president who used these words regarding the qualifications necessary to make a man a great scientist: "But, I hear someone say, these qualities are not the particular attributes of the man of science, they may be recognized as belonging to almost everyone who has commanded or deserved success, whatever may have been his walk in life. That is so. That is exactly what I would desire to insist, that the men of science have no peculiar virtues, no special powers. They are ordinary men, their characters are common, even commonplace. Science, as Huxley said, is organized common-sense, and men of science are common men drilled in the ways of common-sense."

The student who wishes to attain success and all the happiness that accompanies the attainment of objects sought, will find his path smoothed, his interest sustained, and his accomplishments increased just so long as he remembers that his successes must be based on common-sense.

We commend a study of the Address to all thoughtful students at this time, and offer these few lines from it as representing sentiments which are worthy of assiduous cultivation:

. . . "the object of science is to economize thought, just as it is the object of a machine to economize effort. Logically, this definition is justified, and it may be the best that can be given, if we prefer using a technical expression to confessing an emotional feeling. But why should we do so? Is it not better to recognize that human intelligence is affected by sentiment as much as by reasoning? It is a mistake for scientific men to dissociate themselves from the rest of humanity by placing their motives on a different, and at the best only superficially higher level."

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., October 4, 1915.—The news from the front is having a cheerful effect upon the general market. The production of shells is still holding the attention of a large number of our manufacturers, and is progressing at a satisfactory rate. The feeling of uncertainty of producing a shell that will stand a rigid inspection has now passed, and the output of 3.3 and 4.5 shells in both shrapnel and high explosive form has reached the stage, that no future shortage in this connection need be looked for. The attention of many of our shell makers is now directed to the prospects of a heavier type of projectile being required, and in some cases preparations are already in progress for the manufacture of shells up to nine and twelve inches in diameter.

The prospect of field guns being built by Canadian concerns in the near future, has developed several inquiries relative to machine tool requirements; no definite action has as yet been taken in the matter.

Steel.

The steel mills are operating practically to capacity on war stock, and orders are still coming in for rounds, in many cases up to 6 inches diameter. This condition of affairs is likely to be maintained for many months to come.

Pig Iron.

Pig iron is little changed from previous weeks, quotations are generally holding firm, prices on "Victoria" showing an advance of 50c per hundred.

Metals.

Little change is noted in metal quotations, the only metal affected being aluminum, which shows an increase from 50 to 52 cents. The market in tin is dull, a few inquiries being made for October and November delivery. There is, however, little to stimulate buying, and large unsold stocks have a tendency towards a somewhat pessimistic feeling.

Lead remains quiet, expectations of an advance have not been realized. Prices are holding firm.

Spelter remains steady with inquiries for future delivery a little more pronounced.

Antimony is quiet but firm, while aluminum shows a little stronger tone.

Machine Tools and Supplies.

Machine tools are still in strong demand, and with the prospect of the manufacture of larger and heavier type shells in the near future, the enterprise and capacity of the manufacturers is sure to be taxed to the utmost limit to procure reasonable delivery.

Machine shop supplies as may be expected are being used in larger quantities each succeeding week. Quotations on high speed steel are quite indefinite due to the fact that makers have withdrawn price lists, owing to the difficulty in securing the raw material.

Old Material.

The market in scrap metals is fairly brisk, crucible copper has advanced $1.00 per hundred, wire shows a slight increase, while No. 1 wrought iron and heavy melting steel show an advance of $1.00 per hundred. Heavy lead is up to $4.50.

Toronto, Ont., Oct. 5.—An encouraging feature to be noted is the continued increase in our export trade, although this has not as yet done much to improve domestic business. The improvement in the steel trade, referred to later in these columns, is a good indication of the development that is taking place. While the principal development has been in the export trade, it will obviously be of the greatest benefit to the country generally, and will in due course help to stimulate internal trade. There has been for some time, and there still is, a decided tendency to economize in all directions, and consequently development will be restricted until conditions are on a more stable basis, which can hardly be expected until the war is over.

It is, however, satisfactory to note that the Dominion revenues for September promise to be even greater than anticipated. In the Customs revenue alone there is an increase of over two million dollars for the month of September over the corresponding month last year, and an increase of about $1,750,000 for the first half of the present fiscal year. All indications point to a gradual improvement in domestic trade, due largely to war business of various kinds and, of course, to the excellent crops.

The output of shells is rapidly increasing. It is estimated that Canadian plants are producing one million shells per month, and that of this number 17,000 are being turned into fixed ammunition per day. It is announced that the Dominion Steel Corporation have practically completed arrangements for a large order for shell. The Canadian Car & Foundry Co. are making arrangements for sub-letting the last Russian shell contract to American and Canadian firms.

Steel Market

That the steel trade in Canada is now in a prosperous condition is proved by the reports of the Dominion Steel Corporation and the Nova Scotia Steel Co. issued recently. As regards the first mentioned concern, the indebtedness to the bank is being rapidly wiped out by means of profits made principally in export business. It is stated that heavy orders have been received for bars, billets, wire and nails, and that contracts for T.N.T. have proved exceptionally profitable. The coal trade has also been the best in the history of the company.

With regard to the Nova Scotia Steel & Coal Co., the annual statement was considered most satisfactory. The output of shells for September this year was the largest for any month since the manufacture of munitions began, being over 40 per cent. greater than for August. It was reported that the orders on hand would keep the plant at the present high rate of production for at least six months, and that negotiations for further orders were in progress. The Eastern Car Co., a subsidiary of the Nova Scotia Steel Co., is doing well. The first consignment of 250 fifty-ton box cars for the Russian Government has been shipped and will go via the Panama Canal and Vladivostock. The complete order calls for two thousand cars, all of the fifty-ton capacity. The Algoma Steel Co. has booked an order for 17,000 tons of steel rails from the Pere Marquette Railway.

The steel plants continue working to capacity on bars and forgings for shells, there being practically no limit to the demand. The merchant bar business has improved to some extent, but the demand for structural shapes is still very light. Prices on steel products generally are very firm and may go higher. The high-speed tool steel situation is unchanged, and prices will no doubt advance further. The most serious aspect of the situation, however, is the difficulty of obtaining supplies in sufficient quantity, as an enormous amount of high-speed steel is now being used. Prices of galvanized sheets are firmer and have a higher tendency, owing to the recent strength of spelter.

The steel trade in the States is very active, and the demand for steel products of all kinds is increasing. The mills are full up with business, and the export demand for steel rounds for shell, barb wire and other steel products is enormously heavy. There is a great scarcity of Bessemer and open-hearth billets, and prices are very firm, forging billets having advanced to $33 f.o.b. Pittsburgh. Steel hoops are now being quoted at 1.50c Pittsburgh. Prices on

bars, plates and shapes are very firm, with an upward tendency.

Pig Iron

The situation, generally speaking, is unchanged. There is a good demand for steel making pig iron, but foundries are quiet. It is reported that some pig iron is being exported to France. There are no price changes to note this week.

Scrap Metal

The scrap metal market is stronger, particularly for heavy melting steel, copper, brass and zinc scrap. Copper and brass scrap have advanced ½c to 1c per pound; zinc ½c per pound, and heavy melting steel $1 per ton. Wrought iron scrap is now being quoted at $9, and machinery cast iron at $11 per ton. Heavy lead is easier at 4½c per pound.

Machine Tools

The situation in the machine tool trade is practically the same as has prevailed for some weeks. Machine tool builders are working to capacity to fill orders on their books, but deliveries are still very backward. Comparatively few orders for new tools have been placed recently with local machinery houses, although a few of the larger firms making shells are buying single machines, in some cases second-hand tools. In the States there is a big demand for tools, and factory extensions are being held up owing to the difficulty in obtaining prompt delivery. In addition to the domestic demand, it is stated that English, French and Russian buyers are picking up all the machines they can find.

Supplies

The brisk demand for machine shop supplies continues, and prices are holding very firm. Prices of high-speed twist drills have practically been withdrawn, and are only being quoted subject to immediate acceptance. This is due, of course, to the scarcity and price of high-speed steel. Carbon drills have not as yet been affected, although there is a possibility of slightly higher prices being put in force.

Half-and-half solder has declined ½c and is now quoted at 23½c per pound. This is due to weakness in the tin market. Linseed oil has advanced 7c per gallon and is now quoted at 72c for raw and 75c for boiled oil. Turpentine is unchanged at 64c per gallon, but there is a possibility of higher prices.

Metals

The successful termination of the Anglo-French loan negotiations in New York and the rise in sterling exchange to a more normal basis is expected to have a beneficial effect on the metal market. There has been, however, up to the present, no marked improvement, and with the exception of tin and copper there have been no price changes of any particular importance. There has been increased activity in the copper market recently and prices are a little higher. Tin on the other hand has declined, due to weakness in the London market. The spelter situation is unchanged and the market steady. The lead market is firm and the price stationary. The antimony market is featureless, but there is a continued scarcity of aluminum, and quotations have a higher tendency. There is no change in the general situation locally and a brisk demand is reported for metals for munitions, ordinary business being only fair.

Tin.—The market is very dull and consumers are showing comparatively little interest in either spot tin or futures. An over-supply of spot metal is also depressing the market. Tin has declined 1c locally and is being quoted at 38c per pound.

Copper.—The market is firm and higher, due to increased demand. It is believed that stocks are accumulating in the States notwithstanding the heavy consumption; production having reached a record mark. Copper has advanced ½c and is quoted here at 19½c per pound.

Spelter.—The market has a strong tone, due to a scarcity of metal for prompt shipment. The London market is higher, but New York is unchanged and quiet. Local quotations are unchanged at 18c per pound.

Lead.—The market is quiet and featureless. Quotations are unchanged at 6¼c per pound.

Antimony.—The market is quiet and unchanged. On the London market little interest is being taken in antimony, as it is controlled by the Government. Local quotations are unchanged at 35c per pound.

Aluminum.—Supplies of this metal are very difficult to obtain for immediate delivery, except in small lots. Quotations are unchanged and nominal at 55c per pound.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Attache, Russian Embassy, Washington, D.C.

BIG HYDRO PLANS GO TO GOVERNMENT

PLANS for power development that will make the Hydro-Electric system of Ontario independent of all private developments and provide a supply sufficient not only for the next few years, but for many years to come, have been given final approval by the Hydro-Electric Commission and sent on to the Government.

As outlined by Sir Adam Beck at London several months ago upon the opening of the first Hydro radial in the province, the plans call for an initial development of 100,000 horse-power by utilizing the maximum head of power on the Niagara River, now undeveloped. The plants, it is understood, outline a possible supply from this source of 250,000 horse-power and cover as well developments possible from the utilization of the Welland Canal spillways, which will add as much more to the power supply of Ontario.

The construction of a great development plant in the Niagara district has become an urgent necessity by the rapid growth of the cheap power system in Ontario. Sir Adam Beck and his colleagues on the commission, Hon. I. B. Lucas and W. K. McNaught, C.M.G., are facing the end of their present sources of supply. The 100,000 horse-power supply contracted for with private interests at Niagara Falls will soon be exhausted by the increasing demands of the municipalities, which even the big increase in the supply from new plants here and there in the province will not meet. With the advent of Hydro radials on an important scale, the present supply will fall far short, and when that time arrives the commission must be in a position to furnish practically unlimited power.

The commission has received word that the Council of Gravenhurst has passed a by-law approving of a contract with the commission for the sale of the South Falls power plant, owned by the town. This plant is now producing but 500 horse-power, but the commission's engineers have estimated that the output can be immediately enlarged to 1,500, with a maximum horse-power without storage of 2,500 and storage of 4,000. The surplus power will be used to supply municipalities in the surrounding district, which have been pressing the commission for power. The Gravenhurst by-law will be submitted to the ratepayers on October 2.

THE CHEMICAL ENGINEER

IN the modern organization there is room for the research chemist of high and wide attainments, for the scientifically trained engineer, also of wide attainments, and for a type of professionally trained man who is the natural medium of interchange between these two specialists. This intermediary is the chemical engineer. He must be a man of special aptitudes, inasmuch as he must have grasped the chemist's point of view as well of the engineer's. The chemist thinks and works in terms of atoms and molecules and the laws which govern their combination. The engineer thinks of matter in masses which can be moulded to his will by the craftsman, or of mechanical or electrical energy which can be generated, controlled, and measured by machinery. The chemist is the master and director of his own operations, which he can, for the most part, carry out with his own hands. The engineer loses his direct hold on his operations whenever his ideas have been fully committed to paper in the drawing office. It is his special function to organize the labors of many workers. A certain number of men are able to enter fully into the spirit which actuates both types of expert, the chemist and the engineer; they can resist the particular exclusiveness of each, while giving to each its due weight. These are the naturally gifted chemical engineers who in one sense are "born, not made." In our colleges and universities the best that we can do for men of this gifted type is to give them the best possible opportunities for an all-round development of their powers. Dr. G. T. Bellby on "Chemical Engineering."

TO PREVENT accidents we must thoroughly understand their causes. Every danger point in every machine and in every process must be located and definitely grappled with. It is important to report accidents, but it takes less time to prevent them. Two minutes' work or care will often prevent an accident that would lose a man days from work.

CANADIAN COMMERCIAL INTELLIGENCE SERVICE

The Department of Trade and Commerce invites correspondence from Canadian exporters or importers upon all trade matters. Canadian Trade Comissioners and Commercial Agents should be kept supplied with catalogues, price lists, discount rates, etc., and the names and addresses of trade representatives by Canadian exporters. Catalogues should state whether prices are at factory point, f.o.b. at port of shipment, or, which is preferable, c.i.f. at foreign port.

CANADIAN TRADE COMMISSIONERS.

Argentine Republic.

H. R. Poussette, 278 Balcarce, Buenos Aires. Cable Address, Canadian.

Australasia.

D. H. Ross, Stock Exchange Building, Melbourne, Cable address, Canadian.

INDUSTRIAL AND CONSTRUCTION NEWS

Establishment or Enlargement of Factories, Mills, Power Plants, Etc.; Construction of Railways, Bridges, Etc.; Municipal Undertakings; Mining News.

Engineering

Montreal, Que.—It is reported that Gustave Pollien is contemplating the erection of a plant for the manufacture of aeroplanes, etc.

Windsor, Ont.—The Kelsey Wheel Co. will make an extension to their factory at a cost of $10,000. Wells & Gray, of Windsor, are the general contractors.

Walkerville, Ont.—The Canadian Detroit Lubricator Co. will make an extension to their factory. Wells & Gray, Windsor, Ont., are the general contractors.

Collingwood, Ont.—The Imperial Steel & Wire Co. will start operations at their plant early in October. Some delay has been experienced in connection with the contracts.

Gravenhurst, Ont.—The Muskoka Lakes Corporation is contemplating installing a number of small steam pumps at various points for fire protection. W. F. Wasley, of the Muskoka Navigation Co., is manager.

Fort William, Ont.—The Fort William Coal Docks Co., contemplate making an extension to their plant on the Mission River, estimated to cost $200,000. Included in the proposed addition will be a new hoist of a larger size than those now in use on the docks.

Toronto, Ont.—A scheme to provide a water supply for the southern portion of York Township was outlined in the report of Engineer Hugh Gall, submitted to the York Township Council at a special meeting held on September 30. The project as embodied in the report makes provision for all that district lying between the city limits and Eglinton Avenue, a distance of one and one-half miles. It is proposed to lay 12-in. and 6-in. cast iron pipe. The probable cost as estimated by the engineer is $750,000.

New Liskeard, Ont.—Another large pulp and paper mill is to be built in Timiskaming. Sutcliffe & Neelands, engineers, of Liskeard, have been advised to hold themselves in readiness to proceed with work discontinued when war broke out. The location of the proposed mill is some 30 miles west of Cochrane. Three miles of railway are necessary to connect with the Transcontinental Road. It is estimated $2,000,000 will be expended in the construction of this new pulp mill, and American capital is being used.

Electrical

Chatsworth, Ont.—A by-law will be voted on to raise $4,000 for a hydro-electric system.

London, Ont.—The City Council will purchase electrical equipment for the Hydro sub-station.

St. Marys, Ont.—Work is to commence on the new Hydro line from St. Marys to Exeter. The main power line will run from St. Marys to Exeter, passing through Woodham and Kirkton.

Municipal

Walkerville, Ont.—The railway bylaw will be voted on by the ratepayers on October 16.

Dundas, Ont.—The town council passed a by-law to spend $25,000 on the extension of the waterworks system.

East Angus, Que.—It is proposed to spend $5,000 on extensions to the waterworks system.

Thetford Mines, Que.—A waterworks system will be installed at a cost of $12,000.

Blenheim, Ont.—The town council contemplate installing an ornamental lighting system.

Brigden, Ont.—The bylaw to authorize the extension to the lighting plant has been defeated.

Goderich, Ont.—The town council are considering the installing of an electric light and power plant.

East Angus, Que.—The town will make extensions to its waterworks plant to cost $5,000. R. C. Cowling is clerk.

St. Hyacinthe, Que.—A by-law has been carried providing for the installation of a complete gravity filter system, with a capacity of 4,000,000 gallons per day. Estimated cost, $75,000.

Woodstock, Ont.—The ratepayers are asking the council to compel the Woodstock Gas Light Co. to supply purified gas. It is suggested that purifiers be installed by the company.

Sarnia, Ont.—A by-law will be voted on in the near future to sanction the purchase of the local electric light plant by the city.

Montreal, Que.—The city has completed a modern street lighting system through the business portions of the city, on St. Catherine and Bleury, two of the main retail thoroughfares. The turning on of the current for this system will give Montreal its first street illumination of a modern character.

Brockville, Ont.—The Water and Light Commission has decided to call new tenders for the filtration plant, according to revised plans and specifications prepared by the town engineer. One set of tenders have already been received but certain alterations have been made in the plans to suit local conditions.

Port Moody, B.C.—If the electors of Port Moody endorse a bylaw to be voted upon on Oct. 7, the city will become the home of an extensive steel works and rolling mills to be erected there by the Port Moody Steel Works Ltd. The bylaw is one to authorize the city council to make an agreement with the company guaranteeing its debentures to the amount of $100,000.

Winnipeg, Man.—Seven tenders for electric mains, switchboards and circuit breakers for the power house at the new law courts, were opened by Hon. T. H. Johnson, minister of public works, on September 29. The tenders were as follows: The Schumacker, Gray Co., $6,950; Star Electric, $7,000; Electric Motor Sales & Repair Co., $7,985; Goold Engineering and Supply Co., $6,490; The Dominion Equipment and Supply Co., $6,880; Robert McCrea, $6,537.50; McDonald & Wilson Lighting Co., $7,077.

General Industrial

Montreal, Que.—Pilkington Bros. have received a permit for the erection of a new factory.

Chatham, Ont.—The William Rennie Co., Toronto, are building a warehouse and elevator, estimated to cost $20,000.

Petrolia, Ont. — The Marine City Sugar Co. is contemplating establishing a plant, which will cost about $800,000. E. Hyatt, Petrolia, is a stockholder.

St. John, N.B.—Daley & Carvell have purchased a site of 20 acres at Washademoak, N.B., and will build a factory for the manufacture of axes, etc.

Hamilton, Ont.—The Mercury Mills Co. will build a factory here, to cost approximately $250,000. It is expected that construction work will begin shortly.

Medicine Hat, Alta.—W. E. Clarke proposes to establish a plant here for making clay products. A by-law will probably be voted on by the ratepayers on October 25, to ratify an agreement concluded by the City Council.

Ryerson, Sask.—The Saskatchewan Co-operative Elevator Co.'s elevator at this place was destroyed by fire on Sept. 21. The loss is estimated at $8,500, which is fully covered by insurance. The elevator will be rebuilt.

Winnipeg, Man.—Alfred W. Lawson, of New York City, a prominent manufacturer of aeroplanes, etc., has been in communication with Industrial Commissioner Roland with regard to establishing a factory here for making aeroplanes.

Tenders

Ottawa, Ont.—Tenders for examining warehouse fittings, Fort William, Ont., will be received until Thursday, October 14, 1915. Plans and specifications may be seen on application to J. C. Stinson, clerk of works, Fort William, Ont.; Thos. A. Hastings, clerks of works, Postal Station "F," Toronto, Ont., and at the Department of Public Works, Ottawa.

Ottawa, Ont.—Tenders for public building fittings, Three Rivers, P.Q., will be received until Wednesday, October 13, 1915. Plans and specification may be seen on application to Chas. Lafond, architect, Three Rivers, P.Q.; to R. L. Deschamps, overseer, Montreal Central Post Office, and at the Department of Public Works, Ottawa.

Ottawa, Ont.—Under the direction of the Honorable the Minister of Militia and Defence, certain old stores, consisting of leather, 2,700 lbs.; leather, buff, 335 lbs.; wrought iron, 4,200 lbs.; scrap steel, 116 lbs., and other stores, comprising canvas, rope, rubber, tarpaulins, mattresses, etc., are for sale by public tender until October 15. These stores may be seen on application to the senior ordnance officer, Old Fort, Toronto, daily, between the hours of 2 p.m. and 6 p.m., Saturdays and Sundays excepted. Eugene Fiset, Deputy Minister, Department of Militia and Defence, Ottawa.

Toronto, Ont.—Tenders will be received, addressed to the chairman, Board of Control, up to Tuesday, October 12, 1915, for the construction and delivery of 36-inch stop valves, valve operating mechanism and special castings, for main pumping station. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Ottawa, Ont.—Tenders will be received up to Tuesday, October the 19th, for the undermentioned items for delivery to H.M.C. Dockyards at Halifax, N.S., and Esquimalt, B.C.: Brass bars, antimony, iron firebar, brass sheets, aluminum, pig iron, brass tubes, steel angles, iron angles, copper sheet, steel boltstaves, iron boltstaves, copper tubes, steel plates, iron sheets, zinc plates, steel sheets, India rubber, lead, milled steel for tools, sheet packing, or sheet, etc. Forms of tender and all information may be obtained by application to the undersigned, or to the Naval Store Officer at H.M.C. Dockyard, Halifax, N.S., or Esquimalt, B.C. Applicants for forms are requested to state definitely the item or items on which they desire to tender. G. J. Desbarats, Deputy Minister of the Naval Service.

Building Notes

St. John, N.B.—It is reported that large extensions will be made to the warehouses at the Sand Point docks here.

Toronto, Ont.—The erection of fire stations at Earlscourt and Wychwood, is contemplated. Plans have been prepared and sites purchased.

Toronto, Ont.—The city architect has issued a building permit to the Board of Education for the erection of a three-storey brick addition, costing $51,500, to the North Toronto school on Eglington avenue, near Brownlow avenue.

Toronto, Ont.—The Toronto Furniture Co. have applied to the City Architect's Department for permission to build a $12,000 factory on Dufferin street near Liberty street. This will be used for the purpose of making boxes for the shipment of shrapnel shells.

Toronto, Ont.—The Board of Control has granted to the Dominion Government a permit for the erection of a temporary post office at the south-east corner of Front and Bay Streets. It will be 100 by 200 feet, clad with steel, two storeys high, with flat roof.

Preston, Ont.—The Hydro-Electric Commission has just completed arrangements for the erection of six transformer station storehouses in Guelph, Preston, Berlin, St. Mary's, Woodstock, and Cooksville. The buildings will be 36 by 60 feet, and will be of metal construction throughout.

Toronto, Ont.—The Board of Education proposes to build a large new school on Gledhill avenue, East Toronto, at a cost of $55,400. An application has been made for a permit for this work. The Architect's Department has issued a permit to the Board for the erection of a three-storey brick school on Eglington avenue, near Brownlow avenue. The structure will cost about $51,500.

New Incorporations

The France & Canada Steamship Co. has been incorporated at Ottawa, with a capital of $1,000,000, to operate a line of steamers between Canada and France. The head office will be in Montreal, Que.

The Standard Toys, Ltd. has been incorporated at Toronto, with a capital of $40,000, to carry on the business of manufacturing toys, etc., at Toronto. Incorporators, John Anthony Chantler and Ernest Walter Chantler, of Toronto.

The Franco-Canadian Chemical Co. has been incorporated at Toronto, with a capital of $1,000,000, to manufacture drugs and chemicals, at Toronto, Ont. Incorporators, Robt. Alexander Stephen and Adam McGowan Cook, of Toronto, Ont.

The Dominion Brake Shoe & Foundry Co. has been incorporated at Ottawa, with a capital of $200,000, to manufacture all kinds of brake shoes at St. Thomas, Ont. Incorporators, James Stellar Lovell and William Bain, of Toronto, Ont.

The Dome Consolidated Mines, Ltd. has been incorporated at Toronto, with a capital of $3,000,000 to acquire and develop mineral lands and deposits. The head office of the company will be at Toronto. Incorporators, Charles Henry Manaton and Arthur Hodgetts, of Toronto, Ont.

The Montreal Engine Packing Co. has been incorporated at Ottawa, with a capital of $20,000, to take over the business carried on under the name of Montreal Engine Packing Co. at Montreal. Incorporators, Edgar Alexander Wright and Gordon Balfour Kingan, of Montreal.

The Canadian Duplex Steam Trap Co. has been incorporated at Ottawa, with a capital of $40,000, to manufacture steam traps and other appliances, at Walkerville, Ont. Incorporators, Joseph Hector Mailhot and Thomas George Rakestraw, of Detroit, Mich., and Harry Owens Kerr, of Walkerville, Ont.

Manufacturing Tin Powder Cups for Shrapnel Shells

Staff Article

The various component parts which enter into the construction of shrapnel shells call for work of considerable variety. While powder cups are simple in form, the exacting requirements demand the use of accurate methods and every care in workmanship and material.

TO secure the proper results from the discharge of a shrapnel shell the charge of bullets and resin contained in the shell must be discharged when at a certain distance from the desired target. To accomplish this object, a time fuse is ignited by percussion at the time the shell is discharged from the gun. During the period of flight this fuse burns through channels previously set by adjustment of the time fuse, which at the appointed time connects with a quantity of explosive powder at the base of the shell.

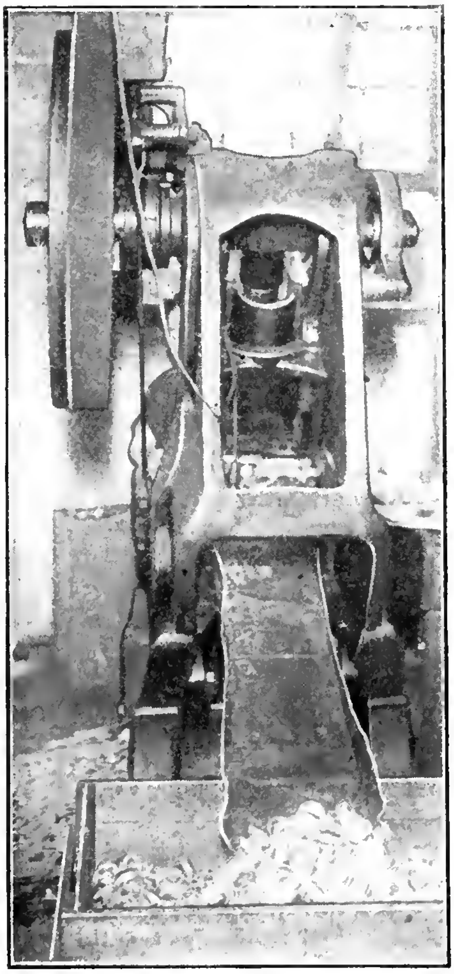

FIG. 1. FORMING POWDER CUPS ON POWER PRESS.

In the British shrapnel shell this explosive charge is contained in a small tin plate cup, which fits the chamber prepared in the base of the shell. Directly above this powder cup and separating it from the charge of bullets and resin is a steel diaphragm, which when discharged forces the bullets and resin out through the nose of the shell in the form of a spray, at a velocity of from 200 to 300 ft. per second in excess of the velocity of the shell at the time of shrapnel discharge.

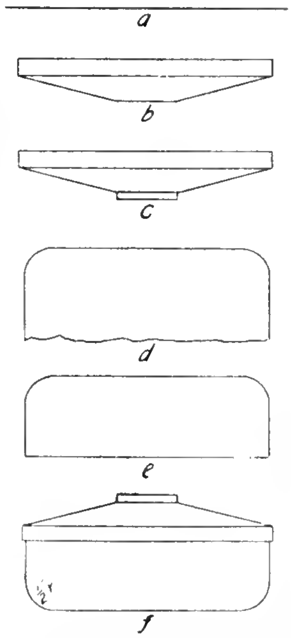

FIG. 4. POWDER CUP FORMING PROCESSES.

The production of these tin powder cups forms one of the many problems that the manufacturers of this country have met and overcome.

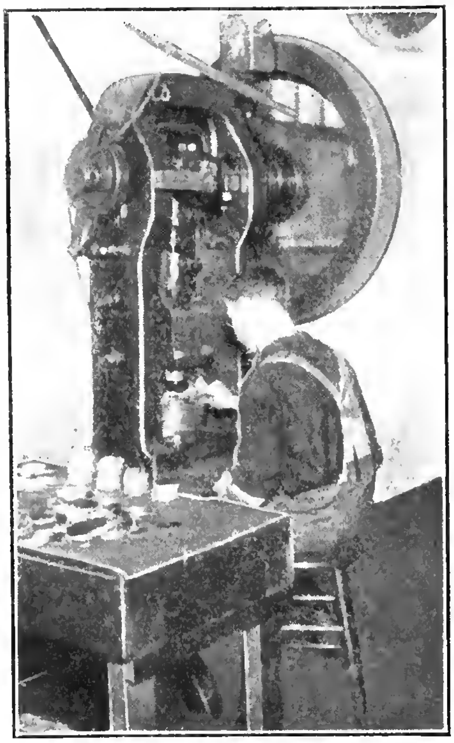

FIG. 5. FORMING COVERS FOR CUPS

Forming the Cup.

The various operations for the completion of this necessary part of the shrapnel shell is here given.

The first operation on the base of the cup is performed in a combination die

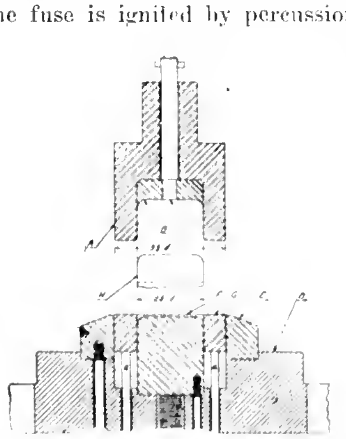

FIG. 3. COMBINATION DIE FOR FORMING POWDER CUPS.

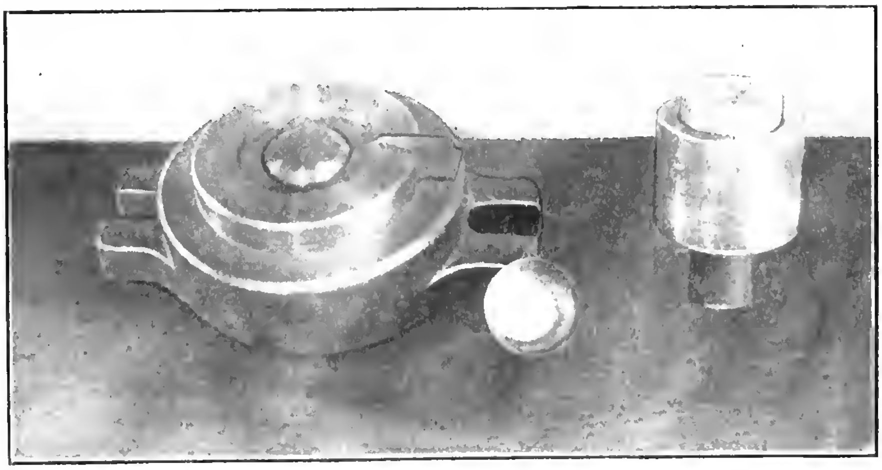

FIG. 2. FIRST OPERATION TOOLS FOR BASE OF POWDER CUP

on the press, shown in Fig. 1. A closer view of this die is seen in Fig. 2, with a view of the cup as it comes from the die. The general construction of the die is shown in Fig. 3. The punch A is made of cast steel, recessed and bored to receive the knock-out piece B and ejector bolt C, which is riveted securely to the knock-out.

The joint between the base and the cover must be firmly soldered. This is done by placing the cup in the jig shown in Fig. 7, and revolving while the solder is being applied. The casting A is secured to the bench B. The stem of the piece C is turned a free running fit in the hole in the casting and pivoted on a sharp point shown, allowing it to turn

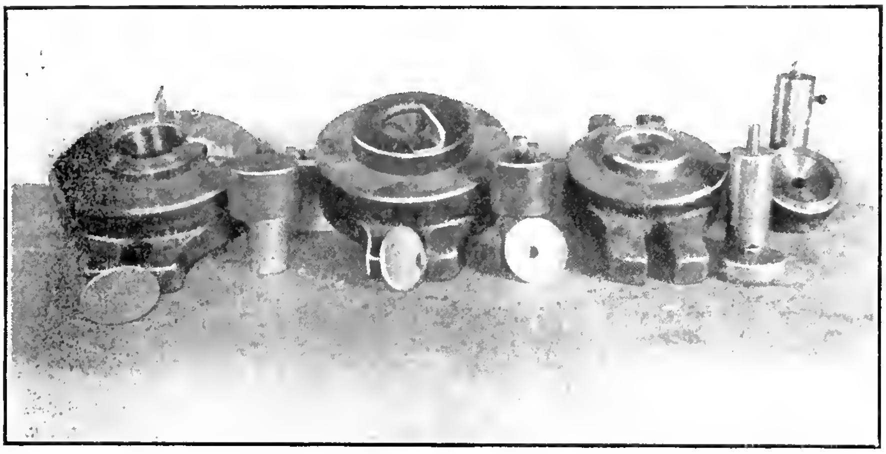

FIG. 6. CLOSE VIEW OF TOOLS FOR PRODUCING POWDER CUP COVERS.

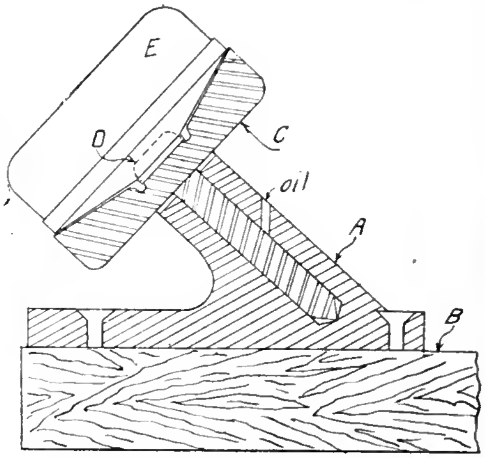

FIG. 7. POWDER CUP SOLDERING JIG

In the die bed D is secured the cutting ring E. The forming post F is placed in a counterbore in the centre of the die bed and secured by means of three screws. The draw ring G is supported by means of four 3/8-in. pins (a) (a). These pins in turn are supported by a plate encircling a rod screwed into the tapped hole in the base of the die. The pressure is derived from the use of a cylinder of rubber between two plates and about the projecting rod.

The piece H is a sketch of the cup as it comes from the die, also shown at (d) Fig. 4. These cups are then placed in a small chuck on a speed lathe and trimmed, as shown at (e) Fig. 4.

Making the Cover and Soldering the Cup

The first operation on the cover is blanking the disc, which is 2 19-32 in. in diameter and .022 in. thick.

The second operation shown at (b) Fig. 4 is shaping the piece, which is performed in the press operation seen in Fig. 5. The next operation is piercing the hole in the centre, followed by the throwing up of the flange, as shown at (c) Fig. 4. Following this operation, the two pieces are placed together in a press, Fig. 8, and firmly forced to their final position, as shown at (f) Fig. 4.

freely. A pilot D is turned on the piece C for centering and holding the cup E while being soldered.

THE MUNITION SITUATION

A REORGANIZATION of the Canadian Shell Committee, under General Bertram, and further large orders for the heavier types of shells, with the possibility of orders for the manufacture of heavy guns for the British Government in Canada, were amongst the announcements made by D. A. Thomas, the representative of Mr. Lloyd George, Minister of Munitions, in Canada, at a luncheon given in his honor at the Windsor Hotel, Montreal, by the local branch of the Canadian Maufacturers' Association on Friday last. There was a large gathering, representative of many of the large manufacturing concerns in Montreal, and the keenest interest was displayed in Mr. Thomas' utterances.

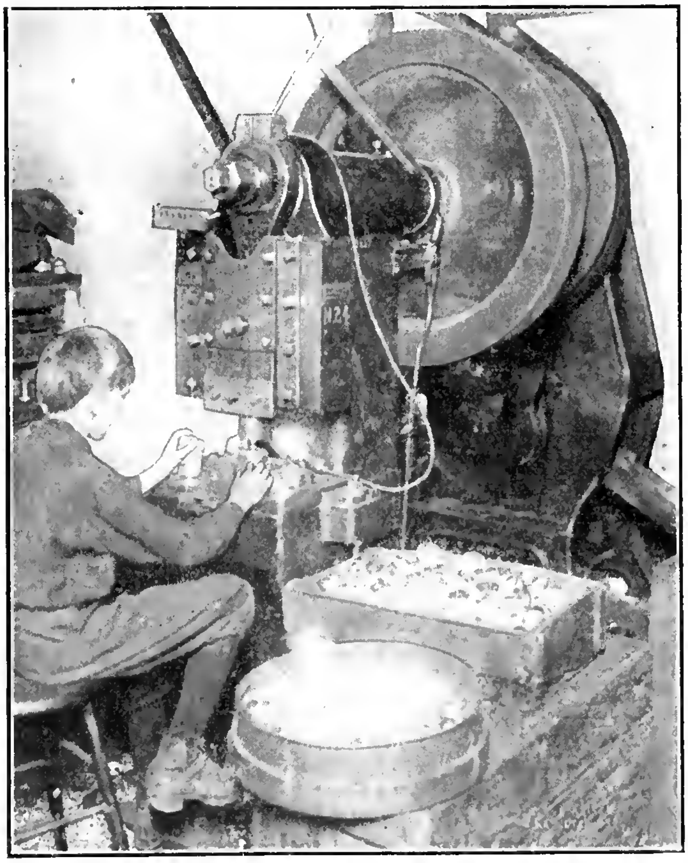

FIG. 8. PRESSING COVER ON POWDER CUP.

For the reorganization of the Shell Committee Mr. Thomas said that with the consent of General Bertram two of Britain's greatest munitions experts, Sir Frederick Donaldson and Mr. Lionel Hichen, were now on their way to aid in this work, and advise with regard to heavy shells and guns.

As to the charge that too many shell orders had gone to to the States and too few to Canada, Mr. Thomas intimated that economy had to be considered, and in the past Canadian manufacturers had been slow in delivery, and higher in price than either the States or England. He, however, stated that the British Government was anxious to give every possible preference to Canada, without sacrificing efficiency, promptness of delivery, or economy of cost.

The British representative also took occasion to reply to the recent interview given by Herbert Holt, criticizing the attitude of the British people in this war. He quoted many instances to prove that the British people were really taking the war seriously.

PRODUCTION METHODS AND DEVICES

SHELL EQUIPMENT IMPROVEMENTS.

By J. H. Moore.

IT is a well known fact that the older and more established a particular process of manufacture may be, there is just that longer a chance to improve on what at the outset appeared to be first class in every respect. The same applies to the manufacture of munitions, and in the following article, the writer will place before the readers, recent improvements in equipment in the manufacture of 18-pounder shrapnel shells.

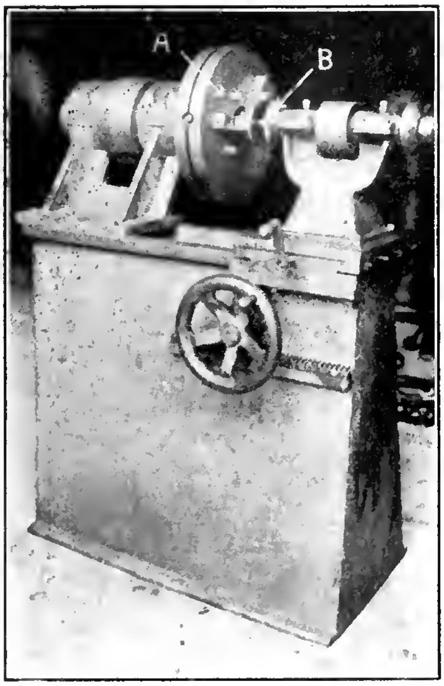

FIG. 1. SPECIAL GRINDER FOR SHELL BASES.

One firm, which has been turning out a considerable quantity of these shells, have found that great trouble is experienced in getting the base of shell just right, both as to size and finish, as the inspectors are very particular of this point. To make sure that all are similar there has been designed and built the machine shown in Fig. 1. It is what might be termed a special purpose grinder, as being built for this work only.

The chuck A is of the three-jaw universal type, allowing the shell to be quickly and accurately adjusted in position. The shell is gripped around the body just above the driving band, leaving the base end exposed. The grinding wheel is mounted between the driving flanges B, the spindle being carried by a grinder head, which is arranged to slide crosswise on the carriage C.

In addition to facing the base end of the shell, the wheel is used to grind the outside diameter of the base, thus necessitating a longitudinal motion by means of hand wheel and rack, as shown on the front of the machine.

In Fig. 2 is shown an improved type of mandril or boring bar used on the inside of the shell. This bar does three operations in turn—namely, the finishing of powder chamber at bottom, the facing of powder chamber shoulder, and the facing of shell to length. Cutter "A" finishes the bottom of chamber. Slot "B" shows where the cutter to finish shoulder goes in; while four slots "C" show where the cutters for facing off to length are placed. The two last cutters have considerable adjustment, as can be clearly seen, and this fact will be keenly appreciated by those who have figured on this type of work. The hole "D" is for internal oil feed, and as bar is hollow, all cutters are well supplied with lubricant.

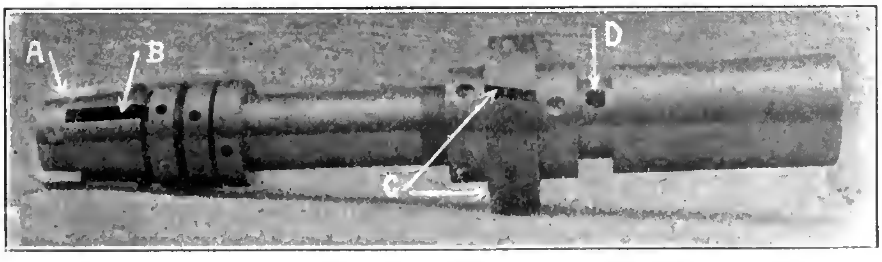

FIG. 2. ADJUSTABLE SHELL ARBOR.

Fig. 3 illustrates a very handy chuck for shrapnel plugs, and one which is not only quick in action, but also extremely accurate. The chuck jaws proper are shown at "A," and are in four parts. A small spring is placed between each jaw for obvious reasons. The body "B" is threaded internally, and screws on a hub on flange "C," which is mounted on the spindle of the machine. The jaws are tapered 18 degs., and this is found to be ample to work satisfactory. To give double driving power to this chuck, a square plug with round shank is placed in hole "D." This square portion of plug engages with square hole in shrapnel plug, and so drives from both this hole and outside diameter, where chuck grasps. Holes E are provided for tightening up body B by means of a pin wrench or bar F.

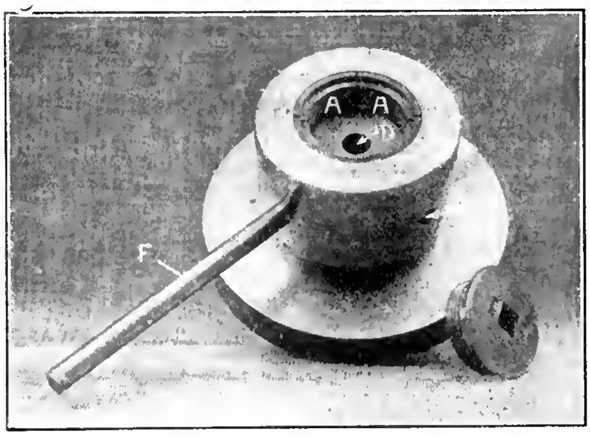

FIG. 3. CHUCK FOR SHELL PLUGS.

AN INTERESTING CURLING FIXTURE

By L. E. Gehman

THE illustrations herewith show a typewriter part and a fixture for curling it to the shape shown. Before curling, the part is cut off and bent with press tools, not shown, as not being of much interest.

To load the fixture shown, the clamp lever A is swung back and the pin B engages with projections C on the sides of the clamp D, thus raising the latter. The clamp is fastened to the body L of the fixture by blocks S and swings on pin R. The blank is placed on the nest E which is machined or profiled so that the blank fits the nest very firmly, the nest being made from a piece of rectangular cold-rolled steel, with rack teeth cut on the under side.

In operation, the rack is engaged by the pinion F which has just a sufficient number of teeth to cause enough movement to perform the operation. The rest of the pinion is left blank to act as a

stop and prevent the operator from disengaging the rack and pinion.

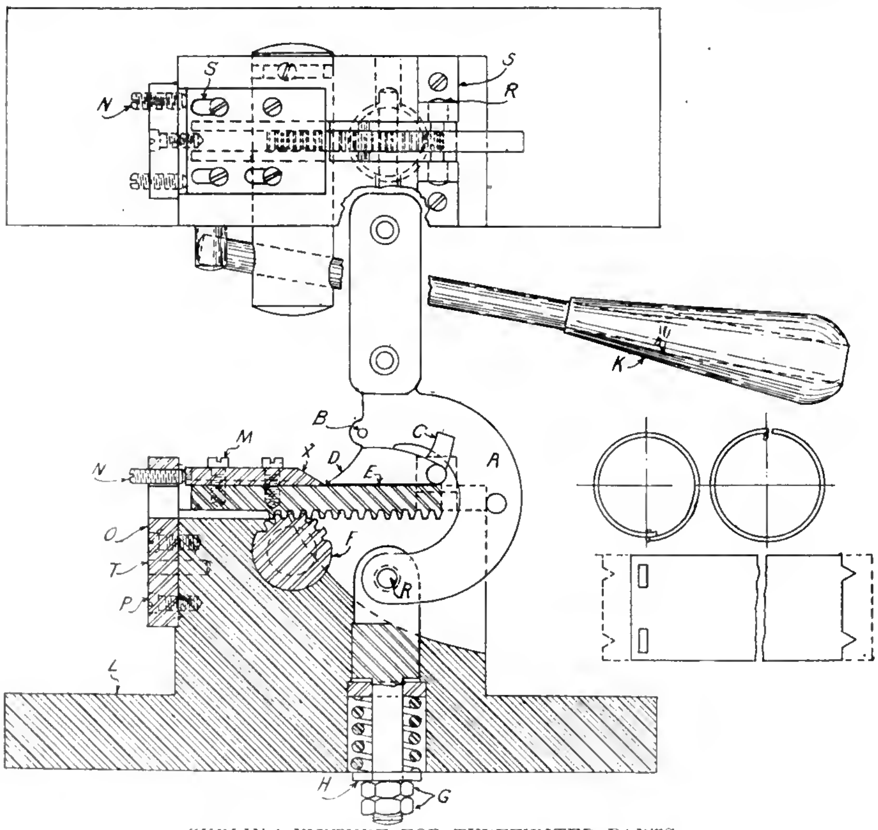
After the blank is placed in the nest E, the clamp lever is drawn toward the operator, forcing the clamp D on to the piece to be curled. The force which the clamp exerts against the piece is regulated by the nuts G and spring H. The latter is adjusted so that there is a good sliding fit between the clamp and the work.

The piece is now ready to curl and the next move is to pull the lever K toward the operator. To this lever is attached the pinion F, which moves the rack and nest forward, and in doing so, the blank is forced against the curling tool which is of tool steel, hardened and ground, and is beveled to an angle of 30 degrees.

The curling tool is fastened to the east iron body L by the screws M, and the holes are elongated as shown to allow for adjustment. The adjustment of the curling tool is made by screws N which are in the bracket O, the latter being fastened to the body by screws P and dowels T.

As the blank is forced against the curling tool, the end of it slides up over the beveled edge, its outer fibres on the side which strikes the curling tool are stretched, and the opposite side contracts, causing the blank to bend up into a circle.

If the blank does not curl enough, the curling tool R is moved nearer to clamp D, and if it curls too much, the tool is moved in the opposite direction until satisfactory adjustment is made.

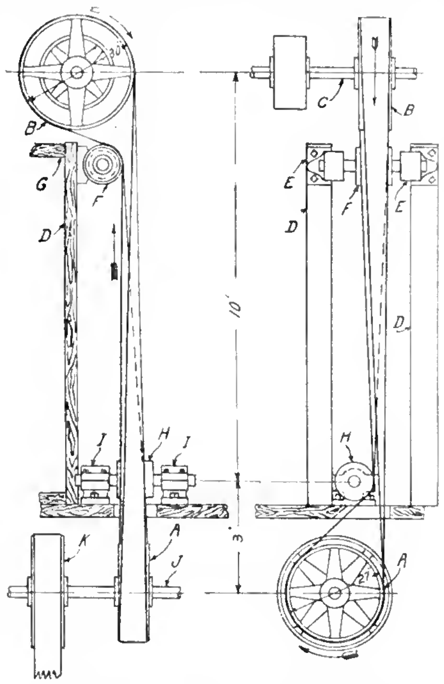


CURLING FIXTURE FOR TYPEWRITER PARTS.

QUARTER TURN DRIVE

By J. H. R.

THE accompanying sketch shows a quarter turn drive employed in the John McDougall Caledonian Iron Works, Montreal, to drive a large planer. While the arrangement may not be original, it may be of some interest to our readers. The position of the planer was such that the counter shaft J would come at right angle to the line shaft.



LAYOUT OF QUARTER-TURN BELT DRIVE

The cut illustrates the method adopted to obtain the desired drive. The counter shaft for the planer is placed so that the lead of the pulley A comes directly below the face of the pulley B, which is on the line shaft C, the latter being located on the gallery above the main floor. The two planks D were erected to support the brackets E which carried the counter shaft on which the idler pulley F is secured. The planks D are kept in position by the brace G. The idler H is secured to the shaft that revlves in the brackets I; these being fastened to the floor as shown. The drive is through an 8-inch double belt, and has given satisfactory service over a considerable period.

STORAGE OF COAL

UNFORTUNATELY, coal does not improve with keeping, but opinions differ considerably as to the extent by which it deteriorates, and as to the means most likely to preserve it economically. Having got some thousands or tens of thousands of tons of coal, preferably at a time when the market price is down, what is the best means of preserving the fuel?

Three methods of storage at least are available. The coal may be piled in stacks, in the open or under cover; or it may be put in bunkers; or it may be placed in tanks which are then filled with water. Bunker storage is limited by considerations of capital cost to relatively small amounts of coal, but is specially convenient for temporary storage, e.g., holding a day or two's supply for the washeries of a colliery or holding fuel on its way—through the bunkers—to a boiler installation. The cost of a tank store is less than that of an equal overground bunker capacity, and is justified in very much larger sizes by the advantages of wet storage.

Ordinary pile storage is the simplest and cheapest system, but it exposes the fuel to "weathering" action, the effect of which is to weaken the coal mechanically, reduce its heating value and introduce a certain risk of spontaneous combustion.

DEMAND FOR NUTS, BOLTS, RIVETS, ETC.

INQUIRIES are being received for nuts and bolts of various sizes. In normal times large quantities are manufactured in the United Kingdom for home use, but the manufacture has been discontinued or curtailed by many factories owing to the utilization of their plant and labor for the making of munitions. In addition, large quantities are annually im-

ported. The United States and Belgium were the main sources of supply before the war, but naturally imports from the latter country have ceased.

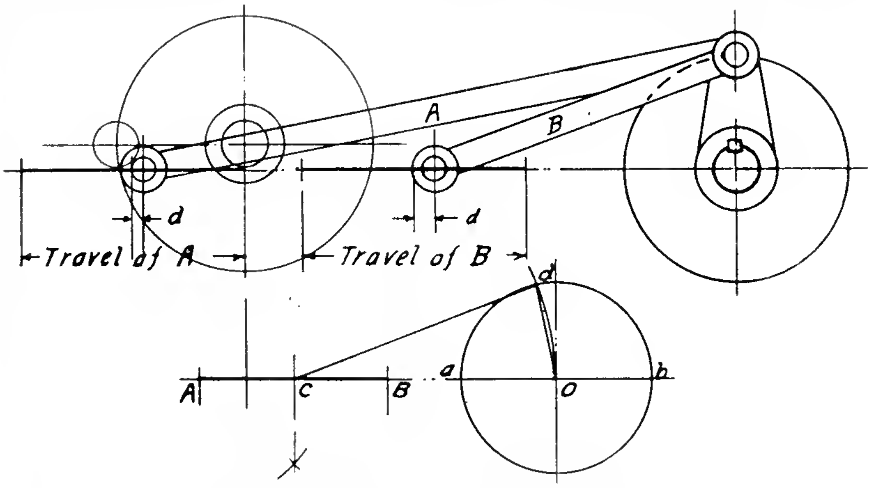
There is also a brisk demand for nails, screws and rivets of all sizes. Manufacturers who are in a position to supply these, or nuts and bolts, should forward a range of samples which will be placed before prospective buyers. In addition, manufacturers are invited to communicate direct with about twenty buyers whose names and addresses may be obtained from the Department of Trade and Commerce, Ottawa.

Questions and Answers

Question — (a)—In a reciprocating engine, is the crosshead and piston in the center of the stroke when the crank pin is midway between the front and dead centers?

(b)—If not, what is the position of the crank when the piston is in the middle of the stroke

Answer—(a) — No. the reason for



PISTON AND CROSSHEAD LOCATION QUERY.

same being due to the angularity of the connecting rod. The relative difference may however, be reduced somewhat by increasing the length of the connecting rod. The space(d) is the distance that the crosshead is nearer the crank center when the crank pin is in a vertical position.

(b)—The skeleton sketch shows the position of the connections when the crosshead is midway in its stroke. The travel AB of the crosshead will equal the diameter a—b of the crank pin circle, therefore the distance c-o will equal the length of the connecting rod. Striking an arc with center at C and length C-O will give the position A of the crank pin when crosshead is in a central position.

* * *

Question—Sometime ago while turning a shaft, I was asked by a clerk for its weight, after considerable material had been removed. There being no tables at hand we made a guess at the weight. Is there any rule for finding the weight of round iron shafting?

Answer.—A fairly accurate method is to divide the square of four times the diameter by six, and multiply this by the length in feed. Example:—To find the weight of a piece of 4 inch round shafting, 3 ft. 8 ins. long, the above rule expressed as a formula becomes.

$$W = \frac{(4d)^2}{6} \times l = \frac{(4 \times 4)^2}{6} \times 3\frac{8}{12} =$$

$$\frac{16 \times 16}{6} \times \frac{44}{12} = 156\tfrac{1}{2} \text{ lbs. nearly.}$$

* * *

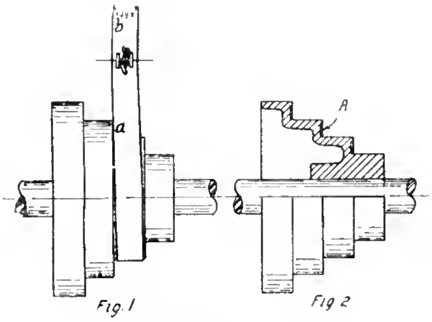
Question—What proportion of oxygen and acetylene burns in a blowpipe when welding by oxy-acetylene?

Answer—The ideal proportion should be 1 cu. ft. of oxygen to 1 cu. ft. of acetylene. In practice a little more oxygen is burnt than acetylene but the proportion of acetylene to oxygen should be as nearly as possible one to one. The same blowpipe using too high a pressure of oxygen will render this proportion less advantageous.

* * *

Question—What is the cause of a belt always having a tendency to climb up on to the larger step of a cone pulley? Sometimes it succeeds in climbing and this often results in the breaking of the belt, or it may commence to climb and twist completely over.—K. L.

Answer—The climbing of a belt may result from one of many causes or from the combination of several. The two cones may not line up with one another, the shafts may not be in alignment, the belt may not be properly laced or an accumulation of grease or belt dressing adhering to the side of the cone may result in trouble stated. If the joint is not properly cut and laced, as shown in Fig. 1, the portion between a and b will extend beyond the path of travel of the rest of the belt, and this section will want to climb. A very common cause of trouble is the use of too much belt dressing which in time gathers on the side of the cones. The belt in its motion comes in contact with this and causes trouble. Care should be taken



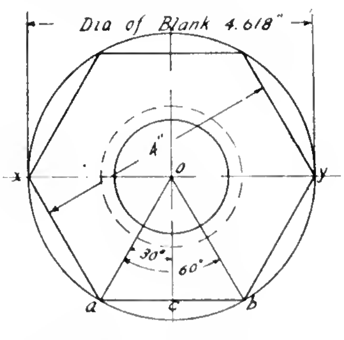
BELT CLIMBING QUERY.

to keep the surfaces of cone pulleys as free from dirt and grease as possible. All cone pulleys or those having flanges should have their sides undercut to reduce the belt friction as shown at (a) in Fig. 2. By this method, the belt only has a bearing on the sides of the cones at two points. Proper attention to belts is one of the chief essentials to successful production.

* * *

Question—What diameter of blank is required to obtain a hexagon which is to measure 4 inches across the flats?

Answer—As shown in the figure the diameter of blank will be equal to the length of the diagonal (x—y). As half the distance across flats (o—c) will equal 2 inches we have one side of the right triangle A C O. To find the length of hypotenuse (o—a) we have from the functions of trigonometry.



DIAMETER OF BLANK QUERY.

$$\text{hypotenuse} = \frac{\text{side adjacent}}{\text{cosine}} =$$

$$\frac{O—C}{\text{cosine of 30 deg.}} = \frac{2}{.86603} = 2.309 \text{ ins.}$$

Then diameter of blank = 2.309 × 2 = 4.618 inches.

NEW PROCESS DEVELOPMENTS

Inventive Genius and Research Operate to a Dual End — They Aim to Improve What We Now Possess and Bring to Our Service Commodities Before Unknown

PROTECTIVE COATINGS FOR METAL*

By H. B. C. Allison**

THIS brief review of some of the processes at present in use for protecting metals from oxidation will be confined to two types: firstly, that in which the metal itself is made more resistant, usually by some chemical treatment; and secondly, that in which another metal is used as a surface coating.

In the first instance, a coating is formed which must possess the following properties, if it is to be successful: It must be homogeneous, continuous, resistant to attack by acids or alkali, firmly attached to the base metal and must have a similar expansion coefficient. The ideal metal coating should also be homogeneous and continuous, but should be strongly electropositive to the base metal and should form electropositive alloys with it, so that in case of oxidation the coating will be attacked and the base metal protected.

As iron is the metal most commonly used as the base, the processes chosen will be those used for its protection, although some may be applicable to other metals. It was known for a considerable time before any process was devised that the black or magnetic oxide formed on iron, under certain conditions, was a very fair protective coating. Attempts to control and improve this coating have led to a number of patented processes, of which two may be taken as typical.

Bower-Barff Process

The pieces to be treated are heated to a temperature of 900 deg. C. in a closed retort. When this temperature has been reached, superheated steam is admitted for 20 minutes and a coating consisting of a mixture of red and black oxides is formed. Producer gas is then substituted for the steam and allowed to act for the same length of time. After cooling somewhat, the pieces are oiled and a smooth, green-black coating is produced, which affords efficient protection from sea water, acid fumes, etc., and will stand a wide variation in temperature.

Gesner Process

This is a further development of the foregoing process. The pieces to be treated are maintained at 600 deg. C. for 20 minutes, after which steam at low pressure is let in at intervals for 30 minutes. The steam, on entering, passes through a red hot pipe at the base of the retort, and is thus partially decomposed into hydrogen and oxygen. After this treatment a small quantity of naphtha or hydrocarbon oil is introduced and allowed to act for 15 minutes to reduce any red oxide, and also to carbonize the surface. The coating is said to be a compound of iron, hydrogen and carbon, and analyses have shown that a minimum of 2 per cent. hydrogen is present. It is an improvement on the Bower-Barff process in that the danger of warping, due to high temperature, is removed, the size of the piece is practically unaltered, and the tendency to scale is much less.

Both processes are quite expensive, but users have usually found the protection afforded of sufficient benefit to warrant the added expense.

Protection by Chemical Means

There is one process which may be of interest in this connection, known after its inventor as "Coslettizing." The pieces to be coated are first cleaned as usual, either by pickling or sand blasting, and are then placed in a boiling water solution of phosphoric acid, in which iron or zinc filings are always present. The period of treatment is from one-half to three hours, depending on the thickness of the coating desired. After drying, the pieces are usually oiled. By this treatment a very slight amount of the surface of the article is converted into certain phosphates of iron, but most of the coating comes from the solution itself.

This coating has been found to be particularly useful in the tropics, and is employed in one instance for typewriters. It is not a complicated process or an expensive one and the finish is very durable. It is, however, subject to patent restrictions.

Protection by Another Metal

The agent used in the majority of cases for protecting iron is the metal zinc. Zinc is strongly electropositive to iron and so are its alloys, if free from impurities. It is also readily available and may be applied by a number of processes.

Hot Galvanizing

The oldest process is that of hot galvanizing, which consists simply of cleaning the piece, coating with a suitable flux and then dipping in the molten zinc. The piece is usually wiped after this to improve the coating. This process has the disadvantages of limiting the thickness of the coat, of plugging any small holes, of the composition of the coating being variable, and the possibility of including injurious and corrosive substances in the coating, which may cause early failure.

A modification of this process is known as the Lohman process. After cleaning, the article to be coated is dipped in the Lohman bath, which is a solution of hydrochloric acid, mercuric chloride and ammonium chloride; it is then dried before immersing in the molten metal, which may be any one or a mixture of a number of metals such as lead, zinc, and tin. The chief point in its favor seems to be that the junction between the iron and the protective alloy is kept free from all oxide, and, therefore, the alloy will fill all the pores and no corroding agent can be included.

It is claimed by its backers that a graduated alloy is formed so that the protective coating cannot be completely broken through except by breaking the sheet itself.

Cold Galvanizing

Another process being used more and more as it is improved is that of wet galvanizing or electroplating. In this case the article to be coated is suspended as a cathode in a suitable bath and is subject to easy control. It provides a coating of high purity and uniform thickness in general, but recesses and corners cause some trouble. It is liable to be more or less porous and may contain acid which will eventually cause failure. In both of these processes, hot or cold, the coating does not become intimately connected with the base metal through deep alloying.

Sherardizing

The latest process of this type is sherardizing, and it is undoubtedly the most perfect as a protection. The object to be sherardized is placed in an iron drum which is filled with a mixture of finely powdered zinc and zinc oxide in varying proportions, and is heated in a reducing or inert atmosphere for a period of time, the length of which depends on the thickness of coating desired.

The coating so obtained consists of four protective layers. Next to the pure iron is an alloy C, rich in iron, upon which is another definite alloy B, containing more zinc. Then there is a layer containing a number of more or less unknown alloys, and finally a layer of pure zinc. This makes a coating which is not easily broken down and which is continuous. The principal objections to its use are the high tempera-

*General Electric Review.
**Of Reserch Laboratory, General Electric Co.

ture to which the piece must be subjected and the increase in size which may be caused.

The theory which has been advanced to explain this process is interesting in that it may be considered as a distillation process. The zinc dust which is obtained from the zinc smelters is said to be in a state of unstable equilibrium, so that in contact with the hot iron it undergoes a change tending to restore it to the normal condition. During this change some of it alloys with the iron, thereby lowering the vapor pressure for zinc in that region. A slow distillation then begins from the zinc nearest the object itself. As the alloy becomes richer in zinc the difference in vapor pressure becomes less and less and then finally becomes zero. This is found to be the case in practice. The deposition becomes slower as the time is extended.

Calorizing

This recently developed process makes use of aluminum as the protective metal and is of particular advantage in preventing oxidation at high temperatures. The protective action is due to the oxide formed by the action of heat on the protecting metal, rather than to any electrolytic relations between the aluminum and the base.

It has been found very useful in the case of iron utensils subject to direct contact with flames at temperatures up to 1,000 deg. C., and also in the case of boiler tubes, for the life is increased many times by this treatment and the saving in the cost of replacements is much greater than the additional initial cost of calorizing.

Schoop Process

One of the most recent processes, and one of the most promising, is the Schoop process. This is applicable to the deposition of metals or alloys on any sort of an object. The apparatus consists of a pistol into which the coating metal is fed as a wire. It passes through a straightening and centreing device into the nozzle, where it is fed through a burner whose temperature may be regulated from 700 deg. to 2,000 deg. F. The molten metal is carried a short distance by the gas current and is suddenly caught by a powerful blast of compressed air which shoots it out of the nozzle with a velocity of 3,000 feet per second, directly on the object to be coated, which is held a short distance away. The coating is homogeneous, continuous, and of any desired depth, and is also exceedingly intimate.

The theory of the Schoop process as given by its inventor, is that the gaseous medium used is much larger in volume at any moment than the drop it has pulverized and is carrying, and the gas is expanding so rapidly that its temperature is far lower than that of the spray. A rapid exchange of heat, therefore, takes place between them, which consolidates the molten particles and gives them a temperature far below the melting point. If the particles arrived in a liquid state at the base with the observed velocity of 3,000 feet per second, they would simply splash on the surface and largely rebound. As a matter of fact they impact and inter-penetrate freely, and the later bombarding particles unite with the earlier ones to form homogeneous compact bodies.

In accounting for the observed action of the Schoop spray at the receiving base, it is supposed that the cooled particles of the metal just before impinging with great velocity on a hard surface, are in an abnormal physical condition. Due to the heat of collision they pass directly into a vapor which condenses and solidifies on the relatively cold receiving body, penetrating by osmotic pressure the superficial pores of the base when an affinity for the latter exists, and otherwise driven in by the pressure behind it. In either case it condenses and solidifies after penetration, and is effectively dovetailed into the base. The hammering and bombardment of the solidified first coat by the minute succeeding particles is practically a process of cold working. The entrained particles liquidify and solidify so rapidly that the metal has not time to return to its natural crystallized state."

There are many other processes in use, those outlined being chosen as representative of the various different means employed to obtain the desired protection because of their prominence, or of some new feature which they contain.

CO-EFFICIENT OF FRICTION OF BELTING MATERIALS

AN investigation has been made for a firm of belt manufacturers into the properties of driving belts of various materials. Determinations were made of the co-efficient of friction with different values of tension on the belt and also of the stretch for different loads. In order to determine the co-efficient of friction, the belt was placed over a pulley attached to the mandrel of a lathe, and both ends of the belt made fast to loaded levers, by means of which the tension in the belt could be adjusted. One lever end was attached to a spring balance, and, on rotating the pulley, the friction lifted the load on this lever and registered a pull on the spring balance attached. The other end of the belt remained under the tension due to the loaded lever at its end. The values of the tension on the two sides of the friction pulley being thus observed, the co-efficient of friction could be calculated.

The materials tested included ordinary leather, balata, cotton, and several hair belts. The following values were obtained for the co-efficient of friction and the stretch, the figures being tabulated for a tension of 200 lb. per inch width and for 800 lb. per square inch. The width of all the belts was 4 in.

Tests of Belting Materials

Total load (200 lb. per inch width))= 800 lb.:

Material.	Area in sq. ins.	Coeff. of friction	Stretch per cent.
Ordinary leather......	1.07	.34	3.2
Rawhide	.58	.38	2.5
Balata	.98	.54	1.6
Cotton	1.16	.28	1.3
Ordinary hair belting.	1.32	.24	1.9
Patent hair belting (1)	1.30	.41	1.4
Patent hair belting (2)	1.62	.79	1.4

Load 800 lb. per sq. inch:

Material.	Area in sq. ins.	Total load	Coeff. of friction	Stretch per cent.
Ordinary leather..	1.07	856	.35	3.4
Rawhide	.58	464	.66	1.3
Balata	.98	784	.54	1.6
Cotton	1.16	928	.29	1.3
Ordinary hair belting	1.32	1056	.26	2.1
Patent hair belting (1)	1.30	1040	.37	1.9
Patent hair belting (2)	1.62	1296	.80	2.0

These figures show that the advantage of the more modern belting materials over the ordinary leather is rather in the reduction of stretch than in any improvement in co-efficient of friction. They also exhibit the reason for the superiority of rawhide belting, which, although very light, stretches but little, and has a very high co-efficient of friction as long as the tension is not made too great. The behavior of the hair belting is also interesting, the ordinary belting being very similar to cotton, while the possibility of improvement by treatment is shown by the two patent hair beltings tested.

The co-efficient of friction did not prove to be constant at all tensions, nor was the behavior of all the substances the same with regard to the influence of the tension on the co-efficient of friction.

French Fuse.—The fuse of the famous 75 field gun consists of a sealed tube of tin containing burning composition, wound in a spiral round the head of the shell. In the head of the shell are holes communicating with the explosive within. The fuse is set by piercing it in a special machine which forces the sealed tube through the hole in the shell head at a point depending on the time after firing that the shell is set to explode. When the flame of the burning composition reaches the pierced point it ignites the explosive.

What to Ask For.—Get the habit of ordering drills by their diameter in decimals. Don't try to remember the numbers of drill gauges that never should have been made.

Plating and Polishing P ant of the Russell Motor Car Co.

By Walter S. Barrows*

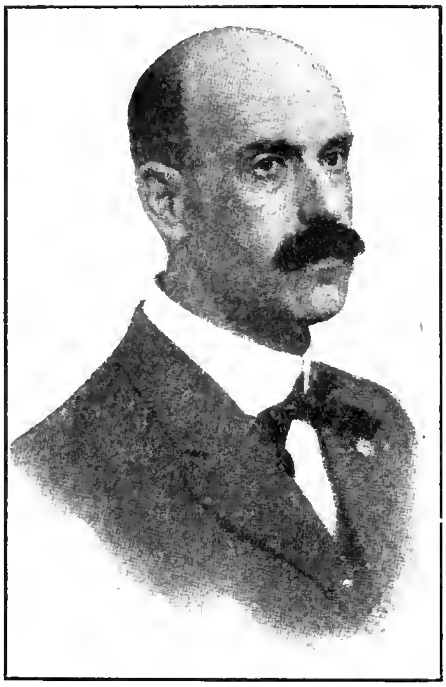
The product of this company at West Toronto, Ont., has always been characterized by its excellence of finish. Few people are aware of the scientific knowledge and practical skill necessary to insure continuous successful operation of a plating plant. Again when the actual quantity of work produced is taken in consideration, the necessity for efficient equipment and help becomes increasingly evident if required output is to be maintained.

THE plating and polishing departments of many industrial plants are usually the least interesting features shown the visitor. This fact is contrary to what one might expect. The plating and polishing department of the Russell Motor Car Co.'s Works at West Toronto is, however, an exception, and enjoys the distinction of being the finest in Canada. The cleanliness of this department has created considerable comment among men who know the existing conditions in similar departments throughout the North American continent.

Electrical Equipment

The equipment generally is very complete, the high quality of product required necessitating the installation of none but the most modern and efficient apparatus. The electrical units consist of two direct current dynamos, one supplying current at 10 and 5 volts with a three-wire system, and the other supplying a 6-volt current.

The latter is a shunt wound multipolar machine having a capacity of 2,500 amperes, and is operated in connection with a 3,500 gallon nickel solution. The copper plating tanks, brass plating baths, mechanical platers, etc., are supplied with 5-volt current from the first mentioned dynamo, while the 10-volt circuit from the same machine is employed in the operation of electro-cleaning solutions, and experimental baths. The capacity of this three-wire dynamo is 1,800 amperes. The entire power section of the department is separated from the



WALTER S. BARROWS.

plating section by glass partitions, the polished metal parts of the machines, and all connections, bus bars, etc., within the power section being kept scrupulously clean and bright.

Each tank in the plating room is connected to a voltmeter, portable ammeters being used on all tanks, while the rheostats of the rectangular switch board type, are so wired as to permit the use of suitable current densities without undue heating.

Nickel and Copper Baths.

The nickel baths average 225 gallons per tank, and are nearly all of the double row type employing three rows of anodes. Upwards of 4,000,000 bicycle spokes are plated annually in still solutions, the result being a practically rust proof spoke the reputation of which has spread to all parts of the world.

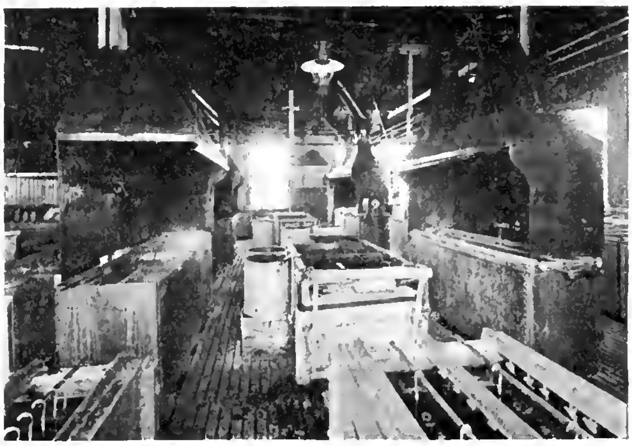
A cyanide copper solution of 600 gallons is used in copper plating all steel parts previous to nickel plating. The copper plate is exceptionally heavy and durable, no competition or rush orders being allowed to interfere with the recognized standard of plating in this establishment. Exceptional care is taken in the preparation of all parts before treatment in the plating solutions, over 700 gallons of alkaline cleaning solutions being employed for this purpose. Electric cleaners with double throw switches are operated with a 10-volt current.

The famous "solid brass" plating produced by this company is the result of persistent efforts on the part of the foreman in charge. Copper and zinc anodes are used in the brass bath, and the electrolyte is a very simple and inexpensive solution.

Plating Small Parts

Bicycle spoke nipples, and parts of similar size are plated in mechanically operated cylinders, rotated while immersed in a concentrated nickel solution.

SHOWING ARRANGEMENT OF NICKEL BATHS. POWER SECTION IN BACKGROUND.



COPPER PLATING AND CLEANING SECTION SHOWING ACID JARS AND SWILLING TANKS.

*Foreman, Electro-plating Dept., Russell Motor Car Co., Ltd.

This treatment produces polished and plated parts in large quantities with a minimum of labor.

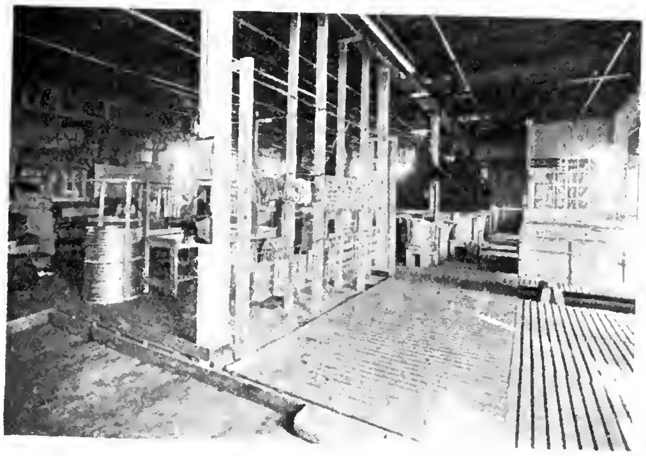
The plating room while located on the third floor is supplied with an excellent drainage and ventilation system. The floors are of concrete faced with asphalted tar paper, and protected by wooden slats. All water is conducted to a drain at the centre of the floor, and the department is well flushed and scoured once each week. Ventilation is effected by means of hoods placed above each tank containing solutions from which emanate strong fumes or steam during operation of the bath. The larger of these hoods are connected direct to outside draft, while the smaller hoods are connected to a rotary suction fan.

Parts for between 20,000 and 30,000 bicycles are plated annually, together with parts for 120,000 skates, and thousands of automobile parts. Special solutions are operated for special lines of work and the latest developments in electroplating are put to a severe test. The department is equipped with a chemical laboratory for the study of various solutions, and the perfecting of ideas which may be of commercial value to the business. The recent tests of cobalt plating solutions carried on at this plant have added a new and valuable chapter to modern electro-plating literature. Upon entering this very interesting department the visitor is impressed with the neat and clean appearance of everything, each employee being trained to do his share toward maintaining system, efficiency and cleanliness. A ball burnishing and wet tumbling section is included in the plating room. Here aluminum and steel parts are economically processed preparatory to plating. One of these tumbling barrels is the largest barrel operated in any plating department in Canada, it having a capacity of approximately 200 gallons.

Polishing and Buffing

The polishing, grinding and buffing department is located on the same floor with the plating room, but separated from the latter by a storage room. In the polishing room 35 men are employed, and the working conditions are as nearly ideal as modern ventilating machinery will permit. The blower system is worthy of particular attention as it is unusually large and efficient. The sanitary condition being well taken care of. The room is airy, well lighted and kept clean and neat in every detail. The polishing machinery is operated by separate motor power, and the entire department is being equipped to facilitate heating by exhaust steam.

In the manufacture of automobiles, bicycles and skates, the necessity for care and skilled workmanship exists in every department, but if the final finish of enamel or plating is not satisfactorily effected the product cannot become a leader in its respective line. All the products of this company are protected and finished "up to a standard not down to a price."

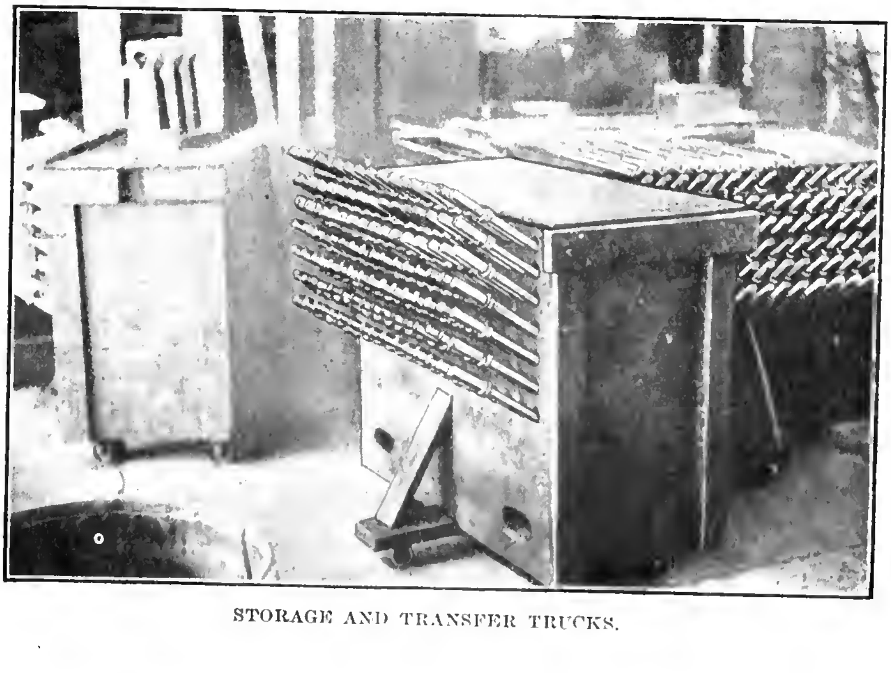


GENERAL VIEW OF PLATING ROOM FROM ENTRANCE. FINISHED WORK SECTION IN LEFT FOREGROUND.

STORAGE AND TRANSFER TRUCKS.

By G. Lock

THE trucks here shown, are used by the Henry & Wright Co., Hartford, Conn., to hold finish-ground drilling machine spindles. Kept in this way the spindles may be easily run wherever wanted, are free from danger of being "bruised", and at the same time are convenient to get at. The inside of the box-body has sloping shelves with heavy cleats to separate the spindles. The same idea is applicable to numerous other kinds of work.



STORAGE AND TRANSFER TRUCKS.

ELECTRICITY FROM BELT SLIP

THAT the unavoidable slight slip of all running belts on their pulleys produces static charges of electricity in these two bodies has often been remarked, and it has sometimes been suggested that this has been the cause of mysterious explosions in powder works. Interest, therefore, attaches to a simple device for removing this charge, described by W. T. Estlick, in the Electrical Review and Western Electrician.

It was used in a textile mill where cotton looms were running with rubber work, so that it was necessary to keep the room perfectly dry. These conditions caused the accumulation of large charges of electricity in the belts of the motors driving the looms, with the result that the belts attracted all the particles of lint floating about, eventually shaking them on to the yarn and making the work dirty. The bits of lint would also gather in the motor, and when this was blown out would settle on the work.

On two occasions also a squirrel-cage motor burnt out, apparently from no other cause than that of the charge in the rotor discharging to earth by sparkling across on to the stator winding and puncturing the insulation. Copper strips connected to earth were then placed above and below the belt, brushing lightly against it. After this no more burning out occurred, and the collection of the particles of lint was also prevented.

"GASOL," a semi-natural gas, is being introduced as a substitute for acetylene and hydrogen for autogenous welding.

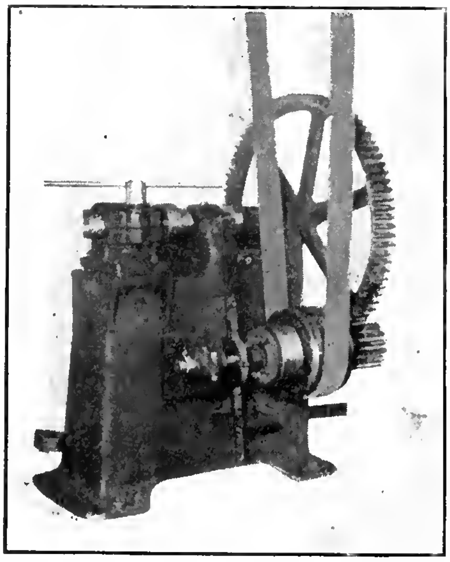
PROGRESS IN NEW EQUIPMENT

A Record of New and Improved Machinery and Accessories for the Machine, Pattern, Boiler and Blacksmith Shops, Planing Mill, Foundry and Power Plant

DRIVING HOME H.E. SHELL BASE PLATES

A MACHINE of entirely new design for use in plants making high explosive shells has been developed and built by the Holden-Morgan Co., Toronto. Until the appearance on the market of this machine, the plug has had to be screwed into the shell base by means of a hand wrench, a somewhat slow and laborious method. The accompanying illustration shows clearly the main features of the machine and the following brief description will serve to explain the design and method of operation.

The bed of the machine is a hollow iron casting supporting two bearings for the spindle and a table for the vise. At the side of the bed, low down, are two brackets holding a shaft with a pinion, pulley and friction clutch. The pulley is driven direct from the main shaft by a 4-in. belt, and is continuous running, no countershaft being necessary. A large spur gear is keyed on the end of the upper spindle, the gear wheel being driven by the pinion on the clutch shaft. At the end of the spindle is a chuck made to take the square end of the base plug. In front of the coil spring is a collar fastened to the spindle and against this collar are two fingers or prongs operated by foot lever in front of the machine.



MACHINE FOR DRIVING HOME H.E. SHELL BASE PLATES.

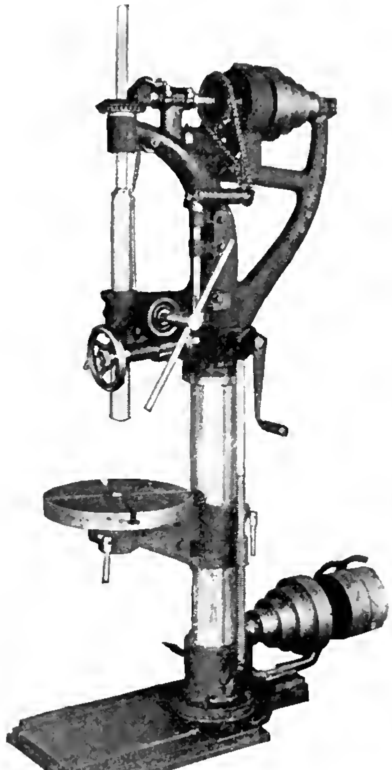
The operator having first entered the plug in the base recess, places the shell in the vise with the square end of plug in the chuck. By means of the foot lever he draws the spindle back and with it the gear wheel and chuck, at the same time pressing the shell towards the chuck. When the spring is closed, the shell is tightened in the vise and the clutch at the side thrown in, and while the spindle is revolving, the plug is being screwed into the shell base. At the same time, the spindle is being forced towards the shell by the spring, thus following up the plug as it enters the base. By this arrangement it is impossible for the end of the plug to come out of the chuck. When the plug is driven home the tension is thrown back to the clutch which slips, and the operator throws it out.

The friction device on the clutch is adjustable and can be set for any desired tension. When set, the pressure applied will not vary from the desired adjustment. The whole operation, being mechanical, eliminates the variations that result when the plugs are screwed in by hand. The machine is of simple design and substantial construction and contains very few parts that can get out of order. It is perhaps the most efficient labor and time saving machine that has been put on the market since the manufacture of shells was first started.

DRILL WORKER ON H. E. SHELLS

AT the shell plant of Canadian Blower & Forge Co., Berlin, Ont., what is known as their "Canadian" 20 in. drill has been adapted for all of the lighter operations in place of the heavier type of machines. The drill is giving especially good service on sizing the threads. On the British 18pdr. high explosive shell, there is a thread 1¼ in. long on the inside, and of 2 in. diameter No. 14 whitworth gauge right hand. This thread must be acurately sized with a variation of not more than .002. The drill referred to is we understand doing this work with perfect accuracy and cutting a clean thread. It is further equipped with a milling cutter which re-sets the bevelled surface at the end of the shell on which the fuse rests.

For reaming the sides and finishing the bottom a modification of the standard drill has been made. The automatic power feed-travel-spindle has been increased to 14½ in. and is controlled throughout its travel by an automatic trip, which can be adjusted for any predetermined depth. The tripping mechanism which is on the hand lever shaft is new and novel and does away with the spindle sleeve clamp type of trip. The new arrangement permits a length of automatic feed equal to the full travel of the spindle. The single feed of .030 of an inch per revolution of the spindle for this particular drill is positive and is obtained through two sprockets and a linked chain. Three stop cones can be substituted for the chain drive and speeds of .004 to .007 and .012 of an inch obtained. The drill has hand, lever and automatic feeds, so that practically any condition of feed can be met.



DRILL FOR LIGHTER OPERATIONS ON H.E. SHELLS.

The crown gear runs in a renewable bronze bushing thereby eliminating bother and expense of rebabbitting with the chance of getting the spindle out of alignment. The drill spindle has a No 4 "Morse" taper, and the key drift slot is below the sleeve, so that the key drift can be used with spindle in any position. The greatest distance from the spindle nose to the table is 20½ in., and from the nose to the base 36½ in.

CARTRIDGE CASE TRIMMING LATHE

THE Canada Machinery Corporation, Galt, Ont., have placed on the market a lathe which has been specially designed to finish the British 18 pdr. shrapnel

cartridge case, and also the 4½ inch British howitzer cartridge case. The lathe work necessary to be performed, is accomplished at one chucking of the case.

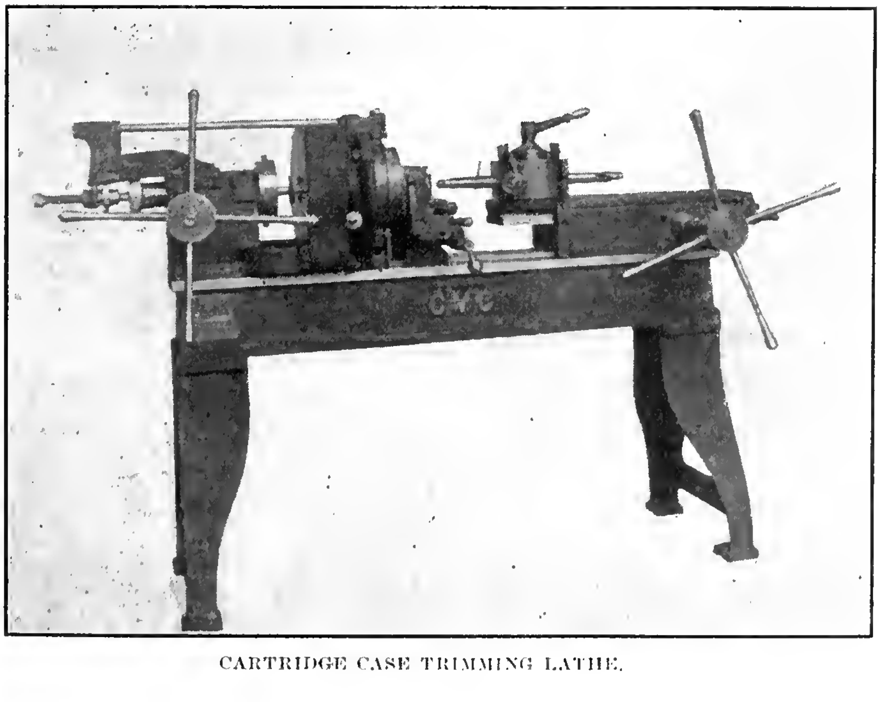
The spindle is made about ¾ in. less in length than the shrapnel cartridge case, allowing thereby the ends of the latter to project so that machining may be performed at both ends. The spindle and pulley are in one piece, and the spindle runs in a cast iron bearing sleeve, which is gripped tightly in the head by means of the top cap. At the front end of the spindle, a lever operated chuck is carried. This chuck has two sets of jaws, one for shrapnel cases, and one for howitzer cases. The chuck can be adjusted by means of a nut in order to make it grip firmly, should any slight variation occur in case diameters.

The chuck lever is in a convenient position at the front of the head, and the continued movement of this lever after releasing the chuck operates an ejector rod for ejecting the case out of the chuck when finished. This ejector rod is also used as a stop rod when putting the cases into the spindle, in order to give the correct projection of the head of the case front of the chuck. An adjustment is provided on this stop rod by means of lock nuts at the rear of the head. A cross slide operated by means of a ball handle and screw is provided with back and front form tools for forming the shape of the head, and with a facing tool having an independent adjustment in relation to the form tools, for setting to the head thickness. Dead stops with a fine adjustment are provided for the cross slide.

The tools for boring, recessing and threading the hole in the head of the case, are carried in a four tool turret. This turret has an automatic revolving motion operated by means of the backward movement of the pilot wheel. For boring out the mouth of the cartridge case and facing off the end to the proper length, a back cutter head is carried in the headstock, and is traversed by means of the pilot wheel, pinion and rack shown at the rear of the head. The cutter head is traversed forward until the stop on the back of its sleeve strikes the boss at the back of the head. This stop is adjustable on the sleeve and governs the length of the case trimmed. One facing tool and one boring tool are carried in the back cutterhead, the boring tool being provided with fine adjustment for diameter. A leather disc is also carried in front of the rear end cutter head to clean out the cuttings from the mouth of the case, preventing them from lodging in the inside of the spindle.

The mouth of the case is centered in the rear of the spindle by means of a floating centering collar, which provides for any slight variation in case mouth diameter. The lubrication of the spindle has been given special attention, oil being carried to the spindle bearing by means of a felt pad from an oil reservoir at the bottom, in addition to a sight feed lubricator on top.

This machine it is claimed will finish British 18 pdr. cartridge cases at the rate of twenty-five per hour.

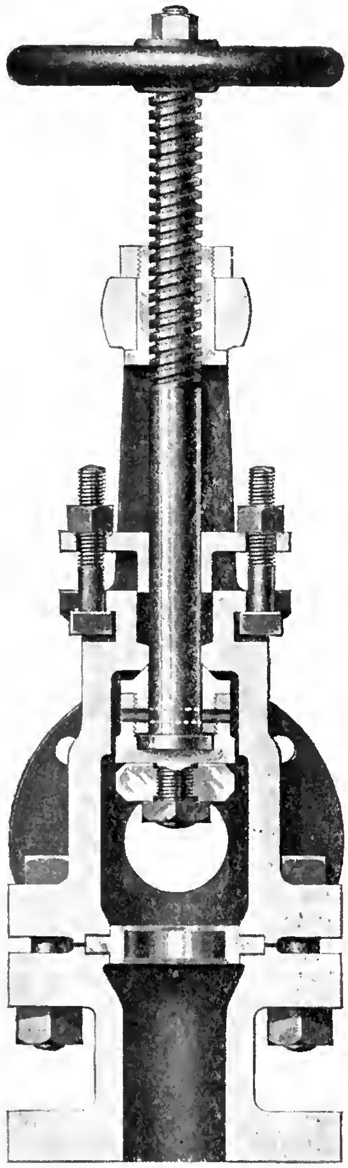


CARTRIDGE CASE TRIMMING LATHE.

RENEWABLE BLOW-OFF VALVE

ONE of the most notable evidences of the safety first movement is observable in the increased precautions which are now taken to insure absolute safety in the operation of boilers. Among recent developments, the adoption of double valves on the blow-off pipe has called forth new examples of the valve-maker's art.

The Homestead Valve Manufacturing Co., Inc., of Homestead, Pa., have designed and placed on the market an angle type of blow-off valve, under the name of the "Hovalco." The double valve arrangement usually consists of two valves of different types, say a plug cock and an angle valve, or a gate valve and an angle valve. The "Homestead" valve, which is of the plug-cock design, has been favorably known for many years, and it was the company's desire to supplement this in order to meet modern conditions, which led them to produce the angle type valve shown in the illustration.

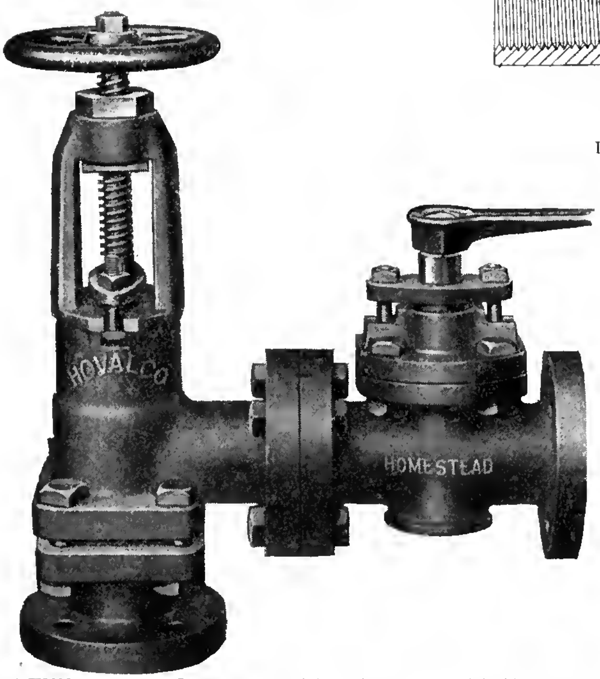


SECTION OF REGRINDING AND RENEWABLE BLOW-OFF VALVE.

The valve is of the re-grinding and renewable description, and combines high-grade materials with excellent design and manufacture. Both the disc and seat are of monel metal, the anti-

corrosive properties of which make it particularly suited for this work. In addition to being of the re-grinding type, the design of the valve is such that both disc and seat can be quickly reversed, thus practically doubling the term of service before repairs are necessary.

The body of the "Hovalco" valve is made of semi-steel and all trimmings of high-grade bronze. All-bronze valves can be supplied also. Access to the interior is obtained by removing four bolts



RENEWABLE BLOW-OFF AND QUARTER TURN VALVES.

which hold the parts of the valve body together. Some State authorities have already passed laws requiring double blow-off valves and combinations of the nature described, by means of which the angle valve can be renewed, reground, or overhauled by simply closing the quarter-turn valve, thus avoiding closing down the boiler or other interference with plant operation.

THE "DEAN" BOILER TUBE CLEANER

THE "Dean" Boiler Tube Cleaner possesses the unique feature of being adaptable for use in either water tube or return tubular boilers. By simply changing the vibrator head or hammer, the cleaner becomes equally efficient in removing scale from the interior or exterior of boiler tubes. The device is purely vibratory in its action, being therefore entirely free from any boring, scraping or other cutting or frictional action.

A sectional view of the apparatus is shown in Fig. 1, from which it will be seen that the vibrating head might be likened to a power operated pendulum, and its effect on the walls of the tube is to create a state of localized vibration or tremor such as is caused in a bell when struck by the clapper. Owing to the difference in hardness and strength between hard scale and steel boiler tubes, the scale is physically unable to vibrate at the high speed of the steel. Consequently, the surfaces in contact are separated from each other almost immediately, and a continuance of the vibration produces an internal disintegration of the scale causing it to fall away from the tube surfaces in small pieces, which, in the case of water tube boilers, are expelled from the tube by the exhaust air or steam which operates the cleaner.

This peculiar action renders the "Dean" tube cleaner particularly efficient in removing scale from corners, crevices, or joints which are difficult of access.

Referring to Fig. 1, the vibrator (a) is hinged at (b), and carries at its outer end, the vibrator head (c), while the other end is formed so as to operate in

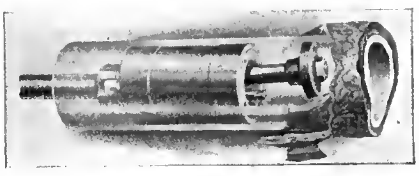


FIG. 3. REMOVING SCALE FROM OUTSIDE OF BOILER TUBE.

valve (d). The hinge (b) is carried by body (e) in which are formed passages (f), one end of which is controlled by valve (d), the other ends entering cylinder (g) at opposite ends. Piston (h) surrounds vibrator (a), a ball and socket arrangement being provided so that vibrator (a) may be moved by piston (h).

With the vibrator head in the lever

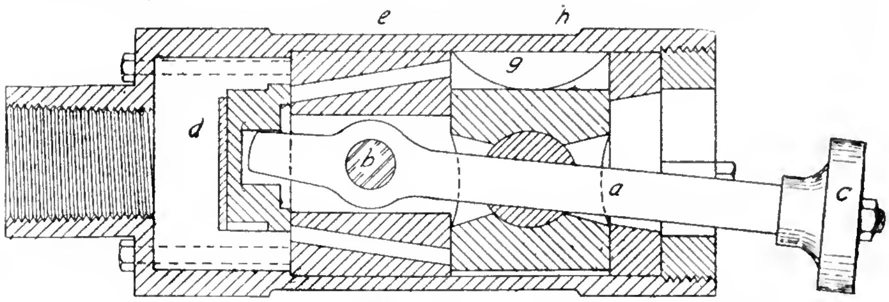

FIG. 1. SECTIONAL VIEW OF "DEAN" BOILER TUBE CLEANER.

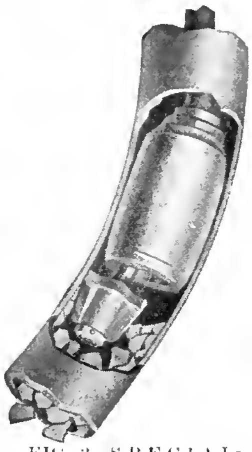

FIG. 2. SPECIAL TYPE OF CLEANER FOR "STIRLING" BOILER TUBES.

position as shown, the valve admits the working fluid to the lower end of the cylinder whereupon the piston is instantly forced upward carrying the vibrator with it, and causing the head to make impact with the upper side of the tube. The action of the vibrator causes the valve to travel downward and uncover the upper passage to the cylinder, thus returning the piston to the position shown.

The tapping action takes place at the rate of from 3,500 to 10,000 times per minute and gives rise to the series of vibrations in the boiler tubes which result in the scale automatically detaching itself from the surface. Again, the vibratory movement can be regulated to such a mechanical nicety that at the highest possible speed the tube is not subjected to hammering in the usual sense of the word—a gentle tapping of very high frequency being what actually takes place.

The actual force of the tap is equival-

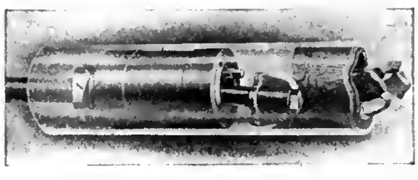

FIG. 4. REMOVING SCALE FROM INSIDE OF BOILER TUBE.

ent to 2½ foot ounces, and with 70 to 90 lbs. pressure it vibrates at a speed of 5,000 to 8,000 times per minute. The Dean cleaner is manufactured by the William B. Pierce Co., of Buffalo, N.Y.

All literature is advertising, and all genuine advertisements are literature. The author advertises men, times, places, deeds, events and things. His appeal is to the universal human soul. If he does not know the heart-throbs of men and women, their hopes, joys, ambitions, tastes, needs and desires, his work will interest no one but himself and his admiring friends.

AN UNEXPECTED VERDICT

THE tenor of the speech given by D. A. Thomas before the Montreal Branch of the Canadian Manufacturers' Association on Friday last cannot be described as reassuring from the viewpoint of Canadian shell makers. While all loyal manufacturers must hope that Mr. Thomas' meaning has been misinterpreted, the fact that Major-General Sir Samuel Hughes has taken exception to several inferences, would indicate that Mr. Thomas' visit to Canada is utterly barren of those results which many of us had so fondly anticipated.

Coming as it did soon after Lord Curzon's unfortunate contretemps in the House of Lords in connection with Canada's supply of munitions, the visit of the Welsh magnate was expected to counteract the temporary pessimism induced by the noble lord's remarks. Hope ran high regarding the happy impression which personal observation would make upon the visitor, and coming as he did in the capacity of personal representative of Lloyd George, the least that could be looked for was that our methods and our men would appeal more strongly than ever to one whose business capacity had brought him into such direct contact with the British Minister of Munitions.

Either the ability of Canadian munition makers has been grossly exaggerated or Mr. Thomas' qualifications as official observer are decidedly over-rated. Strictures such as he is reported to have made regarding unsatisfactory delivery, and allegations as to higher prices demanded would never have been made by a person acquainted with the real history of shell making in this country.

If the personal qualifications necessary for the successful control of large business interests, the ability to judge men, observe conditions, weigh up past performances, and deduce future accomplishments had been freely exercised, above all if the intense desire and obvious capacity of Canada to render a creditable account of herself in supplying munitions had been fully appreciated by Britain's Envoy, the present regrettable controversy would never have developed.

One of the first principles in controlling labor, and it applies to firms as well as individuals, is to pile up the work ahead to such an extent that there is no time to think of what is going to happen when the immediately present job is through. No one knows when the war will be finished, but everyone knows that while the war lasts, shells will be needed, and needed badly. We do not say that the supply of shells from this country will continue till the actual conclusion of hostilities, but what we do say is this: If the supply of shells from Canada is to continue for an indefinite period, we ought to know it and know it now.

While exact information regarding results in British factories is unavailable, there can be no doubt in the minds of our manufacturers here regarding the results of a comparison. Consider the difference in conditions. Thousands of miles from the source of the business, the conspicuous absence of instructors and advisors, the altogether conspicuous presence of inspectors and ultra-rigid specifications, latterly the omnipresent but oft delayed vision of completed contracts and idle factories,—consider all these things in the light of industrial enlistment so strenuously being carried out in Britain, and then consider how Canadian manufacturers as a body continue to maintain an attitude of solicitous effort in their desire to render service to the Empire.

If there still remains any doubt as to the loyalty of Canada's efforts, the fullest refutation is contained in Major-General Hughes' statement: "No shells whatever were produced in England by commercial organizations until months after Canada had made delivery. Not one shell was produced in any commercial institution in the United States until long after Canada had been producing enormous quantities. Canada's Shell Committee has led the world in this line. The regular manufacturers of war material in the United States and Great Britain were also far behind the Canadian commercial industries relatively, in their deliveries. The Canadian Shell Committee . . . . was not free to enlarge its sphere of action. Had it received large orders at the beginning it would have been able to rival the entire output of the United States and Britain in quantities, but the orders came piecemeal, and each was supposed to be the last."

The General Market Conditions and Tendencies

This section sets forth the views and observations of men qualified to judge the outlook and with whom we are in close touch through provincial correspondents.

Montreal, Que., Oct. 9, 1915.—The end of the first week in October sees the demand for steel bars and billets still on the increase; in fact, indications point to a still greater demand for billets suitable for the production of larger shells. Several large concerns have been discussing renewals of foreign orders, bids for 6-in., 8-in. and 9.2-in. shells being also under consideration. In the meantime it is altogether likely that further orders for the smaller sized shells will continue to be placed.

It is expected that in a short time the Shell Committee wil be reorganized and enlarged and with the assistance of Sir Frederick Donaldson, who is on his way here from England, an added impetus and activity will be given to the work. It is possible that within a short time the establishment of a large central ordnance factory will be given serious consideration, and if decided upon would eventually come under the direction of the Canadian Government.

Steel

High tension operation at our steel mills still prevails. In some instances steel producers are forced to turn down orders, being unable to make deliveries within a reasonable time. As usual, the demand for rounds and billets for war munitions predominates. Quotations for plates, shapes and bars are irregular, owing to uncertainty of delivery.

Metals

Quotations on the various metals are still holding firm and little change is to be noted in this week's prices. Tin, however, shows a decline of 2 cents per pound.

Machine Tools and Supplies

The condition of the machinery trade continues to keep dealers of uncertain mind in the matter of delivery, although appearances point to more favorable immediate outlook in the latter respect. The demand for supplies continues brisk.

Toronto, Ont., Oct. 12.—Trade conditions continue to gradually improve and indications point to further increases in the export trade of the Dominion. This is an encouraging feature as the favorable trade balance which has resulted will benefit the country considerably and put business generally on a more stable basis. The development of the export business is of course due to the large orders for war equipment, and there is every reason to believe that there will be a steady stream of these orders for some time to come. The result of the war business will mean general increased prosperity and an improvement in economic conditions.

As regards domestic trade, business is quieter, and, owing to prevailing conditions, few new enterprises are being started except for the manufacture of munitions. In this regard developments are expected in the near future, as it is understood that tentative inquiries are being considered for the manufacture of 60 pdr. and 180 pdr. shells. The making of artillery is being considered, but nothing has developed in this regard up to the present. That developments in the shell industry are promised is indicated by the announcement that two experts from England will assist the Shell Committee as technical advisers.

Steel Market

The probability of 60 and 180 pdr. shells being made in Canada will further stimulate the steel trade. The demand for steel for munitions is steadily increasing and the mills are working to capacity. The market for bars is very firm and an advance may be expected any time. Owing to the increased cost of raw material, prices of cold drawn steel shafting have advanced, the discount off list being 5 per cent. lower. Steel boiler tubes have advanced, the new quotations ranging from $1 to $2 higher per 100 feet, according to size. Wire rods are higher, being quoted at $31 Pittsburg.

Galvanized sheets continue irregular, the tendency being towards lower prices, although it is hardly probable that the low levels will be maintained. The shortage of semi-finished steel is a problem that galvanized sheet manufacturers will have to face, and although spelter is lower than it was some time ago, the price is still too high to be attractive to consumers. Painted sheets are being used instead of the galvanized product which has affected the market for the latter to a considerable extent. The revised prices for sheets are given in the selected market quotations.

There is an extraordinary demand for nearly all kinds of steel products in the States. Some of the larger mills are reported to be turning down nearly as much business as they are accepting, being unable to make the deliveries wanted. A tremendous demand for steel bars for shells continues and inquiries aggregate an enormous tonnage, the market being practically sold out for this year. Prices are advancing and bars, plates and shapes are now quoted at $1.40 Pittsburg.

Pig Iron

The market for foundry iron is still very quiet, but the demand for steel making pig iron is increasing. The market for standard low phosphorous iron is buoyant and there is an increased demand for this grade in Canada; a considerable tonnage being imported from the States. Quotations are firm, but unchanged.

Old Material

The market is weaker for copper and brass, and prices are slightly lower. Heavy melting steel and wrought iron are stronger on good demand and prices have advanced 50c per ton, lead and zinc are quiet and prices unchanged. Prices are given in the current quotations.

Machine Tools

The probability of orders being placed for larger shells has stimulated the market. Tentative enquiries are being sent out for larger lathes than have hitherto been used. The shells are of the high explosive type and range from 6 in. diameter upwards. Lathes of 24 in and 30 in. swing will probably be required for the work. Large orders for this equipment have already been placed with builders in the States by British, French and Italian agents. It is therefore possible that some difficulty will be experienced now in obtaining a sufficient num-

---

EQUIPMENT FOR AUSTRALIAN RAILWAYS.

Tender forms, specifications and drawings have been forwarded by Commissioner D. H. Ross, Melbourne, for equipment required by the Victorian and Queensland Government Railways. These tender forms will be open to the inspection of Canadian manufacturers when received at the Department of Trade and Commerce, Ottawa (refer File No. 1435). Particulars of the requirements, together with the date on which the tenders close at Melbourne are briefly outlined thus:—

Victorian Railways.

No. 29,410. November 24.—2 duplex boiler feed pumps as specified.

No. 29,421. November 24.—750 sq. yds. compressed felt as specified.

Queensland Railways.

Tenders close at the office of the Queensland Railways, Brisbane, on November 2, 1915, for 10—30,000 gallons conical wrought iron tanks.

The departure of mails from Vancouver are indicated thus:

From Vancouver, October 27, due at Melbourne on November 20.

ber of heavy lathes for immediate delivery. There is still a good demand for second-hand equipment and increased activity is anticipated for lathes of this class.

Supplies

Business continues brisk and prices have an upward tendency. There has been an advance of approximately 5 per cent. in bolts and nuts. Cap and set screws are also higher. Linseed oil has again advanced 2c per gallon and is now quoted at 74c for raw and 77c for boiled oil. Revised prices are given in the selected market quotations.

Metals

The market generally is steady and there is nothing of particular interest to report. There are no price changes to note this week, the markets being dull and featureless. The demand for metals for munitions continues brisk, but ordinary business is comparatively quiet.

Tin—Both London and New York markets are dull and unchanged. There is very little business doing, both buyers and sellers awaiting developments as there is a possibility of an export duty being levied on tin by the British Government. Quotations are unchanged at 38c per pound.

Copper—The market it quiet and unchanged, but in good condition. Producers generally are satisfied with the situation, and while the demand is dull at present, increased activity is expected in due course. Quotations are firm and unchanged at 19½c per pound.

Spelter—The market is dull and easy, with a lower tendency. The demand is light and consumers are not showing much interest. Quotations are unchanged at 18c per pound.

Lead—The market is very steady, there being no change of any sort. This metal continues in good demand. There is an impression in the trade that no official change in price is likely in the near future. Lead is quoted locally at 6¼c per pound.

Antimony—The situation is unchanged and market dull. Quotations are nominal at 35c per pound.

Aluminum—There is nothing of particular importance to note in this market. Supplies are still very scarce and quotations nominal at 55c per pound.

C.P.R. ANNUAL METING

THE thirty-fourth annual meeting of the Canadian Pacific Railway Co. was held in Montreal on Oct. 6, the president, Sir Thomas Shaughnessy, in the chair. The business dealt with consisted of the presentation of the annual report, the adoption of the annual financial statement, and the election of officers. Directors re-elected were: R. B. Angus, Montreal, Sir Herbert S. Holt, Montreal, and Sir Edmund Osler, of Toronto. Colonel F. G. Meighen, of Montreal, was elected to fill the vacancy left on the directorate by the death of Sir William Van Horne. The shareholders also adopted a resolution empowering the absorption of the Allan Line Steamship Co.

In the course of his address Sir Thomas Shaughnessy remarked that the company's annual statement was in some respects the most unsatisfactory submitted in a number of years. The shrinkage of $31,000,000 in the gross earnings was in excess of the entire gross earnings for 1901. Notwithstanding this falling off in revenue, the regular dividends had been earned, evidence of the foresight of the company in making such expenditure in the past ten or twelve years as to enable it to make a saving in the working expenses and offset the loss.

The physical condition of the company's property had never been better, while traffic had been handled more expeditiously and economically. He thought they could look forward to the future with buoyant confidence, as everything pointed to a marked improvement in the company's revenue during the current fiscal year. The country had been blessed with a most bountiful harvest and the field crops harvested in the four provinces west of Lake Superior will yield per capita to their civil population more than twice as much money as the rural population of the eight States directly south of them received per capita in 1914.

The company's land sales were 77,000 acres in the last three months, compared with 41,000 in the same months last year. Mining and lumber activity in the West indicated a partial restoration of confidence. It was to be hoped that in anticipation of the end of the war an organization would be perfected for unity of action between the Dominion and Provincial Governments and the important business interests of the country in regard to the immigration of agriculturists and the comprehensive development of the natural resources of Canada.

Sir Thomas said that, until the money market improved, no especial effort would be made to dispose of any portion of the four per cent. consolidated debenture stock, amounting to $40,000,000, and representing advances made by the company's treasury for additional mileage, as there was on hand sufficient money to meet all requirements for a considerable period.

CANADIAN GOVERNMENT PURCHASING COMMISSION

The following gentlemen constitute the Commission appointed to make all purchases under the Dominion $100,000,000 war appropriation:—George F. Galt, Winnipeg; Hormidas Laporte, Montreal; A. E. Kemp, Toronto. Thomas Hilliard is secretary, and the commission headquarters are at Ottawa.

ALLIES PURCHASING AGENTS

The Trade and Commerce Department, Ottawa, has published the following list of purchasing agents for military purposes for the allied Governments:

International Purchasing Commission, India House, Kingsway, London, Eng.

French.—Hudson Bay Co., 56 McGill Street, Montreal; Captain Lafoulloux, Hotel Brevort, New York; Direction de l'Intendence Ministere de la Guerre, Bordeaux, France; M. De la Chaume, 28 Broadway, Westminster, London.

Russian.—Messrs. S. Ruperti and Alexsieff, care Military Attache, Russian Embassy, Washington, D.C.

DOMINION STEEL CORPORATION

SIXTEEN months ago the Dominion Steel Corporation had pressing obligations of $5,500,000. By the close of the current year, according to a statement of one of the directors, this debt will be practically all wiped out. Advances to banks will be repaid, the notes due November 1, amounting to $1,500,000, will be met, and the company expects to be in a position to pay dividends after the close of the year. The following table shows the company's position:

Obligations 18 months ago:	
Notes	$1,500,000
Due banks	4,000,000
Total obligations	$5,500,000
Obligations July 31, 1915:	
Notes	$1,500,000
Due banks	2,300,000
Total obligations	$3,800,000
Account credit company in banks	1,400,000
	$2,400,000

This debt of $2,400,000 will be wiped out by actual and estimated earnings of the company during the last five months of the current year. Export trade comprises the bulk of operations. Orders have been heavy for bars, billets, wire and nails, and contracts for toluol have

proved exceptionally profitable. The coal trade has been the best in the history of the company. In addition to this, the company is now working on a special Government contract amounting to $1,500,000.

NOVA SCOTIA STEEL & COAL CO.

AT the meeting of the directors of the Nova Scotia Steel & Coal Co., held at New Glasgow, N.S., on September 29, the general manager submitted a statement relative to the business of the company which was considered most satisfactory. The output of shells for September was the largest of any month since the manufacture of munitions was begun, being 40 per cent. over that of August. It was reported that the orders on hand would keep the company at the present high rate of production for at least six months, and that negotiations for others were in progress.

Although it is understood that important matters relative to the financing of the company were taken up by the directors, no statement could be obtained. At the conclusion of the meeting it was stated, regarding war orders, that, in addition to other large orders which are being negotiated for, a large car contract was expected to be signed shortly.

The meeting was attended by Lieut.-Col. Thomas Cantley, president; W. D. Ross, vice-president; the Hon. J. D. McGregor, J. Walter Allison, George S. Campbell, W. H. Chase, Frank Stanfield, R. F. Chambers, and James C. McGregor. In the morning the directors made a tour of the company's plant.

Woodstock, Ont.—The ratepayers are asking the council to compel the Woodstock Gas Light Co. to supply purified gas. It is suggested that purifiers be installed by the company.

CANADA STEAMSHIPS

THE Canada Steamship Lines is bringing several of the grain boats which went into Atlantic service in the spring back to the Great Lakes for the movement of the Western harvest. The company reports that it will be in a position to handle the usual volume of grain before the close of navigation, and the statement has been heard that the boats of this concern alone could probably handle a sufficient volume of the Western output to keep the Montreal elevators busy.

The tourist season on the lakes is now about over. It is understood that the passenger traffic this season has been very light and not up to what had been hoped for, even though transportation officials did not place much faith in the campaign to bring American sightseers to the north to make up for the elimination of European attractions.

Intensified Production in a Shrapnel Shell Factory

Staff Article

Prior to the advent of shell making, the products of modern machine tool builders seemed to have reached finality, not only in refinement of design and accuracy of work, but also in quantity of production. The conditions pertaining to shell work have afforded progressive manufacturers welcome opportunity for exercising individual initiative in machine design. The examples described are as interesting as their results are commendable.

SIX months ago the plant referred to in this article was completing shells at a rate of 800 per day. This was considered good, as the result of several months' work on shells.

To-day this plant completes 2,700 shells per day with practically the same number of men and machines. Considered in the light of other manufacturers' progress, the previous methods and equipment were well advanced, and any shell maker would not have offered himself for criticism had he decided at that time to leave well alone, and insure the continuous operation of the plant under the then existent conditions.

While the arrangement of the plant, generally speaking, is more or less the same as six months ago, certain changes in methods, machines, and equipment have more than trebled the output.

The changes in methods resulted in the saving of time by combining certain operations with others, either before or after. Other instances arose where it was found better to move the work instead of the tool, as in waving, for example.

Changes in machines refer to at least two specific instances where castings used in the regular business of the company were utilized in a manner very different from what they were originally intended to be. Other cases refer more to improvement in fixtures and operating devices. The principal change in equipment refers to the substitution of a chute system in place of transfer trucks.

Methods

A careful study of the requirements showed that the contour of the nose could be done as part of the rough turning on boring mills instead of as a separate subsequent operation. As performed on a "Bullard" vertical turret lathe, the rough turning is an excellent example of speed and accuracy on the part of man and machine. The square tool box on the side carriage has two turning tools, one roughing A and one sizing B. The cross slide carriage has a radius tool C, which is also used for facing across the base. The turning tool on side carriage is started at the base of the shell, which is driven on to a grooved arbor. While it is travelling downwards, the cross slide carriage is run down by rapid power and set for cleaning up the base, which has been previously roughed in a miller (see Fig. 4). By the time the base is cleaned up and the radius formed (see Fig. 1), the turning tool A has reached the point on the shell where the taper starts. The operator now feeds it out gradually by hand, producing a taper of sufficient accuracy to meet the requirements for nosing later.
